## Welcome to the TCHÊ QUÍMICA JOURNAL

*International multidisciplinary scientific journal*

*The Tchê Química Journal publishes original research papers, review articles, short communications (scientific publications), book reviews, forum articles, technical reports, articles on chemical education, interviews, announcements or letters. Articles suitable for publication in the Tchê Química Journal are those that cover the traditional fields of **Chemistry, Physics, Mathematics, Biology, Pharmacy, Medicine, Engineering and Agriculture**. We are especially interested in those submissions that are highly relevant to theoretical and applied contributions in the area of chemistry and related disciplines.*

Esta revista é indexada e resumida pelo CAS, EBSCO, Latindex, Sumários, Index Copernicus, Scopus, OAIJ, CAB Abstracts, EuroPub e Reaxys.

### Missão

O Periódico Tchê Química (PTQ) publica artigos de pesquisa originais, artigos de revisão, notas curtas (publicações científicas), revisões de livros, artigos de fórum, editoriais e entrevistas. Pesquisadores de todos os países são convidados a publicar nas páginas do PTQ.

A responsabilidade sobre os artigos é de exclusividade dos autores.

### RESUMO

Os alcaloides beta-carbolina mostram uma ampla gama de efeitos psicofarmacológicos (por exemplo, alguns alcaloides beta-carbolina facilitam a transmissão dopaminérgica e interagem com os receptores dopaminérgicos D1 e D2 no corpo estriado). Este artigo apresenta dados sobre os efeitos neuroprotetores de compostos alcaloides usando métodos de simulação em computador, triagem virtual baseada em *docking* e farmacologia experimental. O objetivo do estudo foi investigar a ação neuroprotetora / protetora contra o estresse de novos derivados de compostos alcaloides usando os métodos de simulação computacional, triagem virtual baseada em *docking* e farmacologia experimental. Com o auxílio dos programas *ChemDraw* e *MGLTools*, foram utilizados os métodos de modelagem computacional das moléculas de derivados alcaloides, triagem virtual baseada em *docking*, receptor DRD2 e modelos tridimensionais das moléculas de ligantes. A energia de ligação de uma conformação individual foi usada como resultado final, o que mostra a força da interação entre o ligante e a molécula alvo. Foram estudados 22 compostos de alcaloides e seus derivados. A modelagem virtual de moléculas foi realizada para compostos e receptores, a ligação da molécula "ligante-alvo" foi realizada e os compostos candidatos foram selecionados. Estudos experimentais *in vivo* dos efeitos neuroprotetores desses compostos foram conduzidos no modelo de estresse emocional. Foram estudados os efeitos dos alcaloides harmina, norharmane e guanina no tempo de imobilidade no teste de natação forçada em camundongos, um modelo de depressão em animais. Um teste de natação forçada e um labirinto positivo elevado foram utilizados para determinar os efeitos antidepressivos e ansiolíticos da harmina em ratos. De acordo com os resultados do *docking*, as moléculas apresentadas de compostos alcaloides apresentaram interações com o receptor de dopamina D2. Os resultados obtidos no teste "Elevated Plus Maze (labirinto positivo elevado)" mostraram que os animais tratados com 9-metoxi-2-fenil-11H-indolisino [8,7-β] indol, lappaconitina e citisina na dose de 5 mg/kg, comparados em ratos do grupo controle, experimentaram uma ação ansiolítica (anti-ansiedade) no estresse emocional experimental.

**Palavras-chave:** beta-carbolina, teste de natação forçada, triagem virtual baseada em *docking*, atividade neurotrópica.

### ABSTRACT

Beta-carboline alkaloids show a wide range of psychopharmacological effects (for example, some beta-carboline alkaloids facilitate dopaminergic transmission and interact with dopaminergic receptors D1 and D2 in the striatum). This article presents data on neuroprotective effects of alkaloid compounds using computer simulation methods, docking-based virtual screening, and experimental pharmacology. The purpose of the study was to investigate the neuroprotective/stress-protective action of new derivatives of alkaloid compounds using the methods of computer simulation, docking-based virtual screening, and experimental pharmacology. Through *ChemDraw*, *MGLTools* programs, they have used computer modeling of the molecules of alkaloid derivatives, docking-based virtual screening, DRD2 receptor, and three-dimensional models of the ligand molecules. The binding energy of an individual conformation was used as a final result, which shows the strength of the interaction between the ligand and the target molecule. 22 compounds of alkaloids and their derivatives were studied. Virtual

molecule modeling was performed for compounds and receptors, "ligand-target" molecule docking was carried out, and candidate compounds were selected. *In vivo* experimental studies of the neuroprotective effects of these compounds were conducted in the emotional stress model. The effects of harmine, norharmane, and guanine alkaloids on immobility time in the forced swimming test in mice, a model of depression in animals, were studied. A forced swimming test and an elevated plus-maze were used to determine the antidepressant and anxiolytic effects of harmine in rats. According to the docking results, the presented molecules of alkaloid compounds showed interactions with dopamine receptor D2. The results obtained in the "Elevated Plus Maze" test showed that the animals treated with 9-methoxy-2-phenyl-11H-indolizino[8,7-β]indole, lappaconitine and cytisine at a dose of 5 mg/kg, compared to rats in the control group, experienced an anxiolytic (anti-anxiety) action in the experimental emotional stress.

**Keywords:** *beta-carboline, forced swimming test, docking-based virtual screening, neurotropic activity.*

## АННОТАЦИЯ

Бета-карболиновые алкалоиды проявляют широкий спектр психофармакологических эффектов (например, некоторые алкалоиды бета-карболина облегчают дофаминергическую передачу и взаимодействуют с дофаминергическими рецепторами D1 и D2 в полосатом теле). В этой статье представлены данные о нейропротекторном действии алкалоидных соединений с использованием методов компьютерного моделирования, виртуального скрининга на основе докинга и экспериментальной фармакологии. Цель исследования – изучение нейропротекторного/стресс-протекторного действия новых производных алкалоидных соединений с применением методов компьютерного моделирования, виртуального докинга и экспериментальной фармакологии. В ходе исследования использовались следующие методы: компьютерное моделирование молекул производных алкалоидов, виртуальный скрининг на основе докинга, рецептор DRD2, трехмерные модели молекул лигандов, которые были сконструированы с использованием программы ChemDraw с использованием набора программ. Autodock (Исследовательский институт Скриппса, США), MGLTools (Исследовательский институт Скриппса, США). В качестве конечного результата была использована энергия связи индивидуальной конформации, которая показывает силу взаимодействия между лигандом и молекулой-мишенью. Было изучено 22 соединения алкалоидов и их производных. Моделирование виртуальных молекул выполняли для соединений и рецепторов, проводили стыковку молекул «лиганд-мишень» и отбирали соединения-кандидаты. Экспериментальные исследования нейропротекторных эффектов этих соединений в естественных условиях проводились в модели эмоционального стресса. Исследовано влияние алкалоидов гуарена, норхармана и гуанина на время неподвижности в тесте принудительного плавания на мышах, модели депрессии на животных. Тест на принудительное плавание и лабиринт с повышенным уровнем плюс были использованы для определения антидепрессивного и анксиолитического действия гуанина у крыс. По результатам проведенного докинга установлено, что представленные молекулы алкалоидных соединений проявили взаимодействие с рецептором дофамин D2. Результаты, полученные в тесте «Приподнятый крестообразный лабиринт», показали, что в группе животных, получавших вещества 9-Метокси-2-фенил-11Н-индолизин [8,7-β] индол, лаппаконитин и цитизин в дозе 5 мг/кг по сравнению с крысами контрольной группы в условиях экспериментального эмоционального стресса, проявлялось анксиолитическое (противотревожное) действие.

**Ключевые слова:** *бета-карболин, тест принудительного плавания, виртуальный скрининг на основе докинга, нейротропная активность.*

## 1. INTRODUCTION:

Beta-carboline alkaloids show a wide range of psychopharmacological effects through binding to benzodiazepine, imidazoline, serotonin and opiate receptors, as well as monoamine oxidase (MAO) inhibition (Herraiz *et al.*, 2010; Liu *et al.*, 2017; Xiong *et al.*, 2018; Costanzi *et al.*, 2019). Neurochemical and behavioral studies have shown that some beta-carboline alkaloids facilitate dopaminergic transmission and interact with dopaminergic receptors D1 and D2 in the striatum (Farzin *et al.*, 2011; Li *et al.*, 2017; Ye *et*

*al.*, 2017; Liu *et al.*, 2019). Most beta-carboline alkaloids are known to be potent inhibitors that metabolize catecholamine neurotransmitters (Yonezawa *et al.*, 2011; Taborskaya *et al.*, 2017; Axen *et al.*, 2017; Moore *et al.*, 2018). Harmine, an indole alkaloid, shows antidepressant activity, interacting with MAO-A and several cell surface receptors, including serotonin 2A receptor (5-hydroxytryptamine receptor 2A, 5-HT2A) (Réus *et al.*, 2010; Nasehi *et al.*, 2018; Kwon *et al.*, 2018; Li *et al.*, 2018; Long *et al.*, 2019; Sun *et al.*, 2019).

The effects of harmine, norharmane, and guanine alkaloids on immobility time in the forced

swimming test (FST) in mice, a model of depression in animals, were studied. It was concluded that harmine, norharmane and guanine shorten immobility time in this test, suggesting an antidepressant effect, due to the inverse agonistic mechanism located in benzodiazepine receptors (Farzin and Mansouri, 2006; Dai *et al.*, 2018; Xi *et al.*, 2018). A forced swimming test (FST) and an elevated plus maze (EPM) were used to determine the antidepressant and anxiolytic effects of harmine in rats compared to a known antidepressant, imipramine (30 mg/kg ip). Administration of harmine resulted in a dose-dependent reduction of the immobility time in the FST and increased the time spent in the open arms in the EPM, compared to the group which received saline (dos Santos and Hallak, 2017; Herraiz and Guillén, 2018). Therefore, as an endogenous substance, it has anti-anxiety and anti-depressant effects (Arıcıoglu and Altunbas, 2003; Chen *et al.*, 2017; Wang *et al.*, 2018; Ferraz *et al.*, 2019).

Several potential molecular targets that have been identified for the central pharmacological effects of harmine include zinc-dependent kinases CDK (CDK1, 2 and 5), MAO-A, 5-HT<sub>2A</sub> sites, and imidazoline receptors I1 and I2. Harmine is a potent, double specific tyrosine phosphorylation inhibitor regulated by kinase (DYRK) (Song *et al.*, 2004; Egusa *et al.*, 2011; Ueda *et al.*, 2019). Harmine has been reported to show antidepressant effects in rodents (Réus *et al.*, 2012; Deng *et al.*, 2017; Zhang *et al.*, 2019). Harmine has anxiolytic, behavioral effects and antitumor potential both *in vitro* and *in vivo* (Hamsa and Kuttan, 2011; Cui *et al.*, 2019a). Harmine has a high inhibitory affinity to the kinase activity of DYRK1A, which indicates that harmine can modify tau phosphorylation (Frost *et al.*, 2011; Zhao *et al.*, 2019). Harmine also has a dual effect on the upstream potential of the atrial muscle (Carpentier, 1982). Also, a cytotoxic activity against human tumor cell lines has been reported in humans (Cao *et al.*, 2005; Freire *et al.*, 2018).

At the International Research and Production Holding "Phytochemistry" (Karaganda, Kazakhstan), a phytochemical study of an individual compound obtained from the roots of harmel peganum (*Peganum harmala* L.) growing in the southern regions of the Republic of Kazakhstan was carried out. Harmine, an indole alkaloid, was isolated and processed, and a water-soluble form, harmine hydrochloride, was synthesized. Studies of harmine hydrochloride pharmacological activity show edits potential antiparkinsonian activity (Turmukhambetov, 2009;

Turmukhambetov *et al.*, 2009). Further toxicological studies showed that harmine hydrochloride had no toxic effects on the internal organs or brain in a chronic three-month experiment in rats at the studied doses of 2.5 and 5 mg/kg (Lou *et al.*, 2017; Zhanaidarova *et al.*, 2019; Cui *et al.*, 2019b; Krüzselyi *et al.*, 2019).

The antiparkinsonian effects of harmine hydrochloride were studied in the experiments. To achieve this goal, the authors used haloperidol-induced catalepsy and MPTP-induced Parkinson's disease. It was found that harmine hydrochloride at a dose of 2.5 mg/kg eliminated haloperidol-induced catalepsy in rats and reduced hypokinesia and rigidity in the test for parkinsonism in C57BL/6 mice (Nurmaganbetov *et al.*, 2019). Based on the results, the search for new harmine derivatives with neuroprotective activity was continued.

The purpose of the study was to investigate the neuroprotective/stress-protective action of new derivatives of alkaloid compounds using the methods of computer simulation, docking-based virtual screening, and experimental pharmacology.

## 2. MATERIALS AND METHODS:

The following compounds were presented for the study: harmine N-oxide, 6-bromoharmine; 8-bromoharmine; 6,8-dibromoharmine; 6-iodoharmine; 6,8-dichloroharmine; 9-methoxy-2-phenyl-11*H*-indolisino[8,7- $\beta$ ]indole; 9-methoxy-2-(4-methoxyphenyl)-11*H*-indolisino[8,7- $\beta$ ]indole; 2-(3,4-dichlorophenyl)-9-methoxy-11*H*-indolisino[8,7- $\beta$ ]indole; 2-(4-methoxy-phenyl)-3,10-bis-formyl-11*H*-indolisino[8,7- $\beta$ ]indole; 3-acetyl-9-methoxy-2-phenyl-11*H*-indolisino[8,7- $\beta$ ]indole; 8-acetylharmine; 8-formylharmine; chalcone derivative of harmine; pyrazoline derivative of harmine; 4-methoxychalcone derivative of harmine; 4-methoxy-pyrazoline derivative of harmine; 2,4-dimethoxy-chalcone derivative of harmine; 2,4-dimethoxy-pyrazoline derivative of harmine; 2,3,4-trimethoxy-chalcone derivative of harmine; 2,3,4-trimethoxy-pyrazoline derivative of harmine; 2-F-chalcone derivative of harmine; 2-F-pyrazoline derivative of harmine.

Computer modeling of the molecules of alkaloid derivatives and docking-based virtual screening with an estimated biological target, DRD2 receptor, one of the five known types of dopamine receptors belonging to the class of D<sub>2</sub>-like receptors which inhibit adenylate cyclase, were performed (Arıcıoglu and Altunbas, 2003). Three-dimensional models of the ligand molecules were constructed using the ChemDraw program,

using a set of programs Autodock (The Scripps Research Institute, USA), MGLTools (The Scripps Research Institute, USA). The binding energy of an individual conformation was used as a final result, which shows the strength of the interaction between the ligand and the target molecule.

The experimental part was carried out following the "Rules of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes" (European Convention..., 1986) and under the requirements for the studies of new pharmacological substances in sexually mature rats (60 animals), equal amounts of females and males, with initial body weight of 240-370 g. The animals were kept in standard vivarium conditions on a regular diet and free access to water and food. Besides, general conditions of the animals were evaluated: changes in the animal's body weight, motor activity, appetite and reaction to external stimuli.

Emotional stress was modeled by placing the rats in tight plastic cylinders with their subsequent immersion in water to the neck level (20-22°C) for 2 hours daily for four days (Razueva *et al.*, 2014). The studied substances were administered to the animals at doses of 5 mg/kg for seven days before modeling emotional stress followed by a daily administration 1 hour before placing the animals in the plastic cylinders. Piracetam (JSC "BZMP", Republic of Belarus) was used as a reference drug, which was administered to the animals according to a similar scheme. All drugs were administered daily orally in the form of an aqueous solution at a dose of 1 ml/kg. The animals of the control and intact groups received purified water in the same volume.

On the fourth day after emotional stress modeling, the behavioral effects of the studied compounds were assessed using generally accepted methods in the following tests: "Open Field" and "Elevated Plus Maze" (Koplik *et al.*, 1995). Statistical processing of the results was carried out using the "Statistica 8.0" software package. The results are presented as "mean values  $\pm$  standard error of the mean". The differences were considered significant at a significance level of  $p < 0.05$ .

### 3. RESULTS AND DISCUSSION:

According to the docking results, the presented molecules of alkaloid compounds showed interactions with dopamine receptor D2. According to the docking results, the following alkaloid derivatives showed the maximum binding

to dopamine receptor D2: 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole (BE = -11.6); 2-(3,4-dichlorophenyl)-9-methoxy-11H-indolisino[8,7- $\beta$ ]indole (BE = -10.7); 2-F-chalcone derivative of harmine (BE = -10.7) (Table 1). The spatial structures of the ligands and a schematic representation of the ligand-target interactions are presented in Figures 1-3.

During the experiment to assess an *in vivo* neurotrophic activity, it was noted that body weight data in the rats from all groups remained within baseline parameters; there were no significant changes in body weight gain in the animals from all groups (Table 2).

Administration of the studied compounds, harmine, 8-acetylharminine, delcosine and lappaconitine, to rats reduced the number of entries into the closed arms; administration of 8-acetylharminine and lappaconitine increased the number of peeps. The number of leaning overincreased in the 8-acetylharminine and delcosine groups. The number of defecations and urinations decreased in the groups of 8-acetylharminine, ((E)-1-(7-methoxy-1-methyl-9H-pyrido[3,4-b]indole-8-yl)-3-(2,4-dimethoxyphenyl)prop-2-en-1-on, (E)-1-(7-methoxy-1-methyl-9H-pyrido[3,4-b]indole-8-yl)-3-(2-fluorophenyl)prop-2-en-1-on and echinopsine (Tables 3, 4).

According to the docking results, the following alkaloid derivatives showed the maximum binding to dopamine receptor D2: 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole (BE = -11.6); 2-(3,4-dichlorophenyl)-9-methoxy-11H-indolisino[8,7- $\beta$ ]indole (BE = -10.7); 2-F-chalcone derivative of harmine (BE = -10.7). This experimental study showed that indole alkaloids, 8-acetylharminine, 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole, diterpene alkaloid lappaconitine and cytosine at a dose of 5 mg/kg exhibit neurotropic effects, increase the levels of orientation and research activity, normalize emotional state and decrease anxiety and fear levels in animals.

### 4. CONCLUSIONS:

The results obtained in the "Elevated Plus Maze" test showed that the animals treated with 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole, lappaconitine and cytosine at a dose of 5 mg/kg, compared to rats in the control group, experienced an anxiolytic (anti-anxiety) action in the experimental emotional stress.

In particular, the time spent in the closed

arms was reduced by 23.9% in the lappaconitine group, by 12.5% in the 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole group, by 12.4% in the 8-acetylgermine group and by 5.6% in the cytosine group, compared to the control group. The time spent by the animals in the open arms increased by 78% in the 9-Methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole group, by 76.4% in the lappaconitine group, by 76.1% in the 8-acetylgermine group and by 64.1% in the cytosine group, compared to the control group. The time spent on the central site increased by 37.8% in the lappaconitine group, compared to the control group.

Therefore, 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole, which had the highest binding energy during ligand-target docking, is a candidate substance as a stress-protective agent for further in-depth studies, as well as indole alkaloids, 8-acetylgermine, 9-methoxy-2-phenyl-11H-indolisino[8,7- $\beta$ ]indole, and diterpene alkaloid lappaconitine, which showed an anxiolytic effect in the stress test.

### RESUMO

O nitrato de amônio é o fertilizante de nitrogênio mais comum e eficaz do mundo. No entanto, o nitrato de amônio tem uma desvantagem muito séria – o risco de incêndio e o risco de explosão, o que causa certas dificuldades e limitações tanto para seus consumidores quanto para seus fabricantes. O objetivo deste trabalho foi estudar a possibilidade de produzir os fertilizantes NPK com propriedades agroquímicas melhoradas e com uma proporção controlada de nutrientes N/P<sub>2</sub>O<sub>5</sub>/K<sub>2</sub>O, obtidos com base em uma solução de nitrato de amônio, rocha fosfática moída e cloreto de potássio. Os experimentos laboratoriais e industriais foram realizados usando um método de planejamento rotativo – o método de modelagem de segunda ordem Box-Hunter. O artigo apresenta os resultados de estudos sobre a regulação da proporção de nutrientes (N/(P<sub>2</sub>O<sub>5</sub> + K<sub>2</sub>O)) em fertilizantes contendo NPK, obtidos com base em uma solução de nitrato de amônio, rocha fosfática moída e cloreto de potássio. Foi estudada a influência de variáveis independentes – consumo específico de nitrato de amônio, fósforo moído e cloreto de potássio. Foi obtida uma equação de regressão adequada da influência desses fatores na proporção N/(P<sub>2</sub>O<sub>5</sub> + K<sub>2</sub>O) nos produtos finais. Os valores-limite do consumo específico de nitrato de amônio, fósforo moído e cloreto de potássio nas misturas iniciais foram encontrados, nos quais o conteúdo total de nutrientes nos produtos-alvo é de 30% a 33%, e o coeficiente N/(P<sub>2</sub>O<sub>5</sub> + K<sub>2</sub>O) possui um valor ótimo (1,14 - 3,50).

**Palavras-chave:** *nitrato de amônio, farinha fosfórica, cloreto de potássio, nutrientes, composição química.*

### ABSTRACT

Ammoniac saltpeter is the most widespread in the world and effective nitric fertilizer. However, ammonia saltpeter has a severe disadvantage – fire risk and explosion hazard that causes some difficulties and restrictions of both its consumers and its manufacturers. The purpose of the present work consisted in the studying the possibility of production of NPK-fertilizers with improved agrochemical properties and a controlled ratio of nutrients N/P<sub>2</sub>O<sub>5</sub>/K<sub>2</sub>O produced based on an ammonia saltpeter solution, ground phosphate rock, and potassium chloride. The laboratory and industrial experiments were continued using a rotatable planning method – the Box-Hunter second-order modeling technique. The article contains the research results on the regulation of nutritious elements (N/(P<sub>2</sub>O<sub>5</sub>+K<sub>2</sub>O)) ratios in the NPK-containing fertilizers produced based on an ammonia saltpeter solution, a ground phosphate rock, and potassium chloride. The effect of independent variables – specific consumptions of ammonia saltpeter, a ground phosphate rock, and potassium chloride – was studied. The adequate regression equation of influence of these factors on an N/(P<sub>2</sub>O<sub>5</sub>+K<sub>2</sub>O) ratio in the end products was obtained. Boundary values of the ammonia saltpeter, a ground phosphate rock and potassium chloride specific consumptions in the initial mixtures were found at which the total content of nutritious elements in the target products is from 30% to 33% and the N/(P<sub>2</sub>O<sub>5</sub>+K<sub>2</sub>O) ratio has the optimum value (1.14 - 3.50).

**Keywords:** *ammonium nitrate, phosphorus flour, potassium chloride, nutrients, chemical composition.*

### АННОТАЦИЯ

Аммиачная селитра является наиболее распространенным в мире и эффективным азотным

удобрением. Однако аммиачная селитра имеет очень серьезный недостаток – риск возникновения пожара и опасность взрыва, что вызывает определенные трудности и ограничения как у ее потребителей, так и у ее производителей. Цель настоящей работы состояла в изучении возможности получения NPK-удобрений с улучшенными агрохимическими свойствами и контролируемым соотношением питательных веществ  $N/P_2O_5/K_2O$ , получаемых на основе раствора аммиачной селитры, измельченной фосфоритовой породы и хлорида калия. Лабораторные и промышленные эксперименты были проведены с использованием вращающегося метода планирования – метода моделирования второго порядка Box-Hunter. В статье приведены результаты исследований по регулированию соотношений питательных элементов ( $N/(P_2O_5 + K_2O)$ ) в NPK-содержащих удобрениях, полученных на основе раствора аммиачной селитры, измельченной фосфатной породы и хлорида калия. Было изучено влияние независимых переменных – удельного расхода аммиачной селитры, молотого фосфорита и хлорида калия. Получено адекватное регрессионное уравнение влияния этих факторов на отношение  $N/(P_2O_5 + K_2O)$  в конечных продуктах. Найдены граничные значения удельных расходов аммиачной селитры, молотого фосфорита и хлорида калия в исходных смесях, при которых общее содержание питательных элементов в целевых продуктах составляет от 30% до 33%, а  $N/(P_2O_5 + K_2O)$  коэффициент имеет оптимальное значение (1,14 - 3,50).

**Ключевые слова:** аммиачная селитра, фосфорная мука, хлорид калия, питательные вещества, химический состав.

## 1. INTRODUCTION:

Ammoniac saltpeter is the most widespread in the world and effective nitric fertilizer (Ivanov *et al.*, 1990; Chernyshev *et al.*, 2009). It is used in agriculture for all kinds of crops and any types of soils (Maltas *et al.*, 2018; Besterekov *et al.*, 2019). However, ammonia saltpeter has a severe disadvantage – fire risk and explosion hazard that causes some difficulties and restrictions of both its consumers and its manufacturers (Oxley *et al.*, 2002; Dechy *et al.*, 2004; Lavrov and Shedov, 2004; Sinditskii *et al.*, 2005). For this reason, to obtain rich and qualitative harvests, it is necessary to apply balanced mineral fertilizers, i.e., containing nitrogen, phosphorus, potassium and other nutrients in reasonable ratios (Skydanenko *et al.*, 2017; Daitx *et al.*, 2019; Ramadhani *et al.*, 2019). These are so-called complex fertilizers whose major characteristic is their high agrochemical value (Abramov *et al.*, 2002; Levin and Sokolov, 2004; Pavlova, 2007; Ovchinnikov *et al.*, 2008; Akhmad *et al.*, 2018).

At present, there is a great demand for the fertilizers containing nitrogen, phosphorus and potassium that promotes numerous researches on introduction of phosphorus and potassium-containing components, be it natural minerals, the products obtained at their industrial processing or technogenic phosphorus and potassium-containing waste, in ammonia saltpeter melt (Belova and Ryabtseva, 2007; Dmitrieva and Ovchinnikov, 2007; Botirov and Beglov, 2008; Kiiski, 2009; Reymov *et al.*, 2013; Taran and Taran, 2016; Tugalukov *et al.*, 2017; Zhang *et al.*, 2018; Hirzel *et al.*, 2019; Yan *et al.*, 2019).

The only manufacturer of ammonia

saltpeter in the Republic of Kazakhstan is “KazAzot” JSC (Aktau, Kazakhstan). To solve the above-mentioned problem on the improvement of ammonia saltpeter agrochemical value and consumer properties, the own phosphate ores of the Republic of Kazakhstan can be successfully applied (Directory of deposits..., 2014). According to a draft proposal of the “KazAzot” JSC concerning to determination of new possibilities of improvement of agrochemical and consumer properties of ammonia saltpeter, the scientific personnel of the chair “Chemical technology of inorganic substances” of M. Auezov South Kazakhstan State University (Shymkent, Kazakhstan) (Official site..., 2019) has implemented the research on production of new NPK fertilizers on the basis of the following initial components: the ammonia saltpeter solution produced by “KazAzot” JSC, State Standard 2-2013; the ground phosphate rock of FM-2 grade (TS 930640000252-01-2011, 17% of  $P_2O_5$ ), produced by “Temir-service” LP (Aktyubinsk, Kazakhstan) from the Chilisay phosphorite (The mining company..., 2014); potassium chloride – the most available potassium salt – meeting to technical requirements 2184-048-00203944-2014. Under the agreement with the customer, the 64-71 % ammonia saltpeter solution obtained in accordance with the traditional ammonia saltpeter technology at the first evaporation stage was applied as the initial component. The agreed content of nitrogen, phosphorus pentoxide and potassium oxide in the end products were 10-28%, 2.5-10%, and 2.5-10%, respectively.

The purpose of the present work consisted in the studying the possibility of production of NPK-fertilizers with improved agrochemical properties and a controlled ratio of nutrients  $N/P_2O_5/K_2O$  produced based on an ammonia saltpeter

solution, ground phosphate rock and potassium chloride.

## 2. MATERIALS AND METHODS:

The research was carried out under the laboratory conditions of M. Auezov SKSU. The experimental results were tested at a trial plot of the operating ammonia saltpeter manufacture of "KazAzot" JSC. During the experiments, the individual volumes of 64-71% ammonia saltpeter solution with temperature of 110-130°C were mixed with calculated weights of the ground phosphate rock and potassium chloride (Dier *et al.*, 2018; Galliou *et al.*, 2018; Sigurnjak *et al.*, 2019). Insignificant quantities of a modifying mineral additive were also added in the mixture. The obtained suspension was carefully agitated and fed at the temperature of 120-130°C in sprayers of a granulating drum where the mixture was sprayed and dried by a direct-flow drying agent and granulated at the observance of technological parameters of the operating ammonia saltpeter manufacture (Ivanov *et al.*, 1990; Technological regulations..., 2012; Artyukhov and Ivaniia, 2017; Boyandin *et al.*, 2017; Gorbovskiy *et al.*, 2017; Lombardo *et al.*, 2017; Churov *et al.*, 2018; Rus *et al.*, 2019).

The analysis of composition and properties of the initial components and the obtained NPK-fertilizer samples was implemented according to the methods given in the standard documentation on the fertilizers:

- the total nitrogen content in the obtained NPK fertilizer according to State Standard 30181;
- the total and assimilable phosphorus pentoxide content ( $P_2O_5$ total,  $P_2O_5$ assim.) – in accordance with State Standard 20851.2-75;
- the potassium chloride mass fraction – in accordance with State Standard 20851;
- moisture content – in accordance with State Standard 20851.4;
- strength of the fertilizer granules on a device IPG-1M;
- pH on a device I-160 MI (Raposo *et al.*, 2017; Gezerman and Çorbacioğlu, 2017; Bamatov *et al.*, 2019; Macholdt *et al.*, 2019).

## 3. RESULTS AND DISCUSSION:

Tables 1 and 2 contain the results of the experimental research carried out at the laboratory and industrial conditions. Specific consumptions of the ammonia saltpeter, ground phosphate rock,

and potassium chloride were calculated in terms of 1 tonne of the target product.

First of all, the influence of specific consumptions of ammonia saltpeter, ground phosphate rock and potassium chloride, and also content of nutritious elements in them on the ratio of  $N/(P_2O_5+K_2O)$  in the target products was studied. The results of the research are represented in Figures 1-3.

As follows from the obtained results, the change of the  $N/(P_2O_5+K_2O)$  ratio in the products depends on two opposite processes: its growth at the increase in the nitrogen content, i.e. the specific ammonia saltpeter consumption, and its decrease at the increase in the phosphorus and potassium content, i.e., specific consumptions of the phosphorite and potassium chloride. In this connection, the further research was performed using a rotatable second-order experiment's planning technique (the Box-Hunter method) (Akhazarova and Kafarov, 1985; Zečević *et al.*, 2017; Silver *et al.*, 2018; Jameel and Al-Tai, 2017; Bijarniya *et al.*, 2019). The ratio of  $N/(P_2O_5+K_2O)$  in the product was the optimization parameter. Table 3 contains the information about domains of variation of the independent variables calculated based on data of Table 1. The experiments' planning matrix and results are represented in Table 4.

Using the data of Table 4 and (Inkov *et al.*, 2000) we obtained the regression equations of influence of ammonia saltpeter, phosphorite and potassium chloride amounts in the initial mixture on the  $N/(P_2O_5+K_2O)$  ratios in the coded and natural kinds (Equations. 1-2):

Determination of the coefficients in regression equation (2) was carried out using the Student's test, and the adequacy of the equation – using the Fisher's test. In our case, the Fisher's test tabular value makes 5.10, and its calculated value taking into account a 5% error of the experiment is 5.00. As  $F_{tab} > F_{cal}$ , the obtained regression equation is adequate. The experimental and calculated according to (2) values of  $N/(P_2O_5+K_2O)$  ratios in the NPK fertilizers produced are represented in Table 5.

On the basis of equation (2) using the MathCAD program (Ochkov, 2007) the 3D images of response surfaces of  $N/(P_2O_5+K_2O)_{nat} = f(AS, GPR \text{ at } KCl = \text{const} = 0.097; 0.063; 0.131; 0.154; 0.352 \text{ (according to data of Table 4)})$  and their horizontal sections were constructed (Figures 4-8).

Besides the  $N/(P_2O_5+K_2O)$  ratio, modern

fertilizers should meet the following requirements: the size of fertilizer's granules – 2-4 mm, their mass fraction – not less than 83-89%, the granules' strength – not more than 60 N/g. As follows from Table 2 data, these requirements are fulfilled if the  $N/(P_2O_5+K_2O)$  ratio  $\geq 1.14$ . Figures 1-5 show the areas *mnpj*, *xyzh*, *abcd*, *qwvf*, *rusk*, for which this ratio is 1,14-3.50.

Table 6 contains the information about the boundary values of optimization parameters and variable factors for  $N/(P_2O_5+K_2O) \geq 1.14$ .

As follows from Figures 1-5 and table 6, the least value of the optimization parameter – the  $N/(P_2O_5+K_2O)$  ratio – is characteristic for the technological area *rusk*. Therefore, the optimization of the process studied should be carried out within the *rusk* area. The values of technological parameters in the *rusk* area are represented in Table 7.

Judging by the data of Figure 5 and Table 7, the optimum values of ammonia saltpeter and ground phosphate rock specific consumptions at the maximum allowed particular potassium consumption chloride equal to 0.154 t and the  $N/(P_2O_5 + K_2O)$  ratio in the NPK-fertilizer obtained within 1.14-1.73 are situated on lines *ks* (ammonia saltpeter) and *su* (phosphorite). That is the specific consumption of ammonia saltpeter can change from 0.47 t to 0.71 t, and for the phosphorite – from 0.23 t to 0.47 t.

#### 4. CONCLUSIONS:

Based on the results obtained at the modeling the influence of ammonia saltpeter, ground phosphate rock and potassium chloride specific consumptions on the nutrients ( $N/(P_2O_5 + K_2O)$ ) ratio in the NPK-containing products it is possible to draw the following conclusions:

- the change of the  $N/(P_2O_5+K_2O)$  ratio in the target products depends on two opposite processes: its growth at the increase in the nitrogen content, i.e., the specific ammonia saltpeter consumption, and its decrease at the increase in the phosphorus and potassium content, i.e., specific consumptions of the phosphorite and potassium chloride;

- to produce the NPK-containing fertilizers of required quality and with the  $N/(P_2O_5 + K_2O)$  ratio within 1.14-3.50 based on the 64-71% ammonia saltpeter solution (State Standard 2-2013), the Chilisay ground phosphate rock of FM-2 grade (TS 930640000252-01-2011, 17% of  $P_2O_5$ ) and potassium chloride meeting to technical requirements 2184-048-00203944-2014, the

consumptions of the components should be maintained in the following limits: ammonia saltpeter – 0.4-0.71 t, Chilisay ground phosphate rock – 0.23-0.47 t, potassium chloride – 0.040-0.131 t. At the maximum allowed potassium chloride rate (0.154 t), the corresponding consumptions of ammonia saltpeter and Chilisay phosphorite are in the limits of 0.47-0.71 t and 0.23-0.47 t, respectively. In this case, it is possible to produce many nitrogen, phosphorus, and potassium-containing fertilizers in which the total content of nutritious elements will make: 33%; 32%; 31%; 30%; that convincingly enough prove their high agrochemical value.

#### 5. ACKNOWLEDGMENTS:

The authors are grateful to the management of the "KazAzot" JSC for the material, technical, and financial support of the research.

## RESUMO

Um método bem conhecido, acessível e barato de modificação de biopolímeros é simplesmente sua mistura com polímeros sintéticos e naturais. Como resultado, semelhante às ligas metálicas, é possível obter complexo interpolímeros com propriedades predeterminadas. Apesar do fato de que os complexos interpolímeros terem sido estudados e aplicados há muito tempo, na prática doméstica o estudo de biopolímeros naturais é limitado. O objetivo deste estudo é apresentar e estudar o problema de estruturação em soluções de biopolímeros e polímeros sintéticos, uma vez que, com baixo teor de matéria seca, essas estruturas têm muitas propriedades do corpo sólido. Polímeros anfóliticos naturais são polieletrólitos, o que também é de grande importância para estudos futuros. Ao analisar os resultados de estudos de complexos formados por um polieletrólito linear sintético com o parceiro carregado – a proteína, torna-se possível criar novos complexos de polieletrólitos “inteligentes” que podem sofrer alterações de fase em faixas estreitas e controladas de pH. Foi estabelecido o efeito positivo da carboximetilcelulose de sódio na gelificação de hidrogéis de gelatina a 5%. Foi estabelecido que a presença de aditivos de sais inorgânicos leva a um aumento na expansão de géis de gelatina. Foi também estabelecido que os géis mais duráveis são menos propensas ao envelhecimento. A importância prática desses estudos é determinada pelo fato de que em várias indústrias de alimentos, sabão, tinta e verniz e outras, é necessário obter estruturas com as propriedades desejadas. A formação dos géis também pode ser um fenômeno indesejável que deve ser evitado, por exemplo, na produção de fibras químicas, colas e soluções de bronzeamento. Além disso, na maioria dos casos, os próprios objetos biológicos são os géis de proteínas com certas propriedades mecânicas.

**Palavras-chave:** *estrutura e dinâmica de gel de gelatina, gelificação de gelatina, colapso de redes heterogêneas, expansão de gel de gelatina, adsorção de gelatina.*

## ABSTRACT

A well-known, affordable, and cheap method of modifying biopolymers is their simple mixing with synthetic and natural polymers. As a result, similar to metal alloys, polymer-polymer complexes with predetermined properties can be obtained. Although interpolymers complexes became a subject of study and application a long time ago, in domestic practice, the study of natural biopolymers is limited. The purpose of this study was to present and study the issue of structuring in solutions of bio- and synthetic polymers, as with a low dry matter content such structures have many properties of a solid. Natural ampholytic polymers are polyelectrolytes, which is also of great importance for their further study. By analyzing the results of studies of complexes formed by a synthetic linear polyelectrolyte with a charged partner – protein, it becomes possible to create new “smart” polyelectrolyte complexes that can undergo phase changes in narrow, controlled pH ranges. The positive effect of sodium carboxymethyl cellulose on the gelation of 5% gelatine hydrogels was established. It was determined that the presence of additives of inorganic salts leads to an increase in the swelling of gelatine gels. It was established

that more durable gels are less prone to aging. The practical significance of these studies is determined by the fact that in many industries (food, soap, paint, and varnish), it is necessary to obtain structures with tailor-made properties. Gel formation may also be an undesirable phenomenon that must be prevented, for example, in the production of chemical fibers, glues, and tanning solutions. Furthermore, biological objects themselves in most cases, by their nature, are protein gels with specific mechanical properties.

**Keywords:** *structure and dynamics of gelatine mixed hydrogels, adsorption on solid surfaces, collapse of heterogeneous networks, swelling and aging of mixed gelatine hydrogels.*

## АННОТАЦИЯ

Хорошо известным, доступным и дешевым методом модификации биополимеров является их простое смешение с синтетическими и природными полимерами. В результате, подобно сплавам металлам, можно получить полимер-полимерные комплексы с заранее заданными свойствами. Несмотря на то, что интерполимерные комплексы начали изучаться и применяться давно, в отечественной практике изучение природных биополимеров ограничено. Цель данного исследования – представить и изучить проблему структурирования в растворах био- и синтетических полимеров, так как при незначительном содержании сухого вещества такие структуры обладают многими свойствами твердого тела. Природные амфолитные полимеры являются полиэлектролитами, что также имеет огромное значение для их дальнейшего изучения. Анализируя результаты исследований комплексов, образованных синтетическим линейным полиэлектролитом с заряженным партнером – белком, становится возможным создание новых «умных» полиэлектролитных комплексов, способных претерпевать фазовые изменения в узких, контролируемых диапазонах pH. Установлено положительное влияние натрийкарбоксиметилцеллюлозы на гелеобразование 5% гидрогелей желатина. Установлено, что присутствие добавок неорганических солей приводит к увеличению набухания студней желатина. Установлено, что более прочные студни менее подвержены старению. Практическое значение этих исследований определяется, тем, что в ряде отраслей промышленности пищевой, мыловаренной, лакокрасочной и других надо получать структуры с заданными свойствами. Образование студней может оказаться и нежелательным явлением, которое надо предотвращать, например, в производстве химических волокон, клеев, растворов дубителей и т.д. Кроме того, сами биологические объекты в большинстве случаев по своей природе представляют собой студни белков с определенными механическими свойствами.

**Ключевые слова:** *структура и динамика смешанных желатиновых гидрогелей, адсорбция на твердых поверхностях, коллапс гетерогенных сеток, набухание и старение смешанных желатиновых гидрогелей.*

## 1. INTRODUCTION:

The possibility of a directed change in the properties of biopolymers due to external influences, such as the formation of stable association products with macromolecules and low molecular weight compounds (alcohols, carbohydrates, salts, etc.), makes them one of the most promising materials. In addition, another relevant study is of the effect of the interaction of the mixture components on the rheological and conformational properties of macromolecules due to non-covalent polymer interactions. The study of interpolymer complexes based on natural biopolymers is necessary for the further development of the technology for the production of environmentally friendly products that are promising for agriculture, medicine, food industry, cosmetology, etc. (Lanik, 1986; Tsereteli and Smirnova, 1991; Irshak and Varyukhin, 1995; Shandryuk *et al.*, 2002).

Feature of the formed biopolymer systems

is the mechanical properties of the resulting interpolymer complexes, allowing their use in technical industries. For example, mixed systems of polysaccharide-based biopolymers are used in the oil industry as reagents as drilling agents and flushing fluids. It is proved that the inclusion of small amounts of mixed systems based on gelatine and polyvinyl alcohol, sodium caseinate and polyvinyl alcohol in the feed composition increases the biological value of feed and increases the productivity of animal and poultry product, which makes it promising to apply mixed systems based on natural polymers in animal husbandry (Izmailova *et al.*, 1964; Pchelin, 1972; Vasiliev, 1981).

The mechanism and laws of formation, deformation, and destruction of dispersed structures of various types from liquid-like to high-strength materials of modern technology are the subject of the physicochemical mechanics of dispersed systems. From literature data (Gurevich, 1975; Busk, 1984; Deryagin, 1990; Katsuyoshi, 1993) it is known that an important

condition for the formation of a gel is the lack of the ability of the polymer to dissolve in a solvent unlimitedly. This condition, reduction of the interaction of the polymer and the solvent, can be achieved by changing the temperature, the nature of the solvent, the introduction of precipitators, specific additives. The fact that the loss of solubility does not lead to demixing is connected with the fact that the polymer chain molecules bind in solution during gelation into a single spatial structure that covers the entire volume.

An essential condition for gelation is the achievement of a specific, so-called critical concentration of the solution. Gelation can also occur when certain additives are introduced into polymer solutions, which lead to the formation of intermolecular or chemical bonds between different polymer macromolecules (Karásek and Meissner, 1992). The gelation process is also affected by the structure of the macromolecule itself. Gel formation also depends on the flexibility of the polymer chain and its conformation in solution (Yiebke *et al.*, 1994). Some ordering in the arrangement of polymer molecules is necessary for the emergence of secondary structures. However, with a large ordering of polymer macromolecules relative to each other, a precipitate forms. It should be noted that the gel state is the usual state of natural substances. Gels of various nature arouse the interest of researchers due to the emergence of the frame, which determines the mechanical properties of gels in the structure (Irshak and Varyukhin, 1995).

By definition of S.P. Papkov (1971), the gel phase is a matrix in which the second, low-concentrated polymer equilibrium phase is located. Such structures are characterized by the practical absence of irreversible deformation of the gel as a whole. Studying the rheological properties of jellies and their dependence on the type of stresses, temperature, duration of various influences, including the composition of the components allows to indirectly judge on the structure of gels, in particular, on their affiliation to a certain type (Valevsky, 1983; Hidekazu and Yoshihito, 1993; Kuleznev, 1993).

The purpose of this study was to present and study the issue of structuring in solutions of bio- and synthetic polymers, as with a low dry matter content such structures have many properties of a solid.

## 2. LITERATURE REVIEW:

In recent years, the principle of molecular recognition, which is based on steric effects,

electrostatic interaction, and hydrogen bonding, has been widely used in organic and polymer chemistry as a way to create new supramolecular materials. In the work of Shandryuk (Shandryuk *et al.*, 2002), a directed modification of systems is performed by introducing additives capable of hydrogen bonding with a polymer matrix. Rheological studies demonstrated that liquid crystal hydrogen-bonded networks are capable of large reversible deformations (up to 4-5-fold degrees of extension). Relatively many works are devoted to gelation of aqueous gelatine solutions. Most of these works are collected in Veys' monograph (Veys, 1971). It follows that the minimum concentration of gelatine gel formation is 0.5% and does not depend on pH in the region of 4-8 at temperatures below 18°C; at temperatures above 25°C, the gelation concentration increases and becomes dependent on the pH of the medium: in the region  $\text{pH} = 4.6 \div 4.8$  and at a temperature of 0°C 0.6% gelatine solution does not gelate for 20 hours.

Gelatine gels were repeatedly subjected to structural and mechanical studies due to having solid-like properties. However, there are very conflicting ideas in the matter of the structure of gelatine gels. In particular, the fact that gelatine gels belong to two- or single-phase gels causes controversy and doubts among researchers. Two possible assumptions are made regarding the cause of gelation of gelatine solutions after the conformational transition of its molecules from a coil to a spiral. The first is that there is a mechanism of local crystallization of spiralized macromolecules upon the formation of gel of the first type. According to the second hypothesis, due to the transition of gelatine to a rigid conformation, the polymer loses its solubility and forms a gel. In his work, A. Veys points out the unlikelihood of the gelation mechanism based on the renaturation of the structure of tropocollagen. Research conducted by G.I. Tsereteli and O.I. Smirnova (Tsereteli and Smirnova, 1991) points at the formation of metastable collagen-like structures in the process of gelation.

In his work, V.G. Vasiliev, having studied the effect of chemical crosslinking on the elastic modulus, concluded that a substantial increase does not occur in the latter. Crosslinking fixes the glomerular conformation of macromolecules, which prevents the formation of intermolecular bonds and, consequently, structure formation (Vasiliev, 1981). A series of works is devoted to the study of the rheological properties of gelatine solutions and jellies of various concentrations in a narrow temperature range and the replacement of

water with organic solvents (Rogovina *et al.*, 1971; Grigoryeva, 1975; Lanik, 1986). The properties of gelatine-water gels were experimentally studied at various temperatures, gelatine concentrations and frequencies of mechanical stresses. The relationship between the properties of gels and the shape and structure of polymer molecules was evaluated (Ross-Murphy, 1992; Hsu and Jamilison, 1993; Golfen and Borhard, 1994; Bocchard, 1998). An increase in high elasticity is also observed due to a possible change in both the nature of the bond in the spatial network and the conformations of macromolecules and a significant dependence of the elastic modulus of gelatine on the nature of the solvent. Authors believe that the Ferry-Eldridge equation is applicable to the researched systems with sufficient accuracy.

The study of the structure and dynamics of gelatine gels during temperature jumps by method of holographic relaxation spectroscopy was considered by Chi and Wolfgang (Chi and Wolfgang, 1990). The authors determined that in the process of normal cooling at a speed of 2 K/min two types of grids are formed. One type refers to a coarse structure formed by aggregation of collagen-like triplet standard helices, and the other – to a fine structure formed by links between gelatine molecules. Some works are devoted to the study of gelatine gels near the gelation threshold and in the immediate vicinity of the sol-gel transition point (Takahiro and Masayuki, 1990).

The published data on the thermal effect of gelation of gelatine are contradictory. Thus, having examined the sol-gel similarly to glass-liquid, absence of phase transition upon gelation is indicated (Nikolaev and Neumann, 1957). In contrast, other authors demonstrated that gelation of gelatine solutions is similar to crystallization and is accompanied by a thermal effect (Bobrova *et al.*, 1970; Gordovsky, 1971).

Many works cover the research of swelling and collapse of heterogeneous networks, including gelatine gels in an aqueous medium, as one of the characteristics of the void ratio of the formed structures. Patlazhan's (2002) work displayed that when polymer networks swell with an inhomogeneous crosslinking distribution, local internal stresses arise, the magnitude of which depends on the degree of swelling, the type and structure of the network. The effective swelling coefficient of such networks is less than the corresponding average value. Its relative change, including the statistical properties of internal stresses, are determined by the structural features

of the network, expressed through the correlation function of fluctuations of macromolecular chains connecting the neighboring nodes. The dependence of light scattering on the degree of swelling is investigated. It is concluded: with increasing degree of swelling, the scattering intensity passes through a maximum.

In the work of (Xion and Zheng Pei, 1997), research on the change in the volume of gelatine gels depending on the pH and ionic strength of aqueous solutions was conducted. The dependence of the swelling gel force (the force exerting pressure on the polymer network when it is enclosed in a cell of constant volume) is noted on these factors. The influence of changes in the volume of gels and swelling forces on chemomechanical energy, including on changes in rheological properties, is pointed out. V.V. Klepko and co-workers studied the kinetics and equilibrium of swelling of gelatine gels in a good solvent (Klepko and Melnichenko, 1994). It was demonstrated that in the studied range of ripening times (1÷5) hours, sol-gel transition temperatures (4÷22)°C and gelatine concentration in the initial solution (0.02÷0.13), the equilibrium degree of swelling depends on the initial concentration gel as  $F_0 - 0.4$ , which corresponds to Flory's theory.

Proceeding from the consideration of swelling as a diffusion-controlled process, it was concluded that the use of first-order kinetics is valid only at the initial and middle stages of the swelling process. At the stage of extensive swelling, first-order kinetics is not applicable. The explanation for this observation was made on the basis of the assumptions that the swelling rate is directly proportional to the relative swelling in time  $\tau$  and the specific area  $S_{int}$ , which limits the places of the polymer network that have not yet reacted with water in time  $\tau$ , but will be hydrated (Hans, 1992). The use of a new interferometric sensor and a special interferometer allowed the authors of the work (Chi and Chui-Sing, 1994) to study the kinetics of swelling of thin gelatine films. In situ measurements were performed both at times of several minutes and several days. It is noted that the data on swelling are well-suited for the kinetics of the first-order reaction, which contradicts the previous work. The discrepancies were explained by the significant difference in the processes in the solvent and in air, including the specificity of gelatine gels. The presence of a correlation between the shear modulus, the longitudinal modulus of elasticity, and the cooperative diffusion coefficient is noted.

The subject of the study is also the nature

of the bonds responsible for gelatine gelation. Some data give preference to nonpolar groups; according to other data, hydrogen and hydrophobic bonds play an important part in gelatine gelation (Izmailova *et al.*, 1964; Pchelin, 1972). The study of the interaction between water-soluble polymers, in particular proteins and surfactants, is necessary in connection with the expanding use of such joint systems in a number of biological and industrial processes. The work (Fruhner and Kzetzschmar, 1989; Roe *et al.*, 1998) researches the interaction between gelatine and ionic surfactant-alkyl sulfates and alkyl trimethylammonium ions by the direct method of surface-active selective electrolysis with a liquid membrane of o-nitrotoluene containing a complex of cetyltrimethylammonium dodecyl. The interaction of polyphenols with gelatine amino acids was studied in (Shi *et al.*, 1994). It was demonstrated that such an interaction is largely determined by hydrophobic forces.

In connection with the widespread use of gelatine in the pharmaceutical and food industries, adsorption of this fibrillar protein on solid adsorbents is being studied. The general regularities of the kinetics of gelatine adsorption at the solid-liquid border are discussed in (Bajpai, 1994). In (Bajpai, 1995), kinematic measurements of gelatine adsorption on alumina were performed. To analyse the adsorption process and its kinetic parameters, the magnetic formalism technique was used. The effect of gelatine pH, salt concentration in solution, and anion valency on the adsorption process is noted. The study of gelatine adsorption on small particles of magnetic iron oxide is the subject of work of (Hirotooshi *et al.*, 1997). The authors investigated the adsorption of gelatine depending on various parameters (temperature, pH, salt concentration). It indicates an increase in the adsorption and molecular weight of gelatine with an increase in the initial concentration of gelatine.

Some works are devoted to the study of polymer complexes containing gelatine as one of its components. P.N. Gilsenan, R.V. Richardson investigated the gelatine-pectin cogels (Gilsenan and Richardson, 1998). The effect of the structure of gelatine micellar solutions in the isooctane-water (bis-2-ethylhexyl) sodium sulfosuccinate system on gelation was considered in (Krasovskii and Andreeva, 1996). A number of works covers aqueous systems of gelatine-sodium alginate. The authors (Mukhin and Tolstoguzov, 1980), upon studying the compatibility of proteins and polysaccharides, found that aqueous mixtures of gelatine and sodium alginate at single ionic

strength and pH above the isoelectric point of gelatine are single-phase. An assumption was put forward that the compatibility of gelatine with anionic polysaccharides is conditioned by the formation of complexes of different nature between them. A study of mixed gels of gelatine and calcium alginate (Tolstoguzov, 1980) indicates the existence of two independent spatial networks.

The authors I.V. Fedusenko, T.E. Eryshkanova, V.I. Klenin (Fedusenko *et al.*, 2001) studied the gelation process in the gelatine-sodium alginate-water system with a total polymer concentration of 3 wt. %. It was demonstrated that gelation in the system is conditioned by local crystallization of polymers. When the gelatine content in the polymer mixture is 90%, a complex is formed. Gels of this composition have a higher melting (gelation) point and a greater value of the elastic modulus. Works of I.V. Fedusenko, L.I. Khomutov deal with the rheological behaviour of gelatine + sodium alginate + water system depending on the ratio of gelatine and sodium alginate at a total polymer concentration of (2-4) %. The dependence of the tensile strength of the forming structural formations depending on the content of sodium alginate in the mixture and temperature is shown. The appearance of spatially cross-linked thermoreversible structures in such ternary polymer systems is also discussed (Fedusenko and Khomutov, 1996).

In the work of E.A. Reshetnyak (Reshetnyak *et al.*, 2005), properties of gelatine are compared to modified gelatine (degree of modification of 10, 30 and 85%). Using the method of capillary viscometry, it was demonstrated that upon hydrophobization of gelatine, its macromolecular tangles become more compact and symmetrical. At the maximum degree of hydrophobization of gelatine, its adsorption activity increases by approximately 4 times. Methods were developed for the preparation of a polymer complex of phthaloyl gelatine with proxanol and other additives (Pobedimsky *et al.*, 2000; Elin *et al.*, 2002), characterized by the presence of a significant number of functional groups, large size, and the possibility of being used as a sorbent for wastewater treatment in such industries as petrochemical, pharmaceutical, etc.

A large role is given to the introduction of small additives of gelatine in composite materials, which enables the increase in the physicomechanical properties of composites and reduces their cost. In this regard, the work (Kudaibergenova *et al.*, 2008) studied the possibility of obtaining homogeneous and

interconnected composites on the basis of gelatine and bentonite clay with insignificant amounts of clay (0.2-2%). The degree of swelling of various compositions was determined using a scanning microscope, the morphology and structure of composite gels were determined using a scanning electron microscope, and the rheological properties of the compositions were studied using a Brookfield DV-II+PRO device (USA). An assumption on the formation of complexes through hydrogen bonds is put forward. It is shown that the compositions obtained in terms of homogeneity, stability, interoperability and structure-forming properties correspond to the requirements for carriers of medicinal and biologically active compounds.

The rheological properties of gelatine-calcium and sodium alginates system are also considered in detail in the dissertation of Evtushenko (2008). The work of A.V. Varlamov, A.N. Zuev, E.E. Latinsky (Varlamov *et al.*, 2008) displays that upon hydrophobizing gelatine with succinylauril, the macromolecular tangles become more compact and symmetrical. At the maximum degree of hydrophobization of gelatine, its adsorption activity increases by approximately 4 times. Chemical modification of gelatine with lauric acid succinimide ester changes the rheological properties, greatly changes the hydrodynamic parameters of protein macromolecules.

The structure formation of solutions of various protein molecules was studied in Kazakhstan by A. Zholbolsynova (Kozlov *et al.*, 1984; Zholbolsynova *et al.*, 1992). The process of structure formation in aqueous solutions of edible gelatine in the presence of organic additives (carbohydrates) was studied, the bonds determining the strength of the structure and the conformational transformations of macromolecules were determined. The conformation of gelatine macromolecules was studied by measuring the specific optical rotation. It is shown that the addition of carbohydrates increases the strength of the resulting structure, reduces the induction period. A conformational change in macromolecules accompanies the process of gel formation. It is assumed that the stabilization of the resulting structure is conditioned by hydrophobic bonds and an increase in the number of intermolecular bonds.

Further studies examined the effect of synthetic and biopolymers on the structuring and rheological properties of gelatine (polyvinyl alcohol, polyvinylpyrrolidone, sodium humate and nitrohumate, salts of inorganic acids, carbohydrates, organic alcohols, surfactants)

(Salikova *et al.*, 1999; Salikova and Zholbolsynova, 1999; Salikova and Zholbolsynova, 2000; Salikova *et al.*, 2000; Salikova *et al.*, 2001; Zholbolsynova and Salikova, 2001; Salikova *et al.*, 2002; Bektemisova *et al.*, 2009a; Bektemisova *et al.*, 2009b; Zhakina, *et al.*, 2009; Bektemisova *et al.*, 2009c; Salikova *et al.*, 2014).

### 3. MATERIALS AND METHODS:

Here we consider the effect of sodium carboxymethyl cellulose on the processes of structure formation, the rheological properties of mixed gels and the adsorption processes of gelatine. To clarify the gelation mechanism, we used the kinetic approach, since this allows us to consider the processes of nucleation and formation of spatial structures.

The object of the research in this part of the study was gelatine, on the basis of which experiments were carried out to determine the structure formation in its mixed systems with sodium carboxymethyl cellulose. We used edible gelatine, purified and reduced to an isoelectric state. The moisture content of the preparation is 15%, the ash content is 12%, and the molecular weight is 70.000. Proceeding from the analysis, all previous studies, a working gelatine concentration of 5% was selected. The process of structure formation was studied through the following parameters: structuring time, melting point, ultimate shear stress at different pH.

As in most cases, the polymer-polymer-low molecular weight liquid systems are incompatible with a wide range of component composition changes, the effect of the polymer volume ratio on the structuring process was studied. It was established that mixed gelatine gels are formed at certain optimal ratios. The compatibility criterion was the shape of the viscosity – composition curves. A linear relationship was observed, which signifies the formation of a homogeneous system when the selected components are mixed up to 50% NaCMC in the mixture; when a share of NaCMC in the mixture is above 50% vol., system demixing is observed. As a result of determining the conditions for the formation of mixed solutions, the range of variation of the NaCMC fraction in the mixture of 0÷50 (vol%) was chosen. It was suggested that during the formation of crystalline nuclei, the process will occur at different rates depending on the content of NaCMC. Table 1 presents data on the effect of the NaCMC content in a mixture with gelatine on the structuring time of mixed systems as an indicator of the rate of

formation of three-dimensional structures.

The identification of the structuring time demonstrated that, appropriately, the pH of the medium affects the structure formation of mixed gels. pH = 5, as the isoelectric state of gelatine, due to the lack of resistance to structuring from the side of its charged chains, leads to the shortest time for structuring mixed gels. Because of the change in the properties of gelatine aqueous solutions due to modification of properties of the solvent by the presence of NaCMC, an increase in the content of the modifier in the mixture (up to the previously established limit of 50% vol.) leads to an acceleration of the structure formation process. Kinetic studies of the ultimate shear stress of 5% mixed gelatine gels and NaCMC allowed to identify the time interval necessary to achieve the equilibrium strength of systems equal to 4 days (Figure 1).

To identify the effect of pH of the medium, the composition of the mixture on the melting temperature, measurements were performed for 5% concentrations formed in gel in the course of four days (Table 2).

#### 4. RESULTS AND DISCUSSION:

Since collagen folding is a cooperative phenomenon characterized by high activation energy; therefore, the melting points should be the same regardless of the gel composition. Our results show an increase in  $T_{mel}$ . With an increase in the content of NaCMC, which proves the participation of NaCMC in the stabilization of the network structure. It is necessary to note the distinct melting temperature during the measurement, which is evidence of the network structure of the gel stabilized by secondary forces.

This is because the value of  $T_{mel}$  depends on the relative number of hydrogen and hydrophobic bonds involved in each series of interacting chain segments; the melting temperature rises with an increase in the number of bonds per segment and becomes more defined. The distinctness of  $T_{mel}$  is directly related to the fact that the rupture of interacting pairs of chain segments involves the simultaneous rupture of several bonds. Adding NaCMC to the system does not change the effect of pH. Gels have the highest melting point at pH corresponding to the isoelectric state of gelatine. In parallel with measurements of the melting temperature in the same gels, their tensile strength was identified (Table 3).

It was concluded that the presence of a charge in gelatine macromolecules at a pH other

than the isoelectric state impairs the rheological properties of mixed gelatine gels and sodium carboxymethyl cellulose. Studying the adsorption of biopolymers at the liquid-solid interface is of great practical and theoretical importance. The extremely important role of proteins as biological objects is well known. Proteins provide cell adhesion and tissue formation. For the functional properties of biological systems, the surface activity of proteins is of no small importance. The part of surface phenomena in protein systems is very great in natural and technological processes.

Thus, the study of structure formation in mixed 5% gelatine and sodium carboxymethyl cellulose gels suggests that the synthetic polymer has a positive effect on gelation of gelatine. An increase in the content of NaCMC leads to an acceleration of the gelation process and the formation of stronger spatial structures.

Concentration of proteins at the phase boundaries, technological stages of emulsification and stabilization are widespread in the food, chemical, pharmaceutical industries. In animal husbandry, the use of biopolymers as fillers is known. In addition, surface phenomena involving proteins are often accompanied by structure formation or phase transitions; therefore, the study of adsorption provides additional information on the structuring of aqueous solutions. With that, the adsorption of macromolecular compounds from solutions on a solid surface is most important, since polymer adhesion, structural and mechanical properties of the high molecular weight compound boundary layers, the structure and the most important characteristics of monolayers and various composite materials are associated with it.

An analysis of the literature data shows that most of the experimental work on the study of polymer adsorption was performed using dilute polymer solutions, when intermolecular interaction in solutions can be neglected. However, even in this case it is impossible to draw unambiguous conclusions about the influence of various factors on the adsorption of polymers. Adsorption of biopolymers, in particular gelatine, is devoted to a small amount, especially for the adsorption of mixed solutions of gelatine with artificial polymers. Therefore, we studied the kinetics of adsorption of a mixture of gelatine with sodium carboxymethyl cellulose (NaCMC), the dependence of the adsorption on the amount and nature of the adsorbent, the specific surface of the adsorbent, and the concentration of the mixture. Preliminary studies of the rheological properties established the optimal ratio of gelatine and NaCMC in the

mixture – 1:1. Based on initial experiments, the optimum adsorption temperature was determined – 50°C; lowering the temperature below the optimum value leads to undesirable gelation of the system.

The study of the kinetics of adsorption is important from the standpoint of identifying factors determining the duration of the formation of adsorption layers. A study of the kinetics of gelatine adsorption with NaCMC displayed that the maximum contact time of the studied mixed aqueous solutions is 8-10 hours, the adsorption equilibrium is achieved within 2-3 hours and is practically independent of the mixture concentration; with an increase in the mixture concentration, the adsorption equilibrium is reached faster (Figure 2). The contour of the curves indicates that the experimental points fit well on the Langmuir adsorption equilibrium curve. Achieving equilibrium within a few hours, unlike pure gelatine, when equilibrium is reached faster (30 min-1 hour) (Zholbolsynova *et al.*, 1986), proves structural changes in NaCMC-modified gelatine. Gelatine macromolecules lose their flexibility, the diffusion rate to the surface of a solid decreases.

The established range of variation in the concentration of the adsorbent (0.5-3) g/dl of the solution is optimal for the adsorption of gelatine. The study of adsorption at such amounts of adsorbent (Table 4) allowed to establish the working concentration of the adsorbent equal to 0.5 g/dl of the solution. The decrease in adsorption with increasing adsorbent content can be explained by a decrease in their effective specific surface area due to adsorbent aggregation. The effect of the mixture concentration on the adsorption value of the gelatine and NaCMC mixture is provided in Table 5.

The data indicates that an increase in the concentration of the mixture leads to a larger adsorption value. An increase in the concentration of the mixture above 1% causes system structuring. At a given concentration of the mixture (1%) in the solution, the process of formation of large aggregates begins, including up to several hundred macromolecules of gelatine bonded with NaCMC. The effect of the specific surface area on the adsorption of a mixture of gelatine with NaCMC is presented in Table 6.

With an increase in the specific surface area of the adsorbent, which facilitates adsorption of large aggregates, the specific adsorption of gelatine with NaCMC increases. To identify the effect of the nature of the adsorbent on the specific

adsorption value, a mixed solution of gelatine with NaCMC was adsorbed on alumina oxide, activated carbon, ground brick, bentonite and silica gel (Table 7).

The results indicate that the adsorption of the test mixture depends on the chemical nature of the substrate, which is explained by the influence of the formed adsorption layer, which completely shields the surfaces of any solids. The results show that the best adsorption properties for mixed gelatine systems with NaCMC are hydrophilic surfaces with a well-developed macro- and microstructure of pores, such as silica gel and ground brick (significant intermolecular interactions in the adsorption layer are observed). Non-polar adsorbents with an activated surface, such as activated carbon, are also good adsorbents for gelatine aggregates with NaCMC. Adsorption on charged surfaces of alumina oxide is characterized by a significant energy barrier. The specific adsorption on such surfaces is significantly smaller.

A study of the adsorption of gelatine with NaCMC proves rheological studies, the results display structural changes in NaCMC-modified gelatine. When gelatine is mixed with NaCMC, larger structures and aggregates are formed in the solution, which lead to an increase in the time for the establishment of adsorption equilibrium, which is explained by spatial difficulties in the formation of adsorption layers. It should be noted that the specific adsorption value depends on the quantity and nature of the adsorbent. It was established that hydrophilic and activated surfaces are good adsorbents for gelatine with NaCMC.

Gels of various nature arouse the interest of researchers because of the emergence of the framework in the structure, determining their mechanical properties. Furthermore, a gelatinous state is a common state of natural polymers. The study of the formation of spatial structures of various types in disperse systems, their properties and the management of this process opens up unlimited possibilities for obtaining materials with tailor-made properties.

One of the essential conditions for gelation is to achieve a specific concentration of the solution, the so-called critical concentration, including the limited solubility of the polymer in this solvent. Reducing the interaction of the polymer and the solvent can be achieved by changing the temperature, the nature of the solvent, including the introduction of specific additives into the solvent. Thus, gelation can be enhanced when some additives (alcohols, various salts, heavy

metal oxides, etc.) are introduced into the polymer solution, which lead to the formation of intermolecular or chemical bonds between different polymer macromolecules (Asaubekov *et al.*, 1996). Indirect evidence of the hardening gel structure is its ability to swell. The stabilization of the gel structure can be analysed by its resistance to aging.

The object of research, in this case, was also gelatine, based on which experiments were carried out to determine the swelling and aging of its gels using inorganic salts, such as sodium chloride, calcium chloride, aluminum chloride. In this work, edible gelatine is used, purified, and reduced to isoelectric state. The moisture content of the preparation is 15%, the ash content is 12%, and the molecular weight is 70.000. Based on the analysis of literature data (Zholbolsynova, 1973), the working concentration of gelatine and the amount of sodium, calcium, and aluminum chloride additives were selected. In the research, selective nature of the swelling process (gelatine swells in water and in aqueous solutions and does not swell in liquid organic substances) was considered; therefore, water was used as a solvent for swelling gelatine gels.

The obtained experimental data are presented in Tables 8-10. From the provided data, it follows that the presence of additives of inorganic salts leads to an increase in the swelling of gelatine gels. Thus, the degree of swelling increased by 100% with the addition of sodium chloride, by 73% with the addition of calcium chloride, and by 60% with the addition of aluminum chloride. Investigation of the effect of the pH of the medium on the degree of gelatine swelling in the presence of inorganic salts suggests that a deviation of the pH of the medium from the isoelectric state also leads to a change in swelling degree. At pH = 9 and pH = 3, an increase in the degree of swelling is observed compared to the isoelectric point. With that, at pH = 3, the degree of swelling is somewhat greater than at pH = 9. This is due to the influence of a charge that is distributed throughout the gelatine gel chain at pH = 3 and is localized in certain regions at pH = 9. A similar dependence is observed for gelatine gels both in the presence of sodium chloride and of calcium and aluminum chlorides.

The results also display that aluminum chloride has the greatest effect on increasing the degree of swelling. It turned out that the maximum degree of gelatine gel swelling is observed with the introduction of NaCl, average – with CaCl<sub>2</sub>, minimum – with AlCl<sub>3</sub>. The results on the effect of the anion charge on the gelatine gel swelling

correlate with the results of studying their influence on the ultimate shear stress. With an increase in the anion charge, an increase in the ultimate shear stress (gel strength) occurs, which manifests itself, in this case, in a decrease in the gel swelling, which may be due to an increase in the osmotic pressure inside the network because of the different amounts of low molecular weight ions (Bekturov *et al.*, 1999). Measurement of the degree of swelling of 5% gelatine gel with the introduction of sodium, calcium, and aluminum chlorides allowed to graphically consider the dependence of the kinetics of its swelling on the cation charge at pH = 5 (Figure 3).

Figure 4 demonstrates a characteristic curve of gelatine gel swelling in the presence of NaCl additive depending on pH. From Figure 4 it follows that the degree of swelling depends on the pH of the medium and increases with a shift in pH to the acidic and alkaline regions. At the isoelectric point swelling is minimum.

Gels of macromolecular compounds are not subject to the process of their aging, and a change in some of their properties during prolonged standing is conditioned by the slow action of foreign substances capable of oxidation present in them. It was suggested that the presence of low molecular weight additives in the polymer hydrogel, contributing to the structure formation and hardening of gels, will destabilize the spatial system and contribute to its aging. In this case, we determined the aging of 5% gelatine gel with the introduction of 0.5M sodium, calcium, aluminum chlorides at different pH. The study of aging was carried out through studying changes in the size and mass of the initial sample (gel height,  $\Delta h$ , mm), changes in mass  $\Delta m$ , g.

Measurements were also taken over time. The results are presented in Tables 11-13. The procured data indicate that the presence of salts accelerates the aging process with a content of sodium, calcium, and aluminum chlorides at a concentration of 0.5 mol/L; the procured data correlate with the results of a study of the swelling process. The results of a study of the aging processes in gelatine in the presence of inorganic salts suggests the greater the charge of the anion the greater the presence of salts affects the strength of the gel. The aging process of gelatine hydrogels in the presence of inorganic salts depends on the pH of the medium. Stronger gels are less prone to aging.

## 5. CONCLUSIONS:

The positive effect of sodium

carboxymethyl cellulose on the gelation of 5% gelatine hydrogels was established. An increase in the content of NaCMC in a mixture with gelatine leads to an acceleration of the gelation process and the formation of stronger spatial structures. The participation of NaCMC in stabilizing the network structure was indirectly noted by the distinct melting temperature upon measurement.

The study of surface phenomena at the phase division boundary "mixed gelatine hydrogels – solid medium" indicated that quantitatively the adsorption of the test mixture depends on the chemical nature of the supporting medium, which is explained by the influence of the formed adsorption layer. The best adsorption properties for mixed gelatine systems with NaCMC was established – hydrophilic surfaces with well-developed macro- and microstructure of pores, such as silica gel and ground brick. Non-polar adsorbents with an activated surface, such as activated carbon, are also good adsorbents for gelatine aggregates with NaCMC. Adsorption on charged surfaces of alumina oxide is characterized by a significant energy barrier. The value of specific adsorption on such surfaces is set to be much smaller. The effect of pH on the structuring processes, the adsorption of mixed hydrogels of gelatine as a polyampholytic polymer is confirmed.

The gelation process of gelatine-based hydrogels was also studied from the standpoint of its stability over time in the presence of inorganic salts. It was established that the presence of additives of inorganic salts leads to an increase in the swelling of gelatine gels. The presence of inorganic salts also accelerates the aging process of gelatine hydrogels with a content of sodium, calcium, and aluminum chlorides at a concentration of 0.5 mol/l. The higher the charge of the salt anion, the greater the modification of gelatine hydrogels with inorganic salts affects the strength of the gel. It is established that more durable gels are less prone to aging. The process of swelling and aging of gelatine hydrogels in the presence of inorganic salts also depends on the pH of the medium.

## 6. ACKNOWLEDGEMENTS:

Authors extend their thanks to the professor, Doctor in Chemistry Amina S. Zholbolsynova for assistance with writing this paper.

| 35                  | 47                            | 29 | 32 |
| 50                  | 45                            | 28 | 31 |

**Table 2.** Effect of the composition and pH of 5% of mixed aqueous systems based on gelatine and NaCMC on the melting temperature

| Content of NaCMC, % | Melting temperature, $t_{mel}$ , °C, at pH: |      |      |
|---------------------|---|------|------|
|                     | 3   | 5    | 9    |
| 0                   | 30.1  | 34.5 | 32.5 |
| 15                  | 31.6  | 35.6 | 33.0 |
| 25                  | 32.5  | 36.0 | 34.1 |
| 35                  | 33.1  | 36.5 | 35.2 |
| 50                  | 34.2  | 37.8 | 36.6 |

**Table 3.** Dependence of the maximum strength of 5% mixed gelatine gels and NaCMC on the composition at different pH

| Content of NaCMC, % | Critical shear stress, $P_m$ , kg/m <sup>2</sup> , at pH: |       |       |
|---------------------|---|-------|-------|
|                     | 3   | 5     | 9     |
| 0                   | 150.0   | 250.1 | 250.2 |
| 5                   | 153.3   | 254.3 | 253.6 |
| 15                  | 158.1   | 260.4 | 258.7 |
| 25                  | 163.8   | 268.6 | 263.8 |
| 35                  | 169.1   | 276.1 | 270.2 |
| 50                  | 177.2   | 287.2 | 277.5 |

**Table 4.** Dependence of the specific adsorption of a mixture of gelatine and NaCMC on the mass of silica gel, the concentration of the mixture = 1 %;  $S_{sp} = 14 \text{ m}^2/\text{g}$ ;  $t = 50^\circ\text{C}$

| Adsorbent mass, m, g         | 0.5 | 1.0 | 1.5 | 2.0 | 2.5 | 3.0 |
|------------------------------|-----|-----|-----|-----|-----|-----|
| Specific adsorption, G, mg/g | 423 | 385 | 340 | 290 | 255 | 210 |

**Table 5.** Dependence of the adsorption value of a mixture of gelatine and NaCMC on silica gel on the concentration of the mixture,  $m$  (adsorbent) = 0.5 g;  $S_{sp} = 14 \text{ m}^2/\text{g}$ ;  $t = 50^\circ\text{C}$

| Mixture concentration, C, %  | 0.2 | 0.3 | 0.5 | 0.7 | 0.9 | 1.0 |
|------------------------------|-----|-----|-----|-----|-----|-----|
| Specific adsorption, G, mg/g | 78  | 140 | 223 | 318 | 405 | 423 |

**Table 6.** Dependence of the specific adsorption of a mixture of gelatine and NaCMC on the specific surface of silica gel,  $m$  (adsorbent) = 0.5 g;  $C_{mix} = 1\%$ ;  $t = 50^\circ\text{C}$

| Silica gel specific surface, $S_{sp}$ , m <sup>2</sup> /g | 12  | 14  | 18  | 25  |
|---|-----|-----|-----|-----|
| Specific adsorption, G, mg/g                              | 363 | 423 | 544 | 755 |

**Table 7.** Dependence of the specific adsorption of a mixture of gelatine and NaCMC on the nature of the adsorbent,  $m$  (adsorbent) = 0.5 g;  $S_{sp} = 14 \text{ m}^2/\text{g}$ ;  $C_{mix} = 1 \%$ ;  $t = 50^\circ\text{C}$

| Adsorbent        | Specific adsorption, G, mg/g |
|------------------|------------------------------|
| Alumina oxide    | 366                          |
| Bentonite        | 377                          |
| Silica gel       | 423                          |
| Activated carbon | 646                          |
| Ground brick     | 753                          |

**Table 8.** Kinetics of the degree of swelling of 5% gelatine gels ( $\text{pH} = 5$ ) in the presence of salts

| Concentration of salts, mol/l | Time, h | Swelling degree, $\alpha$ , % |                   |                   |
|-------------------------------|---------|-------------------------------|-------------------|-------------------|
|                               |         | NaCl                          | CaCl <sub>2</sub> | AlCl <sub>3</sub> |
| 0                             | 0       | 0                             | 0                 | 0                 |
|                               | 1       | 18                            | 18                | 18                |
|                               | 3       | 25.6                          | 25.6              | 25.6              |
|                               | 5       | 31.2                          | 31.2              | 31.2              |

**RESUMO**

Durante muito tempo, a principal abordagem da avaliação foi a abordagem normativa, quando as realizações individuais dos estudantes foram comparadas com uma determinada norma (os resultados da maioria dos estudantes). Recentemente, a pesquisa pedagógica doméstica tem desenvolvido uma abordagem baseada em critérios para avaliar o desempenho acadêmico, de acordo com que as realizações dos estudantes são comparadas com o escopo de conhecimento que deve ser adquirido em um estágio específico do treinamento. Este estudo teve como objetivo determinar o papel da avaliação baseada em critérios na formação da alfabetização funcional dos estudantes em ciência da computação e construir um modelo de avaliação baseada em critérios no desenvolvimento da alfabetização funcional além de demonstrar a eficácia dos métodos de formação dos alunos. 'alfabetização funcional em ciência da computação. Os principais métodos de pesquisa foram a metodologia de avaliação baseada em critérios desenvolvida pelos autores e a metodologia de avaliação formativa. Foram analisados alguns elementos da metodologia de avaliação formativa. Para o desenvolvimento adicional da metodologia para a formação da alfabetização funcional dos estudantes em ciência da computação, foi construído um modelo de avaliação baseada em critérios. A introdução da avaliação baseada em critérios permitirá mudar para uma avaliação formativa destinada ao desenvolvimento da competência do estudante. A avaliação, composta por critérios que o estudante entende, o estimula e torna o processo de aprendizado lógico. Com base nos experimentos práticos e na avaliação proposta com base em critérios, foi comprovada a eficácia de métodos para a formação da alfabetização funcional dos estudantes em ciência da computação.

**ABSTRACT**

For a long time, the primary approach to assessment was the normative approach when the individual achievements of students were compared with a particular norm (the results of most students). Recently, domestic pedagogical research has been developing a criteria-based approach to assessing academic achievement when students' achievements are compared with the amount of knowledge that needs to be acquired at a particular stage of training. This study aimed to determine the role of criteria-based assessment in the formation of students' functional literacy in computer science and to build a criteria-based assessment model in the development of functional literacy beyond to demonstrate the effectiveness of the methods of formation of students' functional literacy in computer science. The leading research methods were the criteria-based assessment methodology developed by the authors and the method of formative assessment. Some elements of the methodology of forming evaluation were considered. For further development of the methods for the formation of students' functional literacy in computer science, a criteria-based assessment model has been built. The introduction of criteria-based assessment will allow to switch to a formative evaluation aimed at developing student competence. The evaluation, consisting of criteria that a student understands, stimulates him and makes the learning process meaningful. Based on practical experiments and the proposed criteria-based assessment, the effectiveness of

methods for the formation of students' functional literacy in computer science has been proved.

**Keywords:** *critical assessment, education, results, assessment, computer science.*

## АННОТАЦИЯ

На протяжении долгого времени основным подходом к оцениванию был нормативный подход, когда индивидуальные достижения учащихся сравнивались с определенной нормой (результатами большинства обучающихся). В последнее время в отечественных педагогических исследованиях разрабатывается критериальный подход к оценке успеваемости, когда достижения учащихся сравниваются с объемом знаний, который подлежит усвоению на определенном этапе обучения. Целью данного исследования было определить роль критериального оценивания при формировании функциональной грамотности учащихся по информатике и построить модель критериального оценивания для развития функциональной грамотности, чтобы показать эффективность методов формирования функциональной грамотности учащихся по информатике. Ведущими методами исследования стали разработанная авторами методика критериального оценивания и методика формирующего оценивания. Рассмотрены некоторые элементы методики формирующего оценивания. Для дальнейшей разработки методики формирования функциональной грамотности учащихся по информатике, построена модель критериального оценивания. Внедрение критериального оценивания позволит перейти к формативному оцениванию, направленному на развитие компетентности учащегося. Оценка, состоящая из критериев, понятных ученику, стимулирует его и делает процесс обучения смысловым. На основании практических экспериментов и предложенного критериального оценивания доказана эффективность методов формирования функциональной грамотности учащихся по информатике.

**Ключевые слова:** *критическое оценивание, образование, результаты, оценивание, информатика.*

## 1. INTRODUCTION:

For a long time, the main approach to assessment was the normative approach, when the individual achievements of students were compared with a particular norm (the results of most students) (Yang *et al.*, 2017; Yang *et al.*, 2019). Recently, domestic pedagogical research (Krasnoborova, 2009; Sokolova, 2017; Shalashova *et al.*, 2018; Totikova *et al.*, 2019) has been developing a criteria-based approach to assessing academic achievement, when students' achievements are compared with the amount of knowledge that needs to be acquired at a certain stage of training since there is a need for assessment, the results of which would allow to determine what educational goals a student has achieved. This led to the advancement of such an aspect of assessing as comparing an individual result with predetermined criteria.

Evaluation systems in different countries show that a five-point grading system with vague indicators is traditional and does not satisfy modern educational needs (Müller *et al.*, 2017; Cencelj *et al.*, 2019; Guo and Yan, 2019; Kim, 2019). A multi-point system is conventional, but different countries practice different points; the most optimal, in authors' opinion, is the letter designation of achievements, which means a certain number of points (Haber and Mitchell, 2017; Lookadoo *et al.*, 2017; Buchholtz *et al.*,

2018; Sagimbaeva *et al.*, 2019).

Kazakhstani school education is being developed in accordance with the State Program for the Development of Education of the Republic of Kazakhstan for 2011-2020. The updated educational program is aimed at developing a wide range of functional literacy of students, following international practice, enables students to develop functional literacy and critical thinking. In the program of Kazakhstan on the development of the functional literacy of students for 2012-2016, the results of the development of functional literacy of students and the application of acquired knowledge in practice are indicated as the main competencies.

Currently, Nazarbayev Intellectual Schools JSC, together with the Cambridge University Board of Examiners is developing experimental learning outcomes for each section and topic of the subject in innovative integrated training programs, and ways to assess their achievement. In a primary school (7–10th grades), students learn the same program material over a different period, depending on their abilities, and by the end of the 10th grade, they must achieve the same learning goals. This approach to the organization of the educational process, as it is seen, gives a high result (Sagimbaeva *et al.*, 2019) of training, and in the future, leads to a successful adult life.

In the curriculum for assessing the performance of students of other secondary

schools, in educational materials, practical experience systematically affecting the formation of educational and cognitive competence of students, the established criteria for assessing the achievements of students, who have interdisciplinary sciences, are not defined in advance. Criteria-based assessment in the educational process is not fully understood. Existing assessments and monitoring do not allow to determine whether achievements in the field of education are fully used since the subjective assessment tools used (tests, theoretical questions, control issues, etc. are not criteria for determining the level of knowledge acquisition) (Broadbent *et al.*, 2018; Sagimbaeva *et al.*, 2019)

The establishment of various approaches to assessing competence, personal orientation, the development of a general pedagogical concept based on the development of relationships – all this determines the current trends in the development of the assessment system, and some criteria for assessing the level of required competence are based on a comparison of students' achievements, methodological problems of criteria-based assessment (Carter and Bathmaker, 2017; Sanchez *et al.*, 2017; Alt, 2018; Mohamadi, 2018; Astriawati and Djukri, 2019; Basera, 2019; Palmiero and Cecconi, 2019; Mirmotahari *et al.*, 2019).

Thus, based on the theoretical and practical foundations of world and domestic experience, it can be concluded that as part of the educational process, assessment and control and evaluation activities as a whole act as an independent element of the content of education, requiring development (Azmy and Mokhtar, 2017; Marinkovich *et al.*, 2018; Mohamadi Zenouzagh, 2019; Pastore *et al.*, 2019; Silseth and Gilje, 2019). At the same time, the assessment system allows to receive integral and differentiated information about the educational process, track individual student progress in achieving the planned results, provide feedback for teachers, students, and parents, track the effectiveness of the educational program (Luckin *et al.*, 2017; Meek *et al.*, 2017; Houston and Thompson, 2017; Black and Wiliam, 2018; Tienson-Tseng, 2019).

This study aimed to determine the role of criteria-based assessment in the formation of students' functional literacy in computer science and to build a criteria-based assessment model in the development of functional literacy beyond to demonstrate the effectiveness of the methods of formation of students' functional literacy in computer science.

## 2. LITERATURE REVIEW:

A.A. Krasnoborova (2009), in her article, proposes the author's definition of pedagogical technology for criteria-based assessment. The authors call the pedagogical technology of criteria-based evaluation of students in the framework of educational and cognitive activity a process-effective meta-technology that provides a system of interconnected control and assessment of actions of all participants in the educational process to achieve the goals and objectives of the training.

In the study of E.A Sokolova. (2017) a methodology is developed in which criteria-based internal assessment is included in all stages of the activity-oriented design of teaching the topic of the school geometry course developed in this study. Studies suggest different approaches to assessing results.

The study by M.M. McGill (McGill and Decker, 2019) introduces a Resource Centre (csedresearch.org) designed to provide resources for researchers in primary and secondary computer education. The center has a primary function to provide a centralized location for assessment tools, many of which focus on computing.

Y. Ohashi (Ohashi and Yamachi, 2017) used participant observation and group interviews as research methods, as well as a case code matrix and a qualitative data analysis method. The authors developed assessment criteria for an information volunteer for a training course launched in 1997, in which students participated in educational activities based on information from nearby schools. The study generated 30 cases, which were organized in the following three categories: problems, support, and what they learned from this activity. Each of these categories was further divided into the following subcategories: communication, office work, and training. It was discovered that students could not solve all the problems. Also, students demonstrated different levels of performance, which, according to their conclusion, may be associated with differences in students' academic abilities, as well as with the diversity of activities from school to school.

When determining functional online literacy in the study by K. Dolenc (Dolenc *et al.*, 2015), it is demonstrated that there are differences in reading comprehension when reading offline and online, when using electronic school material in their educational process. The study involved 78

students of the 8th grade of primary school, studying the course "Technology and Science." The authors used individual and adaptive intelligent learning systems (ITS) and, using the assessment of the results, showed that for this form of ITS there is still enough room for optimization, which is a constant method of improvement and updating in such systems.

Priscilla Haring (Haring *et al.*, 2018), examining information on the relationship between game design and player's cognitive processes, explores the use of Bloom's taxonomy in describing a psychotherapeutic game in terms of knowledge and cognitive processing.

The study by Valerie J. Shute (Shute *et al.*, 2011) examines the research literature on the relationship between parental involvement (PI) and academic performance, with a particular emphasis on high school (middle and high school). The results first show how individual PI variables relate to academic achievement, and then move on to a more sophisticated analysis of several variables of the general design described in the literature.

Yuan Wang (Wang *et al.*, 2018), in his studies, showed that assessing the skills of information literacy students is extremely important. This article explores an improved compression criterion, which is based on the entropy of a population in an objective space and the maximum distance in a decision-making space and is used to make a decision about starting a local search. The authors argue that the modified model-based population reinitialisation strategy is designed to enhance the ability of HDEM (hybrid differential evolution with model-based reinitialisation) to search globally for solving complex problems.

Panagiotis Psomos (Psomos and Kordaki, 2011) presents a new model for assessing the pedagogical validity of educational digital storytelling environments (EDSE). This model is based on modern social and constructivist views on learning and consists of sixteen dimensions. The model has the shape of a star called the "Digital Storytelling Pedagogical evaluation star," consisting of sixteen peaks as the number of aspects of the assessment above model. The proposed model can help researchers and designers in the pedagogical analysis of the existing EDSE and in making appropriate decisions for the design of the future EDSE. Besides, this model can help teachers choose the right EDSE so that they can complete specific pedagogical tasks in their classrooms.

Rosário R. (Rosário *et al.*, 2011) analyses the role played by some homework variables in student achievement (proximal and distal), as well as their mediating role in using self-regulatory learning strategies and perceived self-efficacy in the subject area. The focus is on English as a Foreign Language (EFL), and a sample of 591 Portuguese fifth and sixth-grade students is used. The data they obtained confirm the indirect effect of homework on school achievement with the help of the mentioned cognitive and motivational variables (the use of self-regulatory learning strategies and self-efficacy).

Inga Glogger (Glogger *et al.*, 2013) shows in her study teacher preparation for evaluating important components of self-regulatory learning, such as learning strategies, which is an essential aspect of integrating self-regulatory knowledge in the school. The authors argue that training journals can be used to evaluate learning strategies per models of the cyclic process of self-regulatory learning and provide precious formative feedback. A computer-based learning environment (CBLE) has been developed that educates teachers in evaluating learning strategies using instructional journals.

The goal of Manuela Leidinger (Leidinger and Perels, 2012), based on Zimmermann's theory of self-regulation, was to promote a robust learning environment to support self-regulatory learning using teaching materials. Learning materials have been developed that focus on the specific (meta) cognitive and motivational components of self-regulatory learning and are divided into six blocks, with which students from the experimental group worked weekly. In total, 135 fourth-graders took part in the study.

The article by A. Vernon (2011) reviews a model developed by the authors to evaluate non-traditional teaching methods, such as group learning. This model was applied to group training courses, which included innovative enhancements such as group exams and group-based role-playing games. The model required a balanced presentation among the set of learning criteria, grouped into six sets of target criteria; all of them are taken from the literature on group learning. The authors developed a test tool based on this model and presented it to 85 students at the end of three business strategy courses.

Many topical questions were asked by teachers in a study by Vreda Pieterse (Pieterse and du Toit, 2009) in a closed electronic survey to identify possible causes for misrepresentation of questions in assessing knowledge, due to the

students' inability to sufficiently understand their essence. In this study, they tried to extrapolate aspects that could lead to computer science students misunderstanding instructions and scientific research. As a result, they would not be able to solve the very questions that the lecturer wants to evaluate. The authors sought to compile a set of guidelines to address issues related to misunderstanding of the issues raised.

Functional literacy consists of language, legal, environmental, computer, information, and activity literacy. During the current continuous development of the information society, everyone has the opportunity to master information technology and use it according to their own needs, that is, forms their own computer literacy, which is one of the components of students' functional literacy, and it is also known that computer science plays a huge role in the formation of information and technological competencies, which are an integral part of the competencies indicated above.

The expected results of students in computer science provide an opportunity to objectively evaluate their educational achievements and determine their development paths, considering the abilities of each student, also help stimulate students' skills and expect improvement in the quality of the educational process.

In reflecting the assessment of computer science for K-8 teachers, Hannah E. Chipman (Chipman *et al.*, 2019) concluded that one area that has not been fully explored is how grades can affect student confidence and attitudes to CS. It was shown that the threat of stereotype and modality of a test affect the performance of the tested CS.

As a result of studying the functional literacy of students in the work of Anatoly Veryaev (Veryaev *et al.*, 2012), it was shown that functional literacy reflects practical ideas about adaptation to social conditions, and cannot be considered as one of the leading educational goals. It is concluded that the natural-scientific direction of training, in comparison with the humanities, has a more favorable effect on the test results in the framework of tasks proposed by international organizations. As a result, the identification of computer and information literacy levels allowed to test the developed test tasks focused on the Federal State Educational Standard to adjust lectures and practical classes for first-year students at the Computer Science course.

The monograph by H.S. Bhola (1979)

considers assessment as a link in the "ideology for technology" chain, assessment models and approaches, an assessment model for a specific situation, providing assessment in functional literacy programs, classic change measurement protocols, some newly discovered change measurement protocols, implementation data for management and evaluation, particular assessment tasks for employees of functional literacy, data verification, and analysis, design of assessment and interpretation of evaluation results for decision making.

### 3. MATERIALS AND METHODS:

Criteria-based self-assessment: at the beginning of work with this technique, a teacher needs to determine the criteria for assessment with students. A teacher should show by example the levels of achievement of these criteria and how the assessment process will take place. It is also useful to practice evaluating works. Examples of criteria-based self-assessment tools are systems of conditional signals and designations of the level of understanding or mastering by a student of a particular knowledge or skill (for example, "color tracks", "traffic lights", "rulers", "cards +/-").

For criteria-based mutual assessment, maps or sheets of assessment are developed with criteria and levels of achievement or forms of feedback on a work. Weekly reports are sheets that students fill out at the end of the week, containing three questions: What have I learned this week? What questions remained unclear for me? What questions would I ask students if I were a teacher to check if they understood the material?

The mind map (intellect map, concept map) consists of the names of concepts placed in frames; they are connected by lines fixing the relations of these concepts from general to particular. A map is considered from top to bottom, a teacher will be able to determine how well students see the overall picture of an entire course or a single topic.

The introduction of criteria-based assessment will allow switching to a formative evaluation aimed at developing student competence. The assessment, consisting of criteria that a student understands, stimulates him, and makes the learning process meaningful. The criterion approach to assessing students consists in comparing the student's achievements with well-defined, collectively developed criteria well known to all participants in the process. Criteria of assessment are developed for each subject. With proper preparation of the criteria scale, the student

can independently assess the quality of their work, which stimulates the achievement of a higher educational result and the formation of educational independence. The use of criteria-based assessment in the educational system makes it possible to identify and improve the method for assessing student performance with the objective goals of an individual subject, as well as using specific parameters (criteria) that allow students to compete in high school.

#### 4. RESULTS AND DISCUSSION:

Criteria assessment consists of formative and summative assessments. The training manual of the Ministry of Education and Science of the Republic of Kazakhstan (Methodological and educational..., 2017) indicates that formative assessment is an assessment of the current work in the classroom, which is mandatory for this stage of training and the cognitive process. This is the student's current performance indicator, providing feedback between a student and teacher. It helps to identify student difficulties and increase the ability to achieve good results. A student should be able to fill current gaps in learning, considering the recommendations of a teacher, with the advice of other students, completing the remaining or additional tasks.

Summative assessment is a cumulative form of assessment that is carried out at the end of a specific training period (quarter, trimester, academic year), and also after mastering the section (Methodological and educational ..., 2017). Following the curriculum, the criteria-based assessment is conducted continuously by a teacher, provides feedback between a teacher and students, and allows timely correction of learning processes, not only scores, grades. A total assessment of sections/general topics is carried out by a teacher 2-3 times a quarter. The final quarterly assessment is carried out by a teacher at the end of each quarter. Summative assessment to determine the level of knowledge is carried out at the end of the primary, principal, senior grade. The funded system records only the achievements of students; therefore, actively encourages students to self-study and cognitive activity, to the full mastery of the curriculum. Standards, methods, and means of assessment vary depending on the type of assessment and subject specificity. The authors present the developed criteria-based evaluation model in the form of a scheme (Figure 1). Consider the techniques of formative assessment (Figure 2). Each of them is based on different criteria.

Computer science training mainly involves the development of user skills, in particular computer skills and new technologies. Therefore, when studying some topics, practical work on the computer is conducted. When developing and testing experimental integrated educational programs in subjects, the authors partially began to use the approach used by Nazarbayev Intellectual Schools in conjunction with the Examination Council of the University of Cambridge.

The authors want to focus on the practice of preparing assignments and carrying out SAS (summative assessment of a section) and SAQ (summative assessment of a quarter) when teaching computer science. When developing tasks of SAS and SAQ with the use of criteria-based assessment at computer science lessons and meeting the requirements of the modern system of updated content in training, it is necessary to strive to develop students' thinking, to provide an opportunity to analyse the proposed situations, thereby students learn to analyse and evaluate their critical thinking. When developing test tasks in the SAQ, it is necessary to adhere to the test specification (ST), where the learning objectives and tested skills are predefined.

For example, consider the topic "Measuring information and a task" in the "Computer" section (Table 1). It is possible to accept tasks in the form of tests (Table 2).

For an objective and evidence-based verification of the validity of the pedagogical hypothesis, a pedagogical experiment was conducted using the following methodology. As a result of measuring the same indicator using the same measurement procedure, the following data are obtained:  $x = (x_1, x_2, \dots, x_n)$  – sample for the experimental group and  $y = (y_1, y_2, \dots, y_m)$  – for the control group, where  $x_i$  – the sample element – is the value of the studied indicator (feature1) for the  $i$ -th member of the experimental group,  $i = 1, 2, \dots, n$ , and  $y_j$  is the value of the studied indicator for the  $y_j$ -th member of the control group,  $j = 1, 2, \dots, m$ . The number of sample elements is called its size — for example, the size of sample  $x$  is  $N$ , and the size of sample  $y$  is  $M$  (Novikov, 2004).

Measurements were made on the *ratio scale* (time, number, etc.),  $\{x_i\}$  and  $\{y_j\}$  – positive, including natural numbers, for which all arithmetic operations make sense. The measurement consists in determining the level of knowledge by conducting a test that includes 20 tasks. It is assumed that the characteristic of a student (sign) is the number of correctly solved problems.

The authors use an *ordinal scale* (rank scale) with  $L$  gradations; it is assumed that  $\{x_i\}$  and  $\{y_j\}$  are natural numbers that take one of  $L$  values. A set of values (points) is a set of numbers from one to  $L$ . A characteristic of a group will be the number of its members who have gained a given score. That is, for the experimental group, the point vector is  $n = (n_1, n_2, \dots, n_L)$ , where  $n_k$  is the number of members of the experimental group who received the  $k$ -th point,  $k = 1, 2, \dots, L$ . For the control group, the point vector is  $m = (m_1, m_2, \dots, m_L)$ , where  $m_k$  is the number of control group members who received the  $k$ -th point,  $k = 1, 2, \dots, L$ . Obviously,  $n_1 + n_2 + \dots + n_L = N$ ,  $m_1 + m_2 + \dots + m_L = M$ .

Here are the formulas for calculating the main indicators. The arithmetic mean  $\bar{x}$  of the sample  $\{x_i\}_{i=1}^N$  (sample mean) is calculated as follows (Equation 1) and the sample dispersion  $D_x$  (Equation 2). For the data measured in the ratio scale, to test the hypothesis that the characteristics of the two groups coincide, it is advisable to use the Cramer-Welch criterion. The Cramer-Welch criterion is designed to test the hypothesis of equality of means (strictly speaking, mathematical expectations) of two samples.

The empirical value of this criterion is calculated on the basis of information about the volumes  $N$  and  $M$  of samples  $x$  and  $y$ , sample means  $\bar{x}$  and  $\bar{y}$ , and sample dispersions  $D_x$  and  $D_y$  of the compared samples (these values can be calculated manually using formulas (1)-(2) or using the tool "Descriptive statistics" in the computer program Microsoft Excel according to the following formula (Equation 3):

Descriptive statistics, firstly, allows presenting the results of a pedagogical experiment in a compact and informative form, which makes it possible to conduct a qualitative analysis of the objects studied. Secondly, several indicators of descriptive statistics are used in quantitative analysis (when applying statistical criteria). The algorithm for determining the accuracy of coincidences and differences in the characteristics of the compared samples for the experimental data measured in the ratio scale using the Cramer-Welch criterion is as follows:

1. To calculate for the analyzed samples the  $T_{\text{emp}}$  – the practical value of the Cramer-Welch criterion according to formula (3).

2. To compare this value with the critical value  $T_{0.05} = 1.96$ : if  $T_{\text{emp}} \leq 1.96$ , then conclude: "the characteristics of the compared samples coincide at a significance level of 0.05"; if  $T_{\text{emp}} > 1.96$ , then conclude "the reliability of differences in

the characteristics of the compared samples is 95%".

Experimental training was conducted in several schools in Almaty. Students were divided into experimental and control groups. The purpose of the pedagogical experiment was to verify the effectiveness of the developed system of tasks and tests and the authors' proposed methodology for the formation of students' functional literacy in computer science.

In the experimental and control groups, the SAQ was carried out according to the authors' tasks and tests. The experimental group consisted of  $N = 15$  people, and the control group consisted of  $M = 20$  people. The results of measurements of the level of knowledge in the control and experimental groups before and after the experiment are shown in Table 3.

The experimental results are also obtained in the ordinal scale. For  $N = 15$ ,  $M = 20$ , there are three levels of knowledge  $L = 3$ : low (the number of solved problems is less than or equal to 10), medium (the number of solved problems is strictly bigger than 10, but less than or equal to 15) and high (the number of solved problems is strictly bigger than 15). The authors form Table 4, in which the upper limits of the ranges are indicated (Figure 3).

For the measurement results in the ratio scale (Table 4), the descriptive statistics indicators were divided into several groups: position indicators describing the position of the experimental data on the numerical axis; scatter indicators describing the degree of spread of data relative to its center (average value). These include sample dispersion, the difference between the minimum and maximum elements (range, sampling interval), etc.; asymmetry indicators: the position of the median relative to the average, etc.

These indicators were used for visual representation and primary ("visual") analysis of the results of measurements of the characteristics of the experimental and control groups. Descriptive statistics for the first column of Table 3 (the number of correctly solved problems in the control group before the start of the experiment) are shown in Table 5.

The authors review the algorithm for determining the accuracy of coincidences and differences in the characteristics of the compared samples for the data from Table 1, measured in the ratio scale, using the Cramer-Welch criterion (Table 6). To do this, first, it is needed to compare the number of correctly solved problems in the

control and experimental groups before the experiment. The authors calculate by the formula (3) the value of  $T_{\text{emp}} = 0.84 \leq 1.96$ . Therefore, the hypothesis that the characteristics of the control and experimental groups coincide before the start of the experiment is accepted at a significance level of 0.05.

Now compare the characteristics of the control and experimental groups after the end of the experiment. The authors calculate by the formula (3) the value of  $T_{\text{emp}} = 2.04 > 1.96$ . Therefore, the reliability of differences in the characteristics of the control and experimental groups after the end of the experiment is 95%.

So, the initial (before the start of the experiment) states of the experimental and control groups coincide, and the final ones (after the end of the experiment) are different. Therefore, it can be concluded that the effect of changes is due precisely to the application of the experimental teaching methodology.

## 5. CONCLUSIONS:

The study of criteria-based assessment as a way of forming students' functional literacy in computer science and the results of experimental work have led to many conclusions:

1. The necessity to ensure the mastery of the primary content of the subjects studied and the formation of functional literacy among schoolchildren in seven key competencies require the development of a new system for assessment by criteria.

2. The basic content of education involves objective results aimed at enhancing the functional, including practical, focus of training. Despite the different number of points in the assessment and the divergence of opinions on this issue in different countries, in all of these systems the unifying core is the criterion of assessment and the differentiation of the levels of assimilation of educational material of students.

3. The process of developing functional literacy among schoolchildren determines the introduction of a new assessment system that takes into account the effectiveness of all types of educational activities, the procedural side of learning material, and the manifestation of individual and personal qualities of students.

4. When studying in the elementary school (7–10th grades), the same program material for a different period, depending on individual abilities, by the end of the 10th grade, students should

achieve the same learning goals. This approach to the organizing the educational process gives a high learning outcome, and in the future, leads to a successful adult life.

5. The assessment system allows to receive integrated and differentiated information about the educational process, track individual student progress in achieving the planned results, provide feedback for teachers, students, and parents, track the effectiveness of the educational program.

As a result of the study, the following results were obtained:

1. For further development of the methodology for the formation of students' functional literacy in computer science, a criteria-based assessment model has been built.

2. Based on practical experiments and the proposed criteria-based assessment, the effectiveness of methods for the formation of students' functional literacy in computer science has been proved.

#### RESUMO

O Movimento Harmônico Simples (SHM) é um dos tópicos básicos da física que subjaz a outros conceitos e está intimamente relacionado à vida cotidiana e à tecnologia. É usado para entender os fenômenos de movimento mecânico, som, luz e teoria quântica, em particular, osciladores harmônicos. O objetivo do estudo foi investigar a compreensão conceitual dos alunos sobre o movimento harmônico simples no sistema massa-mola. A coleta de dados foi realizada por meio de testes e entrevistas. Os sujeitos da pesquisa consistiram em 49 estudantes em uma universidade em Jacarta. Os instrumentos utilizados foram tarefas de múltipla escolha. Os resultados da investigação mostraram que a maioria dos estudantes não conseguiu dominar bem os conceitos básicos do movimento harmônico simples, determinar a magnitude da aceleração dos objetos devido à oscilação e encontrar o escopo do período de oscilação. Os resultados mostram que o desempenho médio dos alunos é inferior a 50%. A falta de compreensão da concepção do aluno é causada pelo fato de os alunos não conseguirem relacionar conteúdos anteriores (como a lei de Newton e a lei de Hooke) com estratégias para resolver problemas.

**Palavras-chave:** *Investigação, compreensão de conceitos, Lei de Hooke, movimento harmônico simples, sistema de massa-mola.*

#### ABSTRACT

Simple Harmonic Motion (SHM) is one of a primary physics topic that underlies other concepts and is closely related to everyday life and technology. It is used to understand the phenomena of mechanical motion, sound, light, and quantum theory, in particular, harmonic oscillators. This study aimed at investigating students' conceptual understanding of simple harmonic motion on the mass-spring system. Data collection was made using tests and interviews. The research subjects consisted of 49 students at a university in Jakarta. The instruments used were multiple-choice tasks. The results of the investigation showed that most students have not been able to name the basic concepts of simple harmonic motion, determine the magnitude of the acceleration of objects due to oscillation, and find the scope of the oscillation period. The results show that the average achievement of students is less than 50%. Lack of understanding of student conception is caused by students not being able to relate previous insights (such as Newton's law and Hooke's Law) with strategies for solving problems.

#### 1. INTRODUCTION:

Nowadays, research in the field of physics education, in particular, understanding student concepts, is a research trend that is studied in depth. Understanding concepts is one of the main objectives in learning physics (Adolphus, Alamina, Aderonmu, Education, and State, 2013; Arista and

Kuswanto, 2018; Eldy and Wui, 2019; Krinks, 2016; Maison and Syamsurizal, 2019; Ogundéji, Madu, and Onuya, 2019; Olmstead, 2019; Somroob and Wattanakasiwich, 2017; Son, 2017), so that with a good understanding of the concept students can apply it in everyday life (Dimas, Suparmi., Sarwanto., and Nugraha., 2018; Nugraha, Suparmi, Masykuri, and Cari, 2016).

Physics is the study of matter, energy, and its interactions. Physics plays a key role in the progress of humanity; in this case, physics, as a basic concept for technological advancements needed to drive the world economy (Adolphus *et al.*, 2013). Simple Harmonic Motion (SHM) is one of the physical materials that is closely related to everyday phenomena; it is used to understand the phenomena of mechanical motion, sound and light, and quantum theory in particular harmonic oscillators (Adolphus *et al.*, 2013; Alho, Silva, Teodoro, and Bonfait, 2019; Greene, Gill, and Eyerly, 2016; Parnafes, 2010).

The application of SHM concepts in daily life can help students identify and shape their knowledge (Khowatim, Mahardika, and Alex, 2017). Some real-world phenomena, such as simple harmonic motion, require an understanding of the concepts of coordinates in various wave functions (Parnafes, 2010). So it can be said that the understanding of SHM concepts that must be understood by students both in theory and mathematical calculations (Adolphus *et al.*, 2013). By learning how students understand physics, and their attitude towards learning physics is something interesting to study (Angell, Guttersrud, Henriksen, and Isnes, 2004; Son, 2017). It aims to improve the quality of physics learning.

The quality of physics learning has a positive correlation between teacher mastery of physics material and better pedagogical practices (Dandare, 2018). The results of research conducted by Dandare (2018), revealed that there are gaps in physics teachers regarding simple harmonic motion material.

Therefore, the aim of this study was to investigate students' conceptual understanding of simple harmonic motion on the mass-spring system.

## 2. LITERATURE REVIEW:

Understanding the concept is a process of adaptation and transformation of science (Gardner, 1999). Concept mastery is the result of student learning in the form of achieving the competence of physics courses in the cognitive domain. A scientific concept is expressed in various levels and presented or generalized in curriculum standards (OECD, 1999). The concepts of students are explored and developed using logical reasoning skills, training, formulating theories, and participation in problem-solving so that students can create an accurate conclusion (Nurhuda, Rusdiana, and Setiawan, 2017).

Physics learning aims to make students obtain many concepts and apply or apply flexibly (Reif, 1995). To represent the concept of physics requires an exceptional understanding of the idea. In other words, the multi-representation ability is closely related to understanding student concepts. The representation can be interpreted as a description of the relationship between objects and symbols (Hwang, Chen, Dung, and Yang, 2007). The connection with learning physics representation aims to describe a concept/object/phenomenon using specific symbols, including words/verbal symbols, diagrams/pictures, graphs, and mathematical symbols.

While multi-representation is a way to represent a concept in the form of different representations. Waldrip *et al.* (2006: 87) define multiple representations as practices to describe the same idea through various ways, which include descriptive descriptions (verbal, graphs, tables), experimental, mathematical, figurative (pictorial, analogy, and metaphorical), kinesthetic, visual and operational-operational (Waldrip, Prain, and Carolan, 2006). Merging these representations complement each other, making it easier for students to understand concepts and solve problems.

Multirepresentations have three main functions, namely as a complementary, limiting interpretation, and understanding builder (Ainsworth, 2006). Multirepresentations support the inculcation of concepts by providing supplementary information about an idea, limiting the possibility of errors in the use of other representations, and helping to build deeper understanding by increasing abstraction, helping generalization, and building relationships between representations. Learning process by using multi representation models effectively to enhance students' understanding of concepts (Fatmaryanti and Nugraha, 2019).

Simple harmonic motion (SHM) is one of the materials taught in basic physics courses. Some research has been done on understanding concepts and learning from SHM material. Research by Somroob (Somroob and Wattanakasiwich, 2017) shows most students have misconceptions about the recovery style, and they have problems connecting mathematical solutions with real movements, especially phase angles. Also, they have issues with interpreting mechanical energy from charts and motion diagrams (Somroob and Wattanakasiwich, 2017).

### 3. MATERIALS AND METHODS:

#### 3.1. Research Design

This research method was surveying with qualitative analysis. The instrument used in this research was developed from some source such as the Serway and Jewett physics textbook, AP Physics SHM test, and SHM-CS (Hammer, 1996; Nugraha, Cari, Suparmi, and Sunarno, 2019; Serway and Jewett, 2004; Somroob and Wattanakasiwich, 2017). The instrument have been validated before use. The tool consists of twelve items. The distribution of items used is presented in Table 1. The topic discussed in this study is the mass-spring system with six items. The data was analyzed qualitatively compared with the result of unstructured interviews with students. The interviews conducted to clarify student reasoning due to their answer (Lee and Park, 2013; Waldrup, Prain, and Sellings, 2013).

#### 3.2. Research Subject

The sample used in the study were students in the physics education program at Indraprasta University. This study held in indraprasta with permission from the lecturer or physics education at Indraprasta University in 2019. The sample selection uses a purposive sampling technique with a total sample of 49 students. Purposive sampling is sampling based on specific considerations based on researchers' criteria (Patton, 2014; Teddlie and Tashakkori, 2009).

#### 3.3. Instrument

The instrument was a conceptual survey that is used to determine the level of students' understanding after they have completed a series of physics learning. The instrument used was in the form of a reasonable multiple choice that was adopted. The instrument is developed from a daily phenomenon and combine with the theories. The validated instrument consists of some concepts about simple harmonic motion. The concepts included (1) Direction of the normal force vector and the gravity; (2) Basic concepts of simple harmonic motion; (3) Acceleration of the object due to oscillation, and (4) System oscillation period. The distribution of items in each concept is presented in Table 1.

**Table 1.** Distribution of Question Items for Concept Understanding Instrument

| No | Sub Concept Material Mass-Spring System              | Number of Items |
|----|--|-----------------|
| 1  | Direction of the normal force vector and the gravity | 1               |
| 2  | Basic concepts of simple harmonic motion             | 2               |
| 3  | Acceleration of the object due to oscillation        | 2               |
| 4  | System oscillation period                            | 1               |

Before an analysis of students' conceptual understanding is carried out, a study of the characteristics of the instrument is conducted. The features of the instruments used, referring to the modern test theory. Analysis of instrument characteristics using the Quest program, the results of the study are presented in Table 2.

**Table 2.** Characteristics of Concept Understanding Assessment Instruments

| No | Review                                 | Estimates for Items | Estimates for Testees |
|----|--|---------------------|-----------------------|
| 1  | Average values and standard deviations | .00 ± .26           | .03 ± .40             |
| 2  | Reliability                            | .65                 | .79                   |
| 3  | Average values and standard deviations | 1.00 ± .10          | 1.00 ± .39            |

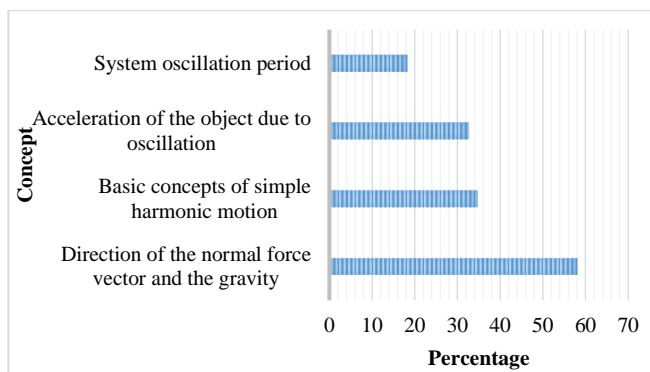

The assessment instrument has a mean INFIT MNSQ of 1.00 and a standard deviation (SD) of 0.10, meaning that overall the items developed are fit with the Rasch model. This is following the opinion of Aminah (2017), which states that the mean INFIT MNSQ 1.01 and SD 0.09. It means that overall the items are under the Rasch model (Aminah, 2017). While the reliability estimation results obtained the value of person reliability 0.79, and item reliability 0.65. It can be concluded that the consistency of the answers both from the TESTEE (a person subjected to a test/One who takes or has taken a test) or from the item has high reliability.

### 4. RESULTS AND DISCUSSION:

#### 4.1. Overall Performance

Investigating students' understanding of concepts is carried out on students who have to learn fundamental physics courses, especially simple harmonic motion (SHM). The results of the student answer analysis, in general, presented in

Figure 1.

**Figure 1. Investigations on the Student Concepts Understanding in the Mass-Spring System Material.** Source: The author

Figure 1 shows that the four aspects which consist of the basic concepts of simple harmonic motion, determining the magnitude of the acceleration of objects due to oscillation, and finding the importance of the system oscillation period are still below 50%. In contrast, the concept of the normal force and gravity vector is above 50%. These results indicate that most students have not been able to understand the concept of SHM in an elaborate manner. These results are consistent with Ambrose's research, which shows that students have difficulty mastering basic concepts to hamper their understanding of more complex ideas (Ambrose, 2007).

#### 4.2. Normal force vector and the gravity

The investigation results of students' conceptual understanding in determining the direction of normal force and gravity vectors get an average percentage of about 58.16%. The items used were two items, in the first item as many as 19 (38.77%) students answered correctly, and in the second item as many as 38 (77.55%), students answered correctly. This result shows that most students have difficulty in answering the first problem. The basic concept in the first problem can be solved by knowing the concept of force resultant.

The resultant force on blocks placed on the floor is zero. Based on Newton's second law, there are two quantities of force that balance each other. For example, a block rests on the floor, and then the floor exerts a force upward. The upward (normal) force applied by the floor to the block is often called the touch force because it occurs in two objects that touch. When the normal force is perpendicular to the surface of the touch plane, the force is usually called the normal force. There are three types of the "zero" meaning in the equation

of Newton first law. Zero as (1) the "zero intuitive", which means "nothing", (2) a "zero number" which used to represent numbers and (3) a "mathematical zero" according to modern mathematics (Qiang and Dong, 2007). The problem given is in the form of two blocks connected by a massless spring when in a stationary position, which presented in Figure 2.

**Figure 2. Item Problem about Concept of Gravity and Normal Force.** Source: The author

Normal Force is a force acting on a plane that touches between two surfaces of an object, whose direction is always perpendicular to the touch plane. The normal force symbol is  $N$  and the International System unit is  $\text{kg m/s}^2$  or Newton. Most students are able to answer this problem correctly. Examples of student answers are presented in Figure 3.

**Figure 3. Examples of Student Answers on Item about Concepts of Gravity and Normal Force.** Source: The author

Figure 3 is an example of a student who is unable to answer this problem well. This can be seen in the answers the student chooses the answer C. The reason given by the student is because the option C block shows masses of  $m_A$  and  $m_B$  as equal, and produces a force with equal pressure. These results indicate that the student is not able to master the basic concepts of the gravity

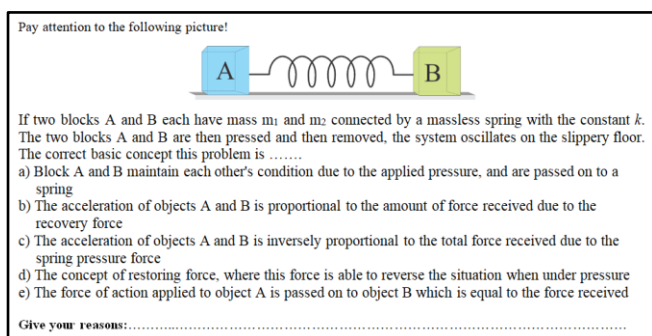

well. This finding proved that the mathematical presentation of students' understanding can be used to identify the zero intuition experienced of students (Handhika, Cari, and Suparmi, 2017). In any case some students can interpret that no forces are acting on the object on the Newton first law concepts (Hsu, 2001).

These results are consistent with Ambrose's research, which shows that students have difficulty mastering basic concepts to hamper their understanding of more complex concepts (Ambrose, 2007). Other research conducted Nugraha, *et al.* (2019) shows that the student's inability to master the basic concepts of the simple harmonic motion is in determining the relationship between distance, speed, and acceleration.

The concept of normal force direction is always perpendicular to the touchpad (Giancoli, 2019; Serway and Jewett, 2004). If the touch plane between two objects is horizontal, the direction of the normal force is vertical. If the plane of the touch is vertical, then the direction of the normal force is horizontal. If the plane of the tilt is tilted, then the direction of the normal force will also be tilted. The base or vector capture point starts from the point where two surfaces of objects touch and then draw a perpendicular line through the center of mass of the object.

#### 4.3. Basic concepts of simple harmonic motion

The investigating results of students' understanding of concepts about basic concepts of simple harmonic motion get a percentage of 34.65% or as many as 17 students who managed to answer correctly. These results indicate that most students have difficulty in determining the basic concepts of simple harmonic motion. Oscillation motion is the movement of an object back and forth over the same path. An example of a simple case is the oscillation motion of an object with mass  $m$  placed at the end of spring, as in Figure 4.

**Figure 4.** Item of Basic Concepts of Spring Oscillation. Source: The author

Figure 4 is an example of an item that visualizes the concept of oscillating motion on a spring on a slippery floor so that there is no friction. If the spring is pushed to the left or right with a displacement of  $x$ , after the thrust is removed, the spring will try to return to the equilibrium position. The force applied by the spring to return to its original position is called the restoring force. Because the force acting on an object is not constant, the acceleration of the object is also not constant but is proportional to the magnitude of the restoring force. The acceleration is directly proportional to the position of the block, and the direction is opposite to the displacement from the equilibrium position. An object experiences simple harmonic motion when its acceleration is directly proportional to its position and in the opposite direction to its movement from equilibrium

The results showed that most students answered correctly on this item. However, there are still some students who have difficulty understanding the basic concepts of spring oscillations. One example of students who cannot solve this problem properly is presented in Figure 5.

**Figure 5.** Examples of Student Answers on Item Basic Concepts of Spring Oscillation. Source: The author

Figure 5 is an example of a student who is unable to answer this problem well. This can be seen in the answers students choose the answer choice D. The reason given by the student is that when A and B are pressed, the spring force will give the same restoring force to A and B.

These results indicate that the student is not able to master the basic concepts of the gravity well. These results are consistent with Ambrose's research, which shows that students have difficulty learning basic concepts to hamper their understanding of more complex concepts (Ambrose, 2007). This is in line with the results of the study (Parnafes, 2010) that in some problems, students have not been able to understand the basic concepts of mechanical motion as a basis for understanding simple harmonic motion. These concepts include the concept of instantaneous speed, frequency, and average speed.

#### 4.4. Acceleration of the object due to oscillation

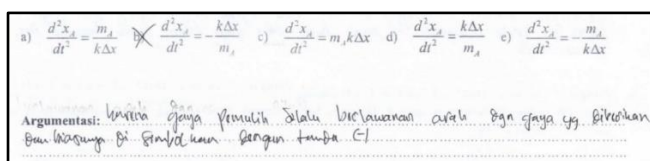

The results of investigating students' understanding of concepts in determining the magnitude of the acceleration of objects due to oscillation, with an average percentage of 32.65%. The items used were two items, in the first item as many as 18 (36.73%) students answered correctly, and in the second item as many as 14 (28.57%), students answered correctly. These results indicate that most students have difficulty in answering the second question. The basic concept in the second problem can be solved by knowing Newton's second law concept.

The restoring force is the force that leads to an equilibrium position and is, therefore, the opposite of the displacement of an object from its equilibrium. By using Newton's second law  $\sum F_x = ma_x$ ,  $F_x$  is Hooke's law that is the force produced by a spring on a block is directly proportional to its position. The item used to determine the students' understanding of the concept of accelerating the oscillation of the mass-spring system is presented in Figure 6.

**Figure 6.** Item about the Concept of Acceleration of Mass-Spring System Oscillation. Source: The author

The results showed that most students answered correctly on this item. But there are still some students who have difficulty understanding the concept of accelerating the oscillation of the mass-spring system. One example of students who cannot solve this problem properly is presented in Figure 7.

**Figure 7.** Example of Student Answers on the Concept of Acceleration on Mass-Spring System Oscillation. Source: The author

Figure 7 is an example of a student who is unable to answer this problem well. This can be seen in the answers students choose the answer choice B. The reason given by the student is

because the recovery style is always in the opposite direction to the force given and is usually symbolized by a negative sign (-). This finding shows that the student answers the item using his perception without using the correct theoretical basis.

These results indicate that students have not been able to use mathematical equations in solving problems. They need guidance on mathematical operations, and which factors affect the acceleration of the oscillation of the mass-spring system (Ambrose, 2007). When block A moves at any time at the reference point symbolized by  $x_{1A}$  and Block B moves at all times at the reference point symbolized by  $x_{2B}$ . Then the length of the spring at any given moment is:

$$x_{2B} - x_{1A} \quad (1)$$

If the difference is the length of the spring  $x_{2B} - x_{1A}$ , then there is a long increase in the spring. The addition of spring length can be written:

$$X = (x_{2B} - x_{1A}) - x_0 \quad (2)$$

or

$$x_{2B} - x_{1A} = X + x_0 \quad (3)$$

Where  $x_0$ , is the initial length of the spring, based on Newton's Second Law, the magnitude of

restoration force is obtained  $F_p = m_A \frac{d^2 x_{1A}}{dt^2}$ .

Remember that FP is a restorer style, by entering the Hooke Law equation, obtained:

$$\frac{d^2 x_{1A}}{dt^2} = \frac{kX}{m_A} \quad (4)$$

The results obtained are functions  $x(t)$  that satisfy the second-order differential equation. This function is a mathematical representation of the position of objects as a function of time. Most of the students have not been able to master the mathematical representation of the concept of a mass-spring system.

#### 4.5. Find the magnitude of the system oscillation period

The results of investigating students' understanding of the concept in determining the period of system oscillation get a percentage of

18.36%. Students who managed to answer correctly on this item were nine people. These results indicate that most students have difficulty in determining the period of system oscillation. The motion period (T) is the time interval required for the particle to go through one full cycle of its motion. The items used to find the magnitude of the system oscillation period is presented in Figure 8.

**Figure 8.** Item about Oscillation Period Mass-Spring System. Source: The author

The item in Figure 8 requires students to be able to find the system oscillation period. Based on the results obtained in the previous problem, obtained acceleration of object A. In the same way, the acceleration of object B is:

$$\frac{d^2 x_2}{dt^2} = -\frac{k \Delta x}{m_B} \quad (5)$$

A negative value on the recovery force indicates the opposite direction of the force. Equations (4) and (5) are substituted:

$$\frac{d^2 x_{2B}}{dt^2} - \frac{d^2 x_{1A}}{dt^2} = -\frac{kX}{m_B} - \left( \frac{kX}{m_A} \right)$$

$$\frac{d^2 (X + x_0)}{dt^2} = -k \left( \frac{m_A + m_B}{m_A m_B} \right) X$$

Since  $\frac{d^2 x_0}{dt^2} = 0$ , then we get:

$$\frac{d^2 X}{dt^2} + \frac{k}{\left( \frac{m_A m_B}{m_A + m_B} \right)} X = 0$$

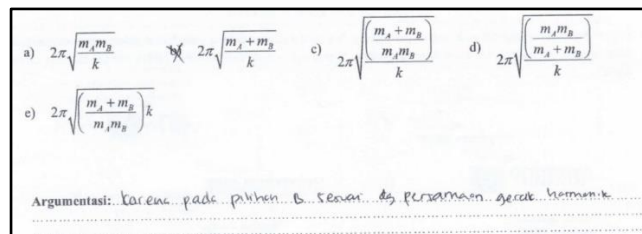

Because the motion that occurs is a simple

harmonic motion, it applies  $\frac{d^2 x}{dt^2} + \omega^2 x = 0$ , then we get:

$$\omega^2 = \frac{k}{\left( \frac{m_A m_B}{m_A + m_B} \right)}$$

$$T = 2\pi \sqrt{\frac{\left( \frac{m_A m_B}{m_A + m_B} \right)}{k}} \quad (6)$$

The mathematical representation of the simple harmonic motion of the period of motion (T) is the time interval required for a particle to go through one full cycle of its motion. The size of the period depends on the mass of the block and the magnitude of the force of the bag and has no effect on the motion parameters (Triana and Fajardo, 2012). Like, amplitude A or phase angle  $\phi$ . The results showed that most students were not able to answer correctly on this item. One example of students who cannot solve this problem properly is presented in Figure 9.

**Figure 9.** Examples of Student Answers in determining the Mass-Spring System Oscillation Period. Source: The author

Figure 9 is an example of an inability of students to answer this problem well. This can be seen in the answers students choose the answer choice B. The reason given by the student is because the choice B matches the harmonic motion equation. These results indicate that most students are not able to grasp the meaning or meaning of a concept. While the concept is an abstraction that represents an object or event obtained based on one's experience. Learning concepts is one of the main objectives of learning.

One of the goals of learning physics is to improve the understanding of student concepts through a quality teacher or lecturer teaching system. Thus, an effective teacher is one who must have a teacher who is more rooted in knowledge about the subjects being taught, the sharpness of teaching skills in the classroom,

following developments in the topic (field) and in education in general, generating and contributing new knowledge to the profession (Adolphus *et al.*, 2013).

The results of the study are generally based on four concepts: direction of the normal force vector and the gravity, basic concepts of simple harmonic motion, acceleration of the object due to oscillation, and system oscillation period is still below 50%. On the other hand, the concept of normal force and gravity vector is above 50%. These results indicate that most students have not been able to understand the concept of SHM in a complex manner. These results are consistent with Ambrose's research, which shows that students have difficulty mastering basic concepts to hamper their understanding of more complex concepts (Ambrose, 2007). The concepts students have can be obtained from daily experiences, learning processes, media, and so on (Aretz, Borowski, and Schmeling, 2016).

## 5. CONCLUSIONS:

Most students have not been able to master the concept well. The students' understanding of concepts is not good, namely, the basic concepts of simple harmonic motion, determine the magnitude of the acceleration of objects due to oscillations, and find the magnitude of the oscillation period. Based on the result, it shows that understanding concepts isn't as simple as it said. Lack of understanding of student concepts is caused by students not being able to relate previous insights (such as Newton's law concepts, and Hooke's Law) with strategies for solving problems. This is shown from the results of the average achievement below 50%. The low understanding of student concepts is due to the inability of students to interpret mathematical equations, and how to operate these equations in solving problems. The students' concepts understanding correlated with the students' basic concept of the basic concepts as required concepts, daily conception, multirepresentations (especially mathematical representation), and the students' intuition. Besides, it can be caused by the traditional learning process has not made students understand the concept well.

### RESUMO

A beta-talassemia é um grupo heterogêneo de doenças hereditárias do sangue caracterizadas por defeitos na síntese das cadeias  $\beta$  da hemoglobina, resultando em fenótipos variáveis que variam de anemia grave a indivíduos clinicamente assintomáticos. Este estudo tem como objetivo avaliar os níveis séricos de PTH, vitamina D, cálcio, fósforo, fosfatase alcalina e magnésio nos principais pacientes com  $\beta$ -talassemia. Um total de 50 (30 homens e 20 mulheres) pacientes com  $\beta$ -talassemia maior com idades entre 11 e 16 anos e um número igual de adolescentes saudáveis pareados por sexo como grupo controle foram incluídos neste estudo. Um total de 52% dos pacientes residia em área urbana e não houve diferença significativa entre os pacientes e o grupo controle em relação à residência. Pacientes do sexo masculino apresentaram baixos níveis estatisticamente significativos ( $P < 0,05$ ) de PTH sérico, vitamina D e níveis de cálcio, mas os níveis séricos médios de fósforo e fosfatase alcalina foram significativamente mais altos ( $P < 0,05$ ) quando comparados ao grupo controle masculino. No entanto, as pacientes do sexo feminino apresentaram nível médio de PTH sérico baixo, mas sem significância estatística ( $P > 0,05$ ), enquanto os níveis de vitamina D e cálcio foram altamente significativos ( $P < 0,05$ ). Os níveis de fósforo e ALP aumentaram significativamente ( $P < 0,05$ ) quando comparados aos controles femininos. Em relação ao grupo principal da  $\beta$ -talassemia, o presente estudo mostrou que pacientes do sexo masculino apresentaram níveis elevados não significativos ( $P > 0,05$ ) de PTH, cálcio, fósforo e ALP. Por outro lado, o nível de vitamina D não foi significativamente ( $P > 0,05$ ) baixo em pacientes do sexo masculino em comparação com pacientes do sexo feminino. O nível sérico médio de PTH teve uma correlação negativa com fósforo, mas teve uma associação positiva com vitamina D, cálcio, ALP e magnésio. Em conclusão, esse estudo demonstrou que os principais pacientes com  $\beta$ -talassemia têm um perfil ósseo metabólico bioquímico marcadamente perturbado. Também é recomendado o monitoramento regular do PTH e do perfil mineral bioquímico.

**Palavras-chave:**  $\beta$ -talassemia maior, PTH, marcadores ósseos metabólicos.

### ABSTRACT

Beta-thalassemia is a heterogeneous group of hereditary blood disorders characterized by defects in the synthesis of the  $\beta$ - chains of hemoglobin, resulting in variable phenotypes ranging from severe anemia to clinically asymptomatic individuals. This study aims to assess the serum PTH, vitamin D, calcium, phosphorus, alkaline phosphatase, and magnesium levels in  $\beta$ -thalassemia major patients. A total of 50 (30 male and 20 female) patients with  $\beta$ -thalassemia major with ages range 11- 16 years and an equal number of sex-matched healthy adolescents as a control group were included in this study. A total of 52% of patients were lived in an urban area, and there was no significant difference between patients and the control group regarding residency. Male patients showed low statistically significant ( $P < 0.05$ ) mean serum PTH, vitamin D, and calcium levels, but mean serum phosphorus and alkaline phosphatase levels were significantly higher ( $P < 0.05$ ) as compared to the male control group. However, female patients had low, but without statistical significant ( $P > 0.05$ ) mean serum PTH level, whereas vitamin D and calcium levels were highly significant ( $P < 0.05$ ) reduced. The phosphorus and ALP levels were highly significantly ( $P < 0.05$ ) increased as compared to female controls. Regarding  $\beta$ -thalassemia major group, the current study showed male patients had non-significant ( $P > 0.05$ ) higher levels of PTH, calcium, phosphorus, and ALP. In contrast, vitamin D level was non-significantly ( $P > 0.05$ ) low in male patients as compared

to female patients. Mean serum level of PTH had a negative correlation with phosphorus, but it had a positive association with vitamin D, calcium, ALP, and magnesium. In conclusion, this study demonstrated that  $\beta$ -thalassemia major patients have a markedly deranged biochemical metabolic bone profile. Regular monitoring of PTH and biochemical mineral profile is also recommended.

**Keywords:**  $\beta$ -thalassemia major, PTH, Metabolic Bone Markers.

## المخلص

بيتا فقر دم البحر الابيض المتوسط (الثلاسيميا) هي مجموعة غير متجانسة من اضطرابات الدم الوراثية تتميز بخلل في تخليق سلاسل بيتا في الهيموغلوبين، مما يؤدي الى انماط ظاهرية متغيرة تتراوح بين فقر الدم الشديد الى بدون اعراض مرضية عند الافراد. تهدف الدراسة الى تقييم مستويات هرمون جار الدرقية، فيتامين D، الكالسيوم، الفسفور، أنزيم الفوسفاتيز القاعدي والمغنسيوم في مصل الدم لمرضى بيتا ثلاسيميا الكبرى. شملت الدراسة 50 مريضاً (30 ذكر و 20 أنثى) مصابين بمرض بيتا ثلاسيميا الكبرى والذين تراوحت اعمارهم من 11 – 16 سنة، وعدد متساو من المراهقين الاصحاء المطابقين للجنس كمجموعة ضابطة في هذه الدراسة. يسكن 52% من المرضى في المناطق الحضرية ولم يلاحظ اختلافات معنوية بين المرضى ومجموعة السيطرة فيما يتعلق بمنطقة الإقامة. المرضى الذكور لوحظ لديهم انخفاض معنوي ( $p < 0.05$ ) في مستويات هرمون جار الدرقية، فيتامين D والكالسيوم، ولكن مستويات الفسفور وأنزيم الفوسفاتيز القاعدي مرتفعة معنويًا ( $p < 0.05$ ) بالمقارنة مع المجموعة الضابطة من الذكور. ومع ذلك، هرمون جار الدرقية انخفض لدى المرضى من الإناث لكن لم يصل الى مستوى المعنوية ( $p > 0.05$ )، بينما مستوى فيتامين D والكالسيوم انخفض معنويًا ( $P < 0.05$ )، مستويات الفسفور وأنزيم الفوسفاتيز ارتفعت معنويًا ( $p < 0.05$ ) بالمقارنة مع المجموعة الضابطة من الإناث. فيما يتعلق بمجموعة مرضى فقر دم البحر الابيض المتوسط (الثلاسيميا) الكبرى، بينت الدراسة الحالية ان المرضى من الذكور لديهم مستويات مرتفعة غير معنوية ( $p > 0.05$ ) من هرمون جار الدرقية، الكالسيوم، الفسفور وأنزيم الفوسفاتيز القاعدي ومستوى منخفض غير معنوي ( $p > 0.05$ ) من فيتامين D عند مقارنتهم مع المرضى من الإناث. أظهر هرمون جار الدرقية علاقة ارتباط سلبية مع الفسفور وعلاقة ارتباط موجبة مع فيتامين D، الكالسيوم، أنزيم الفوسفاتيز القاعدي والمغنسيوم. في الختام، أثبتت هذه الدراسة ان مرضى فقر دم البحر الابيض المتوسط (الثلاسيميا) الكبرى لديهم اضطراب بشكل ملحوظ في صورة العظام الايضية والكيموحيوية. توصي الدراسة الحالية بالمراقبة المنتظمة لمستوى هرمون جار الدرقية ومعايير العظام الكيوكيوية.

**الكلمات المفتاحية:** بيتا ثلاسيميا الكبرى، هرمون جار الدرقية، معايير العظم الايضية.

## 1. INTRODUCTION:

Beta-thalassemia is a heterogeneous group of hereditary blood disorders characterized by defects in the synthesis of the  $\beta$ - chains of hemoglobin, resulting in variable phenotypes ranging from severe anemia to clinically asymptomatic individuals. It has been estimated that about 1.5% of the global population (80 to 90 million people) are carriers of  $\beta$ - thalassemia, with about 60,000 symptomatic individuals born annually, the vast majority in the developing world (Galanello and Origa, 2010). In Iraq, the prevalence of thalassemia syndrome is 37.1/100.000 inhabitants, and  $\beta$ -thalassemia major represents 73.9% of all types of thalassemia (Kadhim *et al.*, 2017).  $\beta$ -thalassemia major is more severe transfusion-dependent anemia result from homozygosity or compound heterozygosity for a mutant  $\beta$ - globin gene and, occasionally, from heterozygosity for dominant mutations (Cao and Galanello, 2010; Olivieri, 1999).

The combination of transfusion and chelation therapy has dramatically extended the life expectancy of  $\beta$ -thalassemia major patients but is complicated by subsequent iron overload resulting in a high incidence of endocrine complication in children, adolescents, and young adults (Shamshirsaz *et al.*, 2003). Endocrine and metabolic bone disorders that are caused by repeated blood transfusions are of higher importance in  $\beta$ -thalassemia major patients. They are the second leading cause of mortality, after heart disorders, in these individuals (Chahkandi *et al.*, 2017).

Disturbance of calcium and phosphorus hemostasis due to parathyroid dysfunction, as well as metabolic bone diseases with various skeletal

complications including osteopenia, osteoporosis, scoliosis, rickets, spinal deformities, and spontaneous fractures, are a significant cause of morbidity and regularly reported in transfusion-dependent  $\beta$ -thalassemia major patients (Saboor *et al.*, 2017; Salama *et al.*, 2006). These complications are mainly due to repeated blood transfusion results in citrate toxicity and iron overload with deposition in parathyroid cells and tissue fibrosis, and chronic anemia (Galanello and Origa, 2010; Hamidi, 2016).

Bone turnover is assessed with several specific and sensitive serological markers, and serum PTH, calcium, phosphorous, alkaline phosphatase, vitamin D, and magnesium are characteristically altered with bone impairment in patients with thalassemia (Saboor *et al.*, 2017; Salama *et al.*, 2006; Khaleel, 2018).

This study aimed to assess the serum levels of PTH, vitamin D, calcium, phosphorus, alkaline phosphatase, and magnesium in  $\beta$ -thalassemia major patients.

## 2. MATERIALS AND METHODS:

Over six months, from 1<sup>st</sup> of December 2018 to the 31<sup>st</sup> of May 2019, a total 50 (30 male and 20 female) patients with  $\beta$ - thalassemia major with ages range between 11 to 16 years attended Misan Thalassemia Center along with 50 age and sex-matched healthy adolescents as control group were included in this case control study. Informed consent was obtained from parents or guardians of patients, and the Ethical Committee approved this study protocol at the College of Medicine, Misan University, Iraq. The diagnosis of  $\beta$ -thalassemia major was based on clinical history and examination in addition to the usual hematological data

(complete blood count, and Hb electrophoresis). The cases and control individuals were investigated for serum PTH, vitamin D, calcium, phosphorus, alkaline phosphatase, and magnesium levels. The assay principle for PTH based on competitive radioimmunoassay (RIA) (Cavalier *et al.*, 2015), combines an enzyme immunoassay sandwich method with a final fluorescent detection Enzyme Linked Fluorescent Assay (ELFA) was used for serum vitamin D measurement (Holick, 2007), serum calcium was determined by colorimetric method using methylmol blue indicator (Finley and Tietz, 1996), serum phosphorus level was determined by ammonium molybdate end point method (Drewes, 1972), ALP was also measured by colorimetric method using p-nitrophenylphosphate (Belfield and Goldberg, 1971), while spectrophotometric determination employing Calmagite was used to measured serum magnesium (Ingman and Ringbom, 1966).

Statistical analyses were reports as mean estimation  $\pm$  standard error, t test, and correlation using Statistical Package for Social Science (SPSS) version 23 for windows. Comparison of categorical data was carried by Chi-square test. *P* value of  $<0.05$  was considered as statistically significant.

### 3. RESULTS AND DISCUSSION:

A total 50 patients consisted of 30 (60%) male and 20 (40%) female  $\beta$ -thalassemia major patients and 50 healthy children matched for age and sex were studied as control group were enrolled in this study, see Table 1. In present study (52%, 26 patients) of thalassemia major patients lived in urban areas, while (38%, 19 patients) of control individuals were lived in rural area, and there was no significant difference between control and patients group regarding residency (*P* value 0.31), as shown in Table 2.

Regarding biochemical bone markers, data analysis showed that male patients have a highly significant ( $p < 0.05$ ) low serum PTH ( $35.01 \pm 5.19$  pg/ml), vitamin D ( $12.22 \pm 0.67$  ng/ml), and calcium ( $7.90 \pm 0.19$  mg/dL) levels in comparison to male control subjects ( $74.76 \pm 7.30$  pg/ml,  $54.30 \pm 4.69$  ng/ml, and  $9.84 \pm 0.23$  mg/dL respectively), but serum phosphorous ( $4.97 \pm 0.32$  mg/dL) and ALP ( $212.20 \pm 19.40$  U/L) were highly statistically significant ( $p < 0.05$ ) increased in male patients compared with male control ( $1.96 \pm 0.14$  mg/dL and  $83.62 \pm 7.11$  U/L respectively), also serum magnesium ( $2.18 \pm 0.38$  mg/dL) was increased but without statistical significant (*P* value=0.386) in male patients compared with control ( $1.83 \pm 0.09$  mg/dL), see Table 3.

In comparison female patients with female control results revealed that serum PTH level ( $31.39 \pm 5.69$  pg/ml) decreased without statistical significant (*P* value=0.549), but vitamin D ( $12.70 \pm 0.84$  ng/ml) and calcium ( $7.55 \pm 0.23$  mg/dL) levels were highly significant ( $p < 0.05$ ) decreased in patients compared with control females ( $40.38 \pm 4.66$  ng/ml and  $9.59 \pm 0.24$  mg/dL). Phosphorus ( $4.61 \pm 0.52$  mg/dL),

ALP ( $210.30 \pm 33.54$  U/L), and magnesium ( $2.04 \pm 0.36$  mg/dL) levels were measured higher. Still, only phosphorus level and ALP were highly significant ( $P < 0.05$ ) in female patients in comparison to the female control group ( $2.75 \pm 0.21$  mg/dL,  $91.36 \pm 4.55$  U/L, and  $1.76 \pm 0.12$  mg/dL respectively), as shown in Table 3.

Table 4, demonstrated that the serum levels of bone metabolic biochemical markers in male  $\beta$ -thalassemia major patients group including PTH ( $35.01 \pm 5.19$  pg/ml), calcium ( $7.90 \pm 0.19$  mg/dL), phosphorus ( $4.97 \pm 0.32$  mg/dL), ALP ( $212.20 \pm 19.40$  U/L), and magnesium ( $2.18 \pm 0.38$  mg/dL) were measured higher than in female patients ( $31.39 \pm 5.69$  pg/ml,  $7.55 \pm 0.23$  mg/dL,  $4.61 \pm 0.52$  mg/dL,  $210.30 \pm 33.54$  U/L, and  $2.04 \pm 0.36$  mg/dL respectively), but without significant difference, while vitamin D levels in male ( $12.22 \pm 0.67$  ng/ml) was lower without statistical significant difference than that in female patients ( $12.70 \pm 0.84$  ng/ml).

The results showed that the level of PTH had a negative correlation with phosphorus (-0.137), while it had a positive correlation with vitamin D (0.205), calcium (0.111), ALP (0.097) and magnesium (0.091). Vitamin D had an inverse correlation with phosphorus (-0.147) but is positively correlated with ALP (0.060), and magnesium (0.238), and significantly positive ( $P < 0.05$ ) with calcium (0.287). While calcium in our study results reported a negative correlation with ALP (-0.091) and a highly significant negative correlation with phosphorus (-0.583), but it had a highly significant positive ( $P < 0.01$ ) with magnesium (0.430). The level of phosphorus had an inverse correlation with magnesium level (-0.028), but it had a positive correlation with ALP (0.019) in our patient's results. Lastly, the level of serum ALP in our study showed a positive correlation with the level of serum magnesium (0.073) (Table 5).

In this study, 52% of  $\beta$ -thalassemia major patients lived in an urban area, and there was no significant difference between patients and the control group regarding residency. In agreement with our findings, Al-Ali and Faraj (2016) observed the incidence of  $\beta$ -thalassemia was significantly unchanged between the urban and rural populations, and so a study designed by Qurat-ul-Ain *et al.*, (2011) found the incidence of  $\beta$ -thalassemia was significantly higher in urban population than rural. In contrast, Tunç *et al.*, (2002) noticed the low frequency of  $\beta$ -thalassemia in the city center than in neighboring areas. The findings might be due to the same rate of consanguineous marriages among our population wherever they live, lack of effective prevention programs and poor legislation in our governorate.

Analysis of study results demonstrated that male patients in  $\beta$ -thalassemia major group have low statistically significant mean serum PTH, vitamin D, and calcium levels, but mean serum phosphorus and alkaline phosphatase levels significantly higher as compared to the male control group. However, in comparison to female  $\beta$ -thalassemia major patients with female control individuals, we observed low but without statistically significant ( $P < 0.05$ ) serum PTH

level. In contrast, vitamin D and calcium levels were highly significantly reduced, but phosphorus and ALP levels were highly significantly increased. Regarding  $\beta$ -thalassemia major group, the current study show male patients have non-significant higher levels of PTH, calcium, phosphorus, and ALP. In contrast, vitamin D level was non-significantly low in male patients as compared to female patients.

In agreement with our results, De Sanctis *et al.*, (1992) and Aleem *et al.* (2000) observed low PTH among  $\beta$ -thalassemia major patients. Low, PTH level among our patients is mainly due to the involvement of the parathyroid gland by iron overload, as well as its oxidative damage. Gutteridge and Halliwell (1998) and Goyal *et al.*, (2010) mentioned that parathyroid gland involvement by iron overload occurs particularly after ten years of age in  $\beta$ -thalassemia major patients, and a number of possible mechanisms have been described to be responsible for the damage of parathyroid glands through iron overload, which includes free radical formation and lipid peroxidation resulting in mitochondrial, lysosomal and sarcolemmal membrane damage. Also, Aleem *et al.*, (2000) found that parathyroid gland dysfunction in  $\beta$ -thalassemia major with iron overload is due to chelation therapy.

Parathyroid hormone is essential in calcium and phosphorus hemostasis and also plays a role in the conversion of vitamin D to its active form (1, 25 dihydroxycholecalciferol) in the kidney. A decrease in extracellular calcium concentrations or an increase in phosphorus concentrations leads to a PTH release from the parathyroid gland, which in turn increases renal reabsorption of calcium, renal activation of vitamin D, urinary phosphorus excretion, and bone resorption. In turn, vitamin D increases intestinal absorption and renal reabsorption of calcium and phosphorus (Penido and Alon, 2012; Kliegman, 2020). Documented abnormalities in PTH and biochemical metabolic bone markers values have been observed among  $\beta$ -thalassemia major (Hamidi, 2016; Dejkhamron *et al.*, 2018).

In agreement with our findings, Shetty and Shenoy, (2014), in their case-control study, found a significant decrease in serum PTH, and calcium, but significant increase in serum phosphorus and ALP in  $\beta$ -thalassemia major patients when compared to control. However, Goyal *et al.*, (2010) noticed serum PTH and serum calcium significantly reduced in  $\beta$ -thalassemia major patients that are similar to our results. Still, their serum ALP and phosphorus were not significantly altered when compared to the respective mean values for the control group. Also, Anju and Jain (2017) found serum calcium level was statistically significantly low, whereas serum phosphorus had no significant difference as compared  $\beta$ -thalassemia major patients to the control group. In contrast to our findings, Agrawal *et al.* (2016) observed that mean serum PTH was significantly higher and so calcium level but without significant difference, while phosphorus level was non-significantly lower in thalassemia patients compared to control. However, vitamin D value in their study is in agreement with our results was significantly lower in

patients compared to the control group. Still, there was no significant correlation found between vitamin D level and sex. In contrast, in our study, we found a significantly reduced level of vitamin D in male and female patients group compared to male and female control groups. However, in another study by Aggarwal *et al.*, (2018) found significant low vitamin D levels, despite serum PTH levels were not significantly different between cases and controls, while the serum level of calcium was found in the normal range in both groups, although the phosphorus and ALP levels were found to be significantly high in cases in comparison to controls.

The lower serum levels of vitamin D among  $\beta$ -thalassemia major patients can be due to decreased serum PTH level in our patients as a result of parathyroid gland involvement by iron overload. (Penido and Alon, 2012) documented PTH is one of the strongest stimulators of 1, 25 (OH)<sub>2</sub> D<sub>3</sub> production by increasing proximal tubular expression of 25(OH) D 1 $\alpha$ -hydroxylase, resulting in increased production of 1, 25(OH)<sub>2</sub> D<sub>3</sub>. Moreover, Soliman *et al.*, (2013) mentioned that both defective synthesis of 25 (OH) vitamin D and/ or hypoparathyroidism had been described in  $\beta$ -thalassemia major patients.

Our results were consistent with that of (Khaleel *et al.*, 2018; Ridha *et al.*, 2018) when they observed serum magnesium level was significantly higher in patients than normal control. At variance with our findings, Arcasoy and Cavdar (1975) and Fahmy *et al.*, (2019) observed a normal serum magnesium level in  $\beta$ -thalassemia patients, while Al-Samarrai *et al.*, (2008) and Nafady *et al.*, (2018) in their study showed that serum magnesium level was significantly lower in patients than the healthy control group. Hyman *et al.*, (1980) had been speculated that hypomagnesemia could be due to chelation by citrate in chronically transfused patients, or could just be a consequence of the cellular iron overload, but, Genc *et al.*, (2016) observed that level of magnesium had no significant difference between controls and patients with  $\beta$ -thalassemia major regardless type of chelating therapies. The finding of serum magnesium in our thalassemia patients may result from diet, chelation therapies, bone involvement (as 50% of total body magnesium resides in the bone), an increased rate of hemolysis among our patients (as magnesium is one of the major intracellular ions). In our study PTH had no significant correlation with calcium and phosphorus; that's similar to El-Deen *et al.*, (2014) observation.

In agreement with our results (Ridha *et al.*, 2018) noticed vitamin D had a significant correlation with calcium and ALP, while no significant association between PTH with the vitamin D, calcium, phosphorus, ALP, and magnesium.

#### 4. CONCLUSIONS:

There was no significant difference between control and  $\beta$ -thalassemia major patients groups regarding residency.  $\beta$ -thalassemia major patients

have markedly deranged biochemical metabolic bone markers. Male  $\beta$ -thalassemia major patients have highly significant decreased levels of serum PTH, vitamin D, and calcium. While serum phosphorous and ALP was a highly statistically significant increase in male patients compared with control. Female patients have highly significant decreased serum vitamin D and calcium levels, but phosphorus and ALP levels were highly significant in comparison to control. Regular monitoring of PTH and biochemical mineral profiles, as well as nutritional support and calcium/vitamin D supplementation, are highly recommended for these patients.

## 5. ACKNOWLEDGEMENTS:

Much obliged to Dr. Assad Yahia, Muntaha Yacoub, and Dr. Hummod Madhi for their assistance in performing the statistical analysis.

#### RESUMO

Um experimento foi conduzido para melhorar o desempenho das sementes de nabo sob condições de estresse de salinidade. O impacto da priming com uma dosagem otimizada (5 g/l) de KCl e NaCl foi avaliado para aumentar o vigor das mudas e a tolerância ao estresse salino em mudas de nabo. Sementes preparadas com (5 g/l) de soluções de KCl e NaCl foram examinadas em diferentes níveis de salinidade (0, 50, 100, 150, 200) mM de NaCl em relação ao estágio inicial de crescimento. Os dados foram analisados no Windows SPSS versão 23 (ANOVA de uma via  $p < 0,05$ ) para determinar a diferença significativa entre os tratamentos e os teste de Duncan,  $p < 0,05$  para comparação das médias. Os resultados mostraram que o priming com KCl e NaCl foi eficaz na redução dos efeitos adversos da salinidade. Um aumento significativo ( $P < 0,05$ ) na porcentagem de germinação, vigor das sementes, comprimento do hipocótilo e radícula, tolerância ao sal e peso seco das mudas de semente que iniciaram com (5 g/l) de KCl e NaCl em comparação com as sementes não preparadas foi gravado. Por outro lado, neste experimento, concluiu-se que se descobriu que o priming de sementes com KCl e NaCl era um melhor tratamento, especialmente na alta concentração de sais em comparação com as sementes não preparadas em caso de nabo para aumentar o vigor das sementes. e crescimento de plântulas sob condições estressantes ao sal.

**Palavras-chave:** *germinação, plântulas, nabo, preparação de sementes, sal.*

#### ABSTRACT

An experiment was conducted to enhance the turnip seed performance under salinity stress conditions. The impact of priming with an optimized dosage (5 g/l) of KCl and NaCl had been evaluated for enhancing seedling vigor and salt stress tolerance in seedlings of the turnip. Seeds prepared with (5 g/l) of KCl and NaCl solutions were examined at different salinity levels (0, 50, 100, 150, 200)mM of NaCl concerning the early growth stage. The data were analyzed using SPSS windows version 23 (one way ANOVA  $p \leq 0.05$ ) to determine the significant difference between treatments and followed Duncan test,  $p < 0.05$  for means comparison. The results have shown that priming with KCl and NaCl were effective in reducing the adverse effects of salinity. A significant ( $P < 0.05$ ) increase in germination percentage, seed vigor, hypocotyl and radicle length, salt tolerance, and dry weight of the seedlings of seed that priming with (5 g/l) of KCl and NaCl compared to non-primed seeds was recorded. On the other hand, In this experiment, it was concluded that seed priming with KCl and NaCl had been discovered to be better treatment, especially in the high concentration of salts as compared to non-primed seeds in case of turnip for rising the seeds vigor and seedling growth under salt-stressed conditions.

**Keywords:** *germination, seedling, turnip, seed priming, salt.*

#### المخلص:

أجريت تجربة لتحسين أداء بذور اللفت تحت ظروف إجهاد الملوحة. تم تقييم تأثير التحضير بجرعة محسنة (5 جم / لتر) من (KCl) و (NaCl) لتعزيز قوة الشتلات وتحمل الإجهاد الملحي في شتلات اللفت. تم فحص البذور المحضرة بمحلول (5 جم / لتر) من محلول كلوريد البوتاسيوم و كلوريد الصوديوم

بمستويات ملوحة مختلفة (0، 50، 100، 150، 200) ملي مولار من كلوريد الصوديوم فيما يتعلق بمرحلة النمو المبكر. تم تحليل البيانات باستخدام نافذة الحزمة الإحصائية للعلوم الاجتماعية (SPSS) الإصدار 23 (تحليل التباين باتجاه واحد ANOVA قيمة  $p \leq 0.05$ ) لتحديد الفروق المعنوية بين المعاملات والمتبع بأختبار دنكن ذو المدى المتعدد، قيمة  $p < 0.05$  للمقارنة. أوضحت النتائج أن الإعداد باستخدام كلوريد البوتاسيوم و كلوريد الصوديوم كان فعالاً في تقليل التأثيرات السلبية للملوحة. تم تسجيل زيادة معنوية ( $P < 0.05$ ) في نسبة الإنبات وقوة البذور وطول السويق وطول الجذير وتحمل الملح والوزن الجاف لشتلات البذور التي تم معاملة بـ (5 جم / لتر) من KCl و NaCl مقارنة بالبذور غير المعاملة. من ناحية أخرى، في هذه التجربة، تم الاستنتاج إلى أن إعداد البذور باستخدام KCl و NaCl قد تم اكتشافه على أنه أفضل معاملة، خاصة في التراكيز العالية للأملاح بالمقارنة مع البذور غير المعاملة في حالة اللفت لتحسين قوة البذور و نمو الشتلات تحت ظروف الإجهاد الملحي.

**الكلمات المفتاحية:** الإنبات، الشتلات، اللفت، تحضير البذور، الملح.

## 1. INTRODUCTION:

Turnip (*Brassica rapa*) belongs to family Cruciferae, and It is one of the most important dicotyledonous, cross-pollinated, and cool-season vegetable crops grown both for its enlarged roots and for the foliage (Pink, 1993). *Brassica* species are distinguished by their immense intraspecific diversity, exemplified by leafy plants, oilseeds, and crops with extended inflorescences and above-ground storage organs (Liu *et al.*, 2019). Soil salinity is one of the abiotic adversely influence on seed germination, seedling establishment, and efficiency of numerous harvests by creating an osmotic potential outside the seed inhibiting the absorption of water, or by the toxic effect (Mustafa *et al.*, 2017; Bose *et al.*, 2017). Osmotic and saline stresses are in charge of the inhibition and declines of seed germination and plant development (Yohannes and Abraha, 2013).

The water absorption decreases during the imbibition stage, and salinity leads to excessive absorption of toxic ions by the seed (Abraha and Yohannes, 2013; Murillo-Amador *et al.*, 2002). From the beginning of agriculture, the man established contact with seed physiology and realized that many seeds do not germinate easily and uniformly. The capacity of seemingly (dead seed) to regenerate and grow a viable young and healthy seedling after germination had been fascinated by the ancient civilization, therefore, the scientists for decades trying to figure out several methods of seed priming in order to activate seeds and alleviate environmental stresses and common technique its water-based priming techniques, which is a pre-sowing treatment that partially hydrates seeds without allowing emergence (Evenari, 1984; Chen and Arora, 2011).

Seed priming is a pre-germination seed treatment that leads to a physiological state that enables the seed to germinate more efficiently mean seeds are held at water potential that permits imbibition but prevents radicle extensions (Ashraf and Foolad, 2005; Gupta *et al.*, 2008;

Lutts *et al.*, 2016). Seed priming enhances seed performance by rapid and uniform germination, healthy and vigor seedlings, which resulted in faster and better germination and development in various harvests, this also helps seedlings to grow in stressed conditions (Mohammadi, 2009; Safdar *et al.*, 2019). Priming-induced increase in germination may be associated with a change in plant hormone biosynthesis and signaling. Priming has been reported to increase the gibberellins (GA)/abscisic acid (ABA) ratio, and this may be a direct consequence of a priming impact in gene expression pattern (El-Araby *et al.*, 2006; Schwember and Bradford, 2010). Several variables influence the priming performance and are highly on handled plant species and the priming technique selected. Physical and chemical factors such as osmotic and water capacity, priming agent, length, temperature, presence or absence of light, aeration and seed condition also affect the priming performance and decide the time and rate of germination, seedling vigor, and further plant growth (Hussain *et al.*, 2006; Varier, 2010).

Osmopriming means soaking seeds with low water content in an osmotic solution, rather than pure water. Because of the low water capacity of osmotic solutions, water enters seed gradually, which allows gradual impregnation of seed and activation of early germination phases but prevents radicular protrusion (Girolamo and Barbanti, 2012).

However, values of water potential, together with the duration of the priming treatment, should always be adjusted to species, cultivar, and sometimes seed lot. Different compounds are used in osmopriming procedures, including polyethylene glycol (PEG), mannitol, sorbitol, glycerol, and inorganic salts such as NaCl, KCl, KNO<sub>3</sub>, K<sub>3</sub>PO<sub>4</sub>, KH<sub>2</sub>PO<sub>4</sub>, MgSO<sub>4</sub>, and CaCl<sub>2</sub>. Priming with salt solutions is often referred to as "halopriming" (Yacoubi *et al.*, 2013).

Seed priming with various salts, especially KCl and NaCl, has appeared to improve the germination and development of numerous

harvests under stressed conditions (Naz *et al.*, 2014). The present study was carried out to investigate the impact of KCl and NaCl priming on germinations of seeds and seedling growth of turnip (*Brassica rapa rapa*) under salinity conditions.

## 2. MATERIALS AND METHODS:

### 2.1. Experiment site

In order to determine the effects of different salinity levels and Osmo priming on germination and seedling growth, the experiment was carried out in botany Laboratory, Department of Biology, University of Misan. The laboratory was approximately at 21°C, and the experiment was carried out inside safety cabins, the materials were used seeds, deionized distilled water, 5 g/l iter of NaCl and KCl, (50,100,150, 200mM) of NaCl, 70% ethanol, 5% Na<sub>2</sub>HCl, the equipment was used Petri dishes, filter paper, and parafilm.

### 2.2. Seed sterilization and soaking

Healthy turnip seeds were surface sterilized with 70% ethanol for 30 seconds and then with 5% sodium hypochlorite (Na<sub>2</sub>HCl) solution for 20 min and then thoroughly washed three times with sterilized distilled water (sterilized by using autoclave). Subsequently, the seeds were soaking with 5 g/l KCl and NaCl solution separately for 24 hours at 21°C. After priming. The seeds were washed with sterilized distilled water after priming and dried at room temperature on filter paper for 24 h to their original moisture level, utilizing sensor balance before being used in germination tests. (Yohannes and Abraha, 2013).

### 2.3. Experimental design

The study was carried out in November/2019. A complete random design (CRD) used to study the effect of seed priming on germination and seedling growth of turnip under salt stress. This part of the experiment was carried out in the laboratory in 45 Petri dishes, that is, 15 for KCl, 15 for NaCl primed seeds, and 15 for unprimed (control) seeds and repeated thrice. Primed and unprimed seeds were placed in 9 cm diameter Petri dishes on two layers of filter papers (Whatman No. 1). 15<sup>th</sup> seeds were placed in each Petri dishes were containing 5 ml of five different saline solutions (0, 50, 100, 150, 200 mM of NaCl). The Petri dishes were closed with par-film to prevent evaporation and kept in

the growth chamber at 21 ± 2°C. The experiment was conducted in a completely randomized design with six replications and 15<sup>th</sup> seeds per replicate. Seed germination was recorded daily up to day ten after the start of the experiment. When the radicle emerges by around 2 mm in length, a seed was considered germinated (Mohammed and Nulit, 2019<sup>a</sup>). The length of the hypocotyl and radicle of seedling were measured by selecting three seedlings randomly from each Petri dish, the seedlings were dried at 60°C for 48 h and then weighed (Li, 2008; Oliveira *et al.*, 2019). Germination percentage (GP %) was calculated according to Equation 1 by (Kandil *et al.*, 2012).

$$GP\% = \frac{\text{Number of germinated seeds}}{\text{Total number of seeds sown}} \times 100 \quad (\text{Eq. 1})$$

Seed vigor was calculated according to (Gebremedhn and Berhanu, 2013) Equation 2, which is:

$$\text{Seed vigor} = \frac{(L1 + L2) \times \text{germination percentage}}{100} \quad (\text{Eq. 2})$$

whereas: L1= length of hypocotyls

L2= length of radical

### 2.4. Statistical analysis

Statistical analysis was performed using SPSS window version 23. One-way confidence-level variance analysis (ANOVA) (Naz, 2014),  $p \leq 0.05$  was performed to find the significance deference among treatments followed by Duncan's multiple range test (DMRT) at  $p \leq 0.05$  for mean comparison.

## 3. RESULTS AND DISCUSSION:

### 3.1. Germination percentage (GP %)

Figure 1 shows the impact of NaCl and KCl priming on turnip (GP %) at different saltiness concentrations, respectively, in 10 days. From both primed and unprimed seeds diminished significantly ( $P \leq 0.5$ ) with increasing NaCl salinity level. However, this reduction in (GP %) was lower for primed seeds compared to unprimed seeds. Salinity reduced germination percentage for more than half due to an increase in salinity level from 0 mM to 200 mM. A similar decrease in germination percentage has been

recorded with rising salt levels in turnip (Mohammed and Nulit, 2019a; Mohammed and Nulit, 2019b). Seed generally, increasing salinity causes a decrease in turnip germination; this might be due to the toxic effects of  $\text{Na}^+$  and  $\text{Cl}^-$  in the process of germination (Tobe *et al.*, 2004; Osman, 2018). It changes the imbibitions of water by seeds due to decline osmotic capacity of germination media (Ibrahim *et al.*, 2019), it causes toxicity which changes the activity of certain enzymes of DNA metabolism, changes the metabolism of protein, breaks down the hormonal balance, and reduce the usage of seed reserve food (Ashraf and McNeilly, 2004; Ashraf *et al.*, 2010). Primed seeds of turnip might have better competency for water absorption from the growing media that enabled metabolic activities in seeds during the germination process of a start much earlier than radical and hypocotyl appearance (Elouaer and Hannachi, 2012; Zaghdani, 2002).

Similarly, increased solubility of seed storage proteins such as the beta subunit of the globulin and enhanced antioxidative reduction in lipid peroxidation and activity in primed seeds facilitated germination (Patade *et al.*, 2009; Kazemi and Eskandari, 2012). According to Soeda *et al.* (2005), the faster germination was due to the synthesis of protein, DNA, and RNA during seeds priming. A high positive correlation between seed germination and the amount of total soluble protein, Tania *et al.* (2019), reported the increased germination ability and total protein in areas with low pollution levels of anthropogenic pressure in *Betula pendula* plant.

### 3.2. Turnip seedlings length

Shoot and root lengths are the essential factors in the plant for salt stress because roots absorb water due to direct contact with soil, and then shoots enable its supply in the whole plant. For this reason, shoot and root lengths provide important indications of a plant's response to salt stress (Dinnyeny, 2019). Figure (2) shows an increase in the concentration of salts caused the reduction in the early growth of turnip seedlings. The length of seedling (radicle+ hypocotyl) significantly declined with increasing salts concentration in both primed and un-primed seeds. However, this influence was more distinguished in radicle (Figure 3) and hypocotyl (Figure 4) lengths from unprimed seeds when compared to the primed ones. A similar study shows that the adverse impact of salinity on *Pisum sativum* was overcome by the application of potassium nutrient through seed priming with KCl (Naz *et al.*, 2014). Seedlings' growth was

affected by both osmotic and specific ionic of salinity (Nawaz *et al.*, 2010; Tabatabaei and Naghibalghora, 2014). Nasim *et al.* (2008) and Petropoulos *et al.* (2017) investigated that salinity inhibits the absorption of essential nutrients such as P and K, which could negatively affect seedlings growth. In this study, seed priming significantly improved turnip seedling growth at different salinity levels. The improvement in radicle and hypocotyl length in the primed seeds may be attributed to earlier germination induced by priming (Farooq *et al.*, 2005). During the period of priming, the embryo expands and compresses the endosperm, the compaction force of the embryo and the water activity on the walls of endosperm cell may alter the tissues to be flexible when dehydrated, Produce free space and facilitate rapid projection of root and seedlings after rehydration (Mohammadi, 2009; Yohannesu and Abraha, 2013).

### 3.3. Seed vigor

Seed vigor is the characteristics of seed that determine the level of activity and performance of seeds during germination and emergence of seedling under a wide range of field conditions. Seedlings of high-activity seeds are expected to develop more uniformly than seedlings of low-activity seeds (Talai and Sen-Mandi, 2010; Egli and Rucker, 2012). Figure (5) shows both primed with (NaCl or KCl) and unprimed seeds diminished significantly with increasing salinity levels. However, this reduction in vigor was lower for primed seeds compared to unprimed seeds. Similar past investigation on Canola (*Brassica napus* L.) and tomato (*Lycopersicon esculentum* Mill.) showed that seed priming significantly improved shoot and radicle length (Nawaz *et al.*, 2010).

### 3.4. Dry Biomass of turnip

Salinity treatments were applied on turnip showed a significant reduction in dry seedling biomass with the rise of stress level as compared with control in both unprimed and primed seeds (Figure 6). For primed seeds, dry biomass was higher than for unprimed ones at different levels of salinity stress. Mohammed and Nulit (2019a; 2019b) showed that salt stress decreases the weight of turnip seedling. They suggested that the decrease in growth of turnip seedling is due to ionic stress and osmotic stress of salts. By increasing salinity, the biomass of seedling decreased, which might be attributed to a decrease in the remobilization of the seed reserves from cotyledons to the embryonic axis

(Yohannes and Abraha, 2013). The factors that affected the growth rate of the embryonic axis also affected transfer from cotyledons to the embryonic axis and reserve remobilization (Sedghi *et al.*, 2010; Naz *et al.*, 2014). The efficiency of seed priming with KCl or NaCl in improving biomass weight under stressful conditions was also reported in sunflower, melon (Matias *et al.*, 2018; Oliveira *et al.*, 2019).

#### 4. CONCLUSIONS:

This investigation provided useful knowledge on seed priming using a NaCl and KCl. Turnip's primed and unprimed seeds have different responses to saline solutions, especially in high concentrations. Seed priming with NaCl and KCl overcame these adverse effects of salinity. This priming significantly improved the germination and seedling growth of these plants. In unprimed seeds, declines in germination percentage and seedling growth with rising salinity levels were more apparent than in the primed seeds. Pretreatment with NaCl and KCl lead to a substantial improvement in the percentage of germination seed vigor seedling radical length, hypocotyl seedling length, and dry seedling biomass. Therefore, this research highlighted the benefit of applying seed priming techniques in salty stressful environments to reduce the adverse effects of salinity stress on germination and early development of seedlings under controlled conditions. However, more work is required to assess crop production (NaCl and KCl) on vegetative growth and yield under field conditions.

**RESUMO**

O papel das gorduras na nutrição é determinado pelo seu alto teor calórico e participação na construção dos tecidos do corpo, juntamente com proteínas e carboidratos. A nutrição enriquecida é de grande importância no complexo de questões que determinam sua utilidade. Assim, a questão do efeito dos probióticos e sorventes na dieta do organismo animal tornou-se muito relevante. O objetivo do trabalho foi uma avaliação comparativa da composição e propriedades do tecido adiposo de carneiros, consumindo juntos e separadamente preparações com efeito de sorção e probiótico. Os estudos foram realizados em duas etapas. Na primeira, durante o experimento científico e econômico, 80 carneiros recém-nascidos cresceram e se desenvolveram até um ano de idade, seguidos pelo abate de três animais de cada grupo. Na segunda etapa, as amostras de gordura interna foram examinadas de acordo com vários indicadores. A análise sensorial revelou que todas as amostras internas de gordura atendiam aos requisitos estabelecidos, enquanto a cor e consistência das amostras experimentais melhoraram. O teor de matéria seca, incluindo gordura nas amostras experimentais de tecido adiposo, aumentou e a umidade diminuiu. Os parâmetros físicos e técnicos da gordura interna também mudaram no aspecto intergrupo. Na amostra controle, o número de iodo diminuiu e o número de saponificação, ponto de fluidez e ponto de fusão aumentaram. O cálculo do valor energético indica que, na primeira amostra, o indicador aumentou 0,08 MJ (0,23%); Grupo II - por 0,16 MJ (0,45%) e grupo III - por 0,25 MJ (0,70%). De acordo com a soma de ácidos graxos monoinsaturados, o grupo jovem III estava na liderança. O conteúdo de ácidos graxos poliinsaturados foi o oposto. A eficácia biológica das gorduras é determinada pela proporção que foi melhor nas amostras experimentais. Assim, a inclusão de aditivos forrageiros na dieta dos carneiros da raça Romanov ajuda a melhorar a qualidade das matérias-primas.

**ABSTRACT**

The role of fats in nutrition is determined by their high-calorie content and participation in the construction of body tissues, together with proteins and carbohydrates. Enriched nutrition is of great importance in the complex of issues that determine its usefulness. Thus, the question of the effect of probiotics and sorbents in the diet on the animal organism has become very relevant. The purpose of the work was a comparative assessment of the composition and properties of adipose tissue of rams, consuming together and separately preparations with sorption and probiotic effect. The studies were carried out in two stages. In the first, during the scientific and economic experiment, 80 newborn rams grew and developed up to a year of age, followed by the slaughter of three animals from each group. In the second stage, samples of internal fat were examined according to some indicators. Sensory analysis revealed that all internal fat samples met the established requirements, while the

color and consistency of the experimental samples improved. The dry matter content, including fat in the experimental samples of fat tissue, increased, and moisture decreased. The physical and technical parameters of internal fat also changed in the intergroup aspect. In the control sample, the iodine number decreased, and the saponification number, pour point, and melting point increased. Calculation of energy value indicates that in the first sample, the indicator increased by 0.08 MJ (0.23%); Group II – by 0.16 MJ (0.45%) and group III – by 0.25 MJ (0.70%). According to the sum of monounsaturated fatty acids, young group III was in the lead. The content of polyunsaturated fatty acids was the opposite. The biological effectiveness of fats is determined by the ratio that was better in the experimental samples. Thus, the inclusion of fodder additives in the diet of the rams of the Romanov breed helps to improve the quality of raw materials.

**Keywords:** *composition, internal fat, probiotic, Romanov breed, sorption additive*

## 1. INTRODUCTION:

Fats, including animal fats, are an essential component of food. The significance of fats consists, first of all, in their high energy value, since the caloric content of 1 g of fat is 9 kcal, which is more than two times exceeds the caloric content of proteins and carbohydrates. The biological value of animal fat lies in the presence of vitamins A, D, E, K and polyunsaturated fatty acids in it (Bagautdinov *et al.*, 2018; Creemers, Van Passel, and Vigani, 2019; Dementyev *et al.*, 2018; Khaziakhmetov *et al.*, 2018a, 2018b; Kick, Zering, and Classen, 2017; Lamanov *et al.*, 2020; Sharipova *et al.*, 2017a).

The global trend indicates that the consumption of fats and butter has quadrupled compared with the level recorded 50 years ago. This was due to an increase in population, an increase in fat intake, and a change in cooking methods (Aslanova, Derevitsckaya, and Dydikin, 2018; Igenbayev *et al.*, 2019; Mironova, Nigmatyanov, Radchenko, and Gizatova, 2019a; Okuskhanova *et al.*, 2019; Sydykova *et al.*, 2019).

In 1950, the number of animal fats on the market was only slightly lower than vegetable oils. In 1970, animal fats accounted for only a quarter, and currently – only 15% (Gavrilova *et al.*, 2019; Gubaidullin, Mironova, and Islamgulova, 2010; Kalasov, Andrienko, Galieva, and Kasimova, 2019; Kosilov, Gazeev, and Yuldashbaev, 2016; Mironova, Nigmatyanov, Grunina, Sepiashvili, and Strigulina, 2019; Shkilev, Gazeev, and Nikonova, 2011).

The UN Food and Agriculture Organization estimated the total mean energy intake from plant and animal sources to be around 3380 kcal in Europe and the US with the animal source energy intake accounting for 943 kcal (27.9%). In developing countries, a similar figure is 2,261 kcal, and 331 kcal (14.6%) of energy is supplied through animal feed. In countries with transition economies, which include Russia, the total energy

supply is 2,906 kcal, and 671 kcal (23.1%) comes from animal feed. In recent years, there has been an accumulation of critical knowledge about the predominance of vegetable fats in the human diet. A study of the role of individual fatty acids in biochemical transformations indicates that animal fats are necessary for the normal functioning of the body, and possible negative consequences are reduced or even eliminated by the presence of individual fatty acids or other biologically active substances (Kuzmicheva, 2013; Khaziev *et al.*, 2018; Obolentsev, 2018; World Health Organization, 2003; Ziyangirova, Mironova, Gazeev, Galieva, and Galieva, 2019).

By analyzing data from the FAO report, a specific food production concept has been outlined. The idea is a point aimed at expanding the use of biological resources, thereby diversifying the nutritional composition of foods to satisfy the physiological needs of the population (Tagirov *et al.*, 2018; World Health Organization, 2003).

One of the approaches to expanding the species diversity of raw materials in the conditions of the Southern Urals is the use of mutton. The volume of its production in the Russian Federation is not more than 3% of the total mass of raw meat. Even though the Volga Federal District is the leader in the number of sheep, the volume of output is much less than the needs of the domestic market. Therefore, the development of sheep breeding will allow, firstly, to partially eliminate the shortage of meat raw materials and secondly to expand the range of products, including those with new properties (Gabitov *et al.*, 2018; P. Kornienko, Yusupov, Eremanenko, and R. Kornienko, 2008; Ponomarenko, Grishina, and Bekturov, 2017; Traisov, Sultanova, Yuldashbayev, and Esengaliyev, 2014; Traisov *et al.*, 2015).

Besides, the development of the sheep industry allows, in addition to food products, which include milk and meat, to supply the light industry with raw materials, such as wool and sheepskin

(Bogolyubova, Korotky, Zenkin, Ryzhov, and Buryakov, 2017; Sharipova *et al.*, 2017b; V. Vorobyev, D. Vorobyev, Zakharkina, Polkovnichenko, and Safonov, 2019).

Russia is famous for its more than century-old history of breeding Romanov sheep with a meat-and-wool direction of productivity. A distinctive feature of this breed is its good adaptability to sharply continental climate conditions, unpretentiousness to feeds, fecundity, early maturity, and polyestricity. The resulting lamb is characterized by good taste, the absence of a specific taste, high biological, and low energy value (Bogolyubova *et al.*, 2017; Chernitskiy, Shabunin, Kuchmenko, and Safonov, 2019; Dvalishvili and Vinogradov, 2015).

Although the animals of the Romanov breed are unpretentious to the feeding conditions, they can still maximize the productive potential of the sheep with a full and balanced diet (Okuskhanova *et al.*, 2019; Sedykh *et al.*, 2018). It is recommended to enrich the diet with feed additives of sorption action and probiotic. Then the choice of the object of study is since fats, like protein components of meat, play an important role in human life, provided they are reasonably consumed. Meat is the main source of animal fats, which supply vitamins A and D to the body and contribute to their absorption (Zabelina and Lushnikov, 1999).

The optimal total norm of consumption of animal and vegetable fats in the diet is 100-150 g per day, while animal fats should account for 70-75 g, vegetable fats – 30 g. For the organization of the herodietic ration, this ratio should be at the level of 1:1 (Andrienko, 2018; Efimova and Antonenko, 2016).

It is known that the composition of fat is represented by carbon, hydrogen, and oxygen, and by the chemical structure, they are complex substances. The fat molecule contains glycerin and fatty acids, which are classified as saturated and unsaturated. The group of saturated lamb fatty acids is represented by palmitic, stearic, and unsaturated – by oleic acids. According to their properties, palmitic and stearic acids at 15-20 °C retain their hardness, and oleic acid is in liquid form. Stearic acid, which is part of lamb fat, undergoes melting at a temperature of 69.2 °C, and upon solidification, it crystallizes.

According to the organoleptic properties, lamb fat should have white matte color and a specific smell. It is important to note that the fat of

adult animals has a more saturated and dark color than the fat of young animals.

The studies of domestic and foreign scientists indicate that if the nutrients of the diet are not used as a building material, then they are transported and stored in the body in the form of a reserve – fat. Not only lipids but also unused nitrogenous substances and carbohydrates turn into fat (Gadiev *et al.*, 2019; Erochin *et al.*, 2013; Khabibullin *et al.*, 2019).

Sheep are characterized by having a certain sequence in the deposition of fat: first – on the internal organs (kidneys, intestines, stomach), then – at the root of the tail, on the lower back, brisket (subcutaneous) and between the muscles (intramuscular). Fat accumulated in animals, in many respects, affects the taste, appearance, and calorie content of meat (Andrienko, 2018).

The purpose of this study was to study the physicochemical parameters, as well as the fatty-acid balance of the internal sheep's fat, obtained from animals consuming various supplements.

## 2. MATERIALS AND METHODS:

The studies were carried out according to the thematic plan of Bashkir State Agrarian University No. 01860076873. To obtain fat raw materials at the initial stage in the conditions of the Republic of Bashkortostan, scientific and economic experience was organized on rams of the Romanov breed, which were divided into four groups of 20 animals each. The number of animals was selected, taking into account the possibility of ensuring the reliability of the data. Groups were formed according to the principle of analogs from among newborn lambs. Feeding the young of the control group consisted of giving the main diet adopted on the farm. The diet of animals from the experimental groups additionally included additives that were added at the rate of 0.10 g / kg of live weight. For the sheep of group I, a sorption additive was used, group II was probiotic, group III used both together. The experiment lasted until the animals reached the age of one year. To conduct the second stage of research with the aim of comparative studying the chemical composition of internal fat at 12 months of age, a control slaughter of three animals from each group was organized according to the All-Russian Institute for Animal Breeding method (1978).

Sensory assessment of fat was carried out by the organoleptic method, which is based on the perception of the senses – vision, smell, hearing,

touch, taste. Color and consistency were analyzed at a temperature of 15-20 °C, and the degree of transparency was established in the molten state of fat. To study the chemical composition of adipose tissue, an average sample was taken, and the All-Russian Institute for Animal Breeding method (1978) was applied. The mass fraction of moisture was determined according to State Standard 9793-74, the protein was established by the Kjeldahl total nitrogen determination method, the iodine number was determined by the Güble method, the melting point was determined by the capillary method, and the energy value was established by the Aleksandrov formula (1951); the amount of fatty acids – on a “Crystal-2000M” gas-liquid analytical chromatograph according to State Standard R-51.483-99.

The animals were kept according to the instructions and recommendations of Russian Regulations, 1987 (Order No.755 on 08/12/1977 the USSR Ministry of Health), as well as “The Guide for Care and Use of Laboratory Animals (Institute of Laboratory Animal Resources, Commission on Life Sciences, National Research Council, National Academy Press Washington, DC 1996)” (Institute of Laboratory Animal Resources, 1996; The USSR Ministry of Health, 1987). In the course of the research, efforts were made to minimize animal suffering and the least number of samples used.

The digital material obtained in the experiment was processed by the variation method of statistics Microsoft Office with determining the reliability of the difference at three levels of probability, according to Student.

### 3. RESULTS AND DISCUSSIONS:

The assessment of the quality of fat by organoleptic indicators showed that regardless of the type of additive used, all samples of internal fat met the established requirements (Table 1).

At the same time, some intergroup differences in the consistency of the samples are noted. In particular, the best consistency of fat is noted in the sample obtained from animals of groups I and II, which is characterized as dense. The introduction of feed additives into the diet positively affected the color of the product. The fat of the experimental samples was characterized by white color, without a clear yellowish tint, which meets the requirements of normative and technical documentation.

Because its constituent components

determine the quality of fat, a chemical analysis was carried out (Figure 1).

It was found that the highest solids content was observed in experimental samples of adipose tissue. So, the advantage of the rams of the first experimental group over the young ones of the control group was 0.30%; group II – 0.47%; group III 0.72%. A similar distribution between groups is also noted in the content of chemically pure fat. It is enough to note that the difference in favor of the experimental young rams of the I, II, and III groups was 0.20%; 0.39% and 0.60%. In all cases, in the lead were the rams consuming the tested additives together.

By a mass fraction of moisture, the intergroup difference was the opposite. In animals of the control group, the studied indicator increased by 0.23%; 0.47 and 0.69%, respectively. For a more accurate analysis of the influence of the feed additive on the qualitative characteristics of the fat of rams, physicochemical studies of internal fat were carried out (Table 2).

The previously established differences in the chemical composition of adipose tissue of different localization affected the energy value. In experimental samples of fat (I, II, III), compared with the baseline, the energy value of 1 kg fat increased by 0.08 MJ (0.23%), 0.16 MJ (0.45%), and 0.25 MJ (0.70%), respectively.

Saponification number is an indicator for determining the authenticity of fatty oils. Fats containing mainly triglycerides are analyzed by the average molecular weight of the fatty acids included in them. Moreover, fats rich in saturated acids have a high melting point, while unsaturated fats have a low melting point.

The introduction of test additives in the diet of animals contributed to the improvement of technological parameters of internal fat.

The results of the study indicate that the introduction of additives into the diet did not adversely affect the pour point of the internal fat of ram carcasses of all the samples studied. The intergroup differences in the value of the melting temperature and the Güble number were insignificant within the physiological norms.

In assessing the quality of fat, significant importance is given to the qualitative composition of fatty acids. In this regard, the fat-acid gas-chromatographic analysis of the triglycerides that make up the internal (omentum + perinephric) adipose tissue of sheep fat was carried out. The

analysis of these studies indicates an increase in the content of many saturated fatty acids in the experimental samples compared with the control (Table. 3). The superiority of young rams from I-III groups in the content of capric fatty acid over peers of the control group was 0.01–0.02%, myristic – 0.03-0.07%, palmitic – 0.06-0.08%, stearic – 0.05-0.06%. Among monounsaturated fatty acids, oleic predominates. The value of the studied indicator in young animals of the first experimental group was higher than in control by 0.04%, II – by 0.2%, III – by 0.21%.

The indicators of polyunsaturated arachinic and arachidonic fatty acids did not change and were in the range of 0.25-0.26% and 0.27%, respectively. The indices of linoleic fatty acid in rams of the first experimental group decreased by 0.06% compared to the control group, of the second experimental group – by 0.1%, the third experimental group – 0.03%; linolenic – by 0.05%; 0.03% and 0.03%, respectively. When analyzing the total mass fractions of the fatty acid content, certain intergroup differences are noted (Table 4).

According to the amount of monounsaturated fatty acids, young rams from group III were in the lead. Its superiority over control peers in terms of the studied indicator was 0.37%, over analogs of the first group – 0.09%, II – 0.33%. The content of polyunsaturated fatty acids was the opposite. It is enough to note that in young animals, this indicator was higher than in experienced peers of the I, II, and III groups – by 0.1%, 0.12%, and 0.06%, respectively.

It should be noted that the amount of saturated fatty acids was higher in animals consuming test supplements. So, they have this indicator increased by 0.14%, 0.16%, and 0.21%, compared with the control peers.

A comparative analysis of the ratio characterizing the biological effects of fats indicates a similar dynamics in young animals of all experimental groups. Thus, the introduction of sorption and probiotic additives into the diet of rams did not have a significant effect on the biological effectiveness of fats. However, there was a slight positive tendency in the experimental samples.

The search for measures to provide the population with full-fledged food products, due to the species diversity of raw materials, is a strategic task of the agricultural sector (Andreeva *et al.*, 2018; Andrienko, 2018; Filippova *et al.*, 2017; Gadiev *et al.*, 2019; Gubaidullin, Kanareykina, and

Timerbulatova, 2014; Khabibullin *et al.*, 2019; Khaziahmetov *et al.*, 2018; Kosilov, Nikonova, Wilver, and Kubatbekov, 2016; Zabelina and Lushnikov, 1999). It is proposed to intensify the sheep breeding industry by improving the feeding system of Romanov rams with subsequent analysis of the quality of the obtained raw materials. The organoleptic assessment revealed intergroup differences in the consistency of samples with the best characteristics, characterized by density, in samples I and II. In this case, the fat of the test samples was white, without a clear yellowish tint.

The chemical analysis of internal mutton fat revealed a decrease in the proportion of moisture (by 0.23-0.69%), an increase in the share of solids (by 0.30-0.72%), fat (by 0.20-0.60%) and therefore, the energy value of 1 kg of fat (0.08-0.25 MJ (0.23-0.70%) in experimental samples of adipose tissue.

The physical-technical properties of the fat of all the studied samples when sorption and probiotic additives were added to the diet of rams did not have a negative effect. At the same time, specific differences between the groups in connection with the use of different fodder backgrounds were insignificant and did not go beyond the normative.

The study of the qualitative composition of fatty acids revealed an increase in the proportion of some saturated fatty acids (capric, myristic, palmitic, stearic) in the experimental samples, compared with the control. Among monounsaturated fatty acids, oleic predominates. Indicators of polyunsaturated fatty acids of arachinic and arachidonic did not change, but the content of linoleic and linolenic fatty acids in the rams of the experimental groups decreased.

The comparative analysis of the ratio characterizing the biological effectiveness of fats indicates its improvement in animals consuming test supplements.

#### 4. CONCLUSIONS:

Thus, the chemical composition and physical properties of the internal raw fat tended to change in the intergroup aspect. At the same time, its energy saturation increased due to the accumulation of chemically pure fat, and the biological value decreased due to a decrease in the total amount of polyunsaturated fatty acids. However, the changes occurring in the adipose tissue of young sheep were within the

physiological norm and corresponded to breed characteristics. The data obtained indicate that only a differentiated approach to the quality of raw materials, taking into account a balanced feed background of sheep, makes it possible to choose the most optimal variant of its rational use.

### RESUMO

A infecção da toxoplasmose é causada por parasitas protozoários intracelulares chamados *Toxoplasma gondii*. O animal e o humano podem sofrer as infecções por diferentes vias. Algumas pessoas com status imunocomprometido estão em alto risco de infecção; exemplos desses grupos são gestantes, fetos e recém-nascidos. Este estudo teve como objetivo avaliar o papel da infecção por toxoplasma na manifestação de abortos e outros distúrbios congênitos entre mulheres casadas com idades entre 18 e 45 anos na cidade de Maysan (no sul do Iraque). Os critérios de inclusão incluem o grupo de estudo com histórico de infecção por *Toxoplasma gondii* (100 mulheres) e, para controles, aqueles que estavam livres de toxoplasmose (100 mulheres). Os critérios de exclusão foram gestantes, solteiras e portadoras de doenças imunossupressoras. As amostras de soro foram testadas quanto a IgG e IgM contra antígenos de *Toxoplasma gondii* usando o sistema de imunoenensaio automático Biomerieux Mini VIDAS, que dependia do princípio da tecnologia *Enzyme Linked Fluorescent Assay* (ELFA). O estudo revelou que as mulheres não abortadas infectadas eram 14 (14%), enquanto as mulheres não abortadas não infectadas eram 24 (24%). As mulheres infectadas com um caso de aborto foram sessenta (60,0%), enquanto as mulheres não infectadas com um caso de aborto foram 40 (40,0%). As mulheres infectadas que tiveram dois casos de aborto e aquelas infectadas que tiveram mais de dois casos de aborto foram 26 (26%) e 14 (14%), respectivamente. Houve diferença estatisticamente significativa entre mulheres infectadas e não infectadas em relação ao aborto ( $p < 0,01$ ). Verificou-se que houve diferenças altamente significativas entre mulheres infectadas e não infectadas em relação a anomalias e partos por cesariana (valor de  $p = 0,001$ ). Houve diferença estatisticamente significativa (valor de  $p = 0,01$ ) entre mulheres infectadas e não infectadas em relação ao parto com ou sem bebês prematuros.

**Palavras-chave:** *Toxoplasma gondii*, abortos, anomalias, cesarianas, bebês prematuros

### ABSTRACT

Toxoplasmosis is a disease caused by intracellular protozoan parasites called *Toxoplasma gondii*. The animal and human could suffer from infections through different routes involving diets, non-hygienic habit, contacts to soil, as well as blood transfusions and organs grafting. Some people with immune-compromised status are at a high risk of infection; examples of these groups are pregnant women, fetuses, and newborns. This study aimed to evaluate the role of Toxoplasma infection in the manifestation of abortions and other congenital disturbances among married women aged 18 to 45 years in Maysan city (in the south of Iraq). Inclusion criteria include the study group with a history of infection with *Toxoplasma gondii* (100 females) and for controls, those who were free from toxoplasmosis (100 females). Exclusion criteria were pregnant women, unmarried women, and those suffering from immunosuppressive diseases. The serum samples were tested for IgG and IgM against *Toxoplasma gondii* antigens by using the Biomerieux Mini VIDAS automated immunoassay system, which depended on the principle of Enzyme-Linked Fluorescent Assay (ELFA) technology. The study revealed that infected non-aborted women were 14 (14%), while non-infected non-aborted women were 24 (24%). Infected women with one case of abortion were sixty (60.0%), while non-infected women with one case of abortion were 40 (40.0%). The infected women who had two abortion cases and those infected ones who had more than two cases of abortions were 26 (26%) and 14 (14%), respectively. There was a statistically significant difference between infected and uninfected women regarding abortion ( $p < 0.01$ ). It has been found that there were highly significant differences between infected and non-infected women concerning anomalies and deliveries by cesarean sections ( $p$ -value = 0.001). There was a statically significant difference ( $p$ -value = 0.01) between infected and non-infected women concerning their deliveries with or without premature babies.

**Keywords:** *Toxoplasma gondii*, abortions, anomalies, cesarean sections, premature babies.

## المخلص:

داء المقوسات هو مرض تسببه طفيليات البروتوزا الداخلية الخلوية والتي تدعى المقوسات الكوندية. تصيب هذه الطفيليات كل من الانسان والحيوان من خلال العديد من الطرق وتشمل الغذاء ، العادات غير الصحية ، التماس مع التربة بالإضافة الى نقل الدم وزراعة الاعضاء . اكثر الاشخاص عرضة للإصابة هم الذين تكون مناعتهم ضعيفة ومن الأمثلة على ذلك النساء الحوامل ، الأجنة ، وكذلك حديثي الولادة. تهدف هذه الدراسة الى تقييم دور الإصابة بداء المقوسات في حصول الاجهاض وبقيّة الاضطرابات الخلقية لدى النساء المتزوجات للأعمار من 18 الى 45 في مدينة ميسان (في جنوب العراق). المعايير المتضمنة شملت مجموعة الدراسة والتي كانت مكونة من الاناث المصابات بالمقوسات الكوندية وعددهن 100 امرأة ، وشملت ايضاً مجموعة السيطرة والتي هي الاخرى مكونة من 100 امرأة ولكنهن غير مصابات بهذه الطفيليات. المعايير المستثناة من الدراسة هي النساء الحوامل ، غير المتزوجات ، وكذلك النساء الاتي يعانين من الأمراض المثبطة للمناعة. عينات مصل الدم فحصت للتحري عن وجود الاجسام المناعية المضادة للمقوسات الكوندية من نوع (IgM) و (IgG) وذلك باستخدام جهاز (Biomerieux Mini VIDAS) بنظام الطرق المناعية الآلية والتي تعتمد على تقنية الفحص المتألق المرتبط مناعياً (ELFA). اظهرت الدراسة ان النساء المصابات غير المجهاضات كانت اعدادهن 14 (14%) بينما غير المصابات من اللواتي لم يحدث عندهن اجهاض كانت اعدادهن 24 (24%). النساء المصابات مع حالة اجهاض واحدة كانت اعدادهن 60 (60%) بينما غير المصابات مع حالة اجهاض واحدة كانت اعدادهن 40 (40%). المصابات مع حالتها اجهاض والمصابات مع اكثر من حالتها اجهاض كانت اعدادهن 26 (26%) و 14 (14%) على التوالي ، مع فرق معنوي احصائي بين أعداد المصابات وغير المصابات حيث كانت p-value اصغر من 0.01 ( $p < 0.01$ ). كما قد وجد ان هناك فرق معنوي عالي بين أعداد النساء المصابات وغير المصابات فيما يخص التشوهات وحالات الوضع بواسطة العمليات القيصرية ( $p\text{-value} = 0.001$ ). كما ان هناك فرق معنوي احصائي ( $p\text{-value} = 0.01$ ) بين أعداد المصابات وغير المصابات فيما يتعلق بولادة النساء لحديثي الولادة غير المكتملين (الخدج)

**الكلمات المفتاحية:** مقوسة كوندية ، الاجهاضات ، التشوهات ، العمليات القيصرية ، أطفال الخدج

## 1. INTRODUCTION:

Toxoplasmosis is a disease caused by *Toxoplasma gondii* that can infect animal and human (Lu *et al.*, 2015; Robert-Gangneux and Darde, 2012).

*T. gondii* divided into three stages: tachyzoites, bradyzoites (tissue cysts), and sporozoites (in cats' feces). It can be transmitted by ingestion of contaminated fruit, vegetable, under-cooked meats, unpasteurized milk as well as low hygiene around food and cook-ware. Another route of transmission is through contact with contaminated soil or by changing the cat litter box (Kaakour *et al.*, 2019 ; Soares and Caldeira, 2019). Around 30% of the world's population is assumed to be infected with *T. gondii* (Montoya and Liesenfeld, 2004).

In immune-competent humans, the toxoplasmosis is commonly asymptomatic. Still, it can be fatal in immune-compromised persons, such as patients with HIV and cancer in addition to organ transplant recipients and pregnant women (Lu *et al.*, 2015; Agrawal *et al.*, 2014).

*T. gondii* causes encephalitis and neurologic defects, and it can affect the heart, inner ears, eyes (chorioretinitis), and liver. Although rare, congenital toxoplasmosis (infection of the infant) leads to ocular (retinochoroiditis) or severe permanent neurological disease, as well as brain and cardiac anomalies (Montoya, 2002). The clinical effects of toxoplasmosis among pregnant women are various. Such women may suffer from spontaneous abortions, stillbirth, intrauterine

growth retardation, deliveries of premature babies and anomalies in fetus. Furthermore, it has been suggested that *Toxoplasma* infections have some undesired implications on the capacity of the reproductive organ in both males and females (Flegr, 2013).

The infection of pregnant women with the *Toxoplasma* parasite is linked to exposure to cats and the age. This infection can lead to delivery with cesarean section and to *Toxoplasma* infected newborn (Kaakour *et al.*, 2019).

The study aimed to investigate the possible association between toxoplasmosis and some congenital disturbances among women who attended at Al. Sadr Teaching Hospital in Maysan city.

## 2. MATERIALS AND METHODS:

After finding the female eligible for the present study, she was explained the nature of the study and consent was sought. Those willing to give the consent and able to cooperate brief history were taken from them in the college of Nursing.

### 2.1. Study design

A case-control research was conducted in Al. Sadr Teaching Hospital, from July 2019 to February 2020. The study applied to married women aged 18 to 45 years with the exclusion of pregnant and unmarried women and those suffering from immunosuppressive diseases. A total number of 200 females were categorized into

two groups: Study group included 100 females who were infected with *Toxoplasma gondii*, another (control) group including 100 non-infected women, and without previous history of infection with toxoplasmosis.

## 2.2. Procedure

Five milliliters of antecubital venous blood was collected from each female in a sterile test tube and left for 30 minutes at room temperature until the clot has appeared in the blood. Then these blood samples were centrifuged to 4000 round/minute (for 10 minutes) to separate the serum. Sera were stored at -20°C till tested.

The serum samples were tested for IgG and IgM against *Toxoplasma gondii* antigens by using Biomerieux Mini VIDAS automated immunoassay system, which depended on the principle of Enzyme Linked Fluorescent Assay (ELFA) technology.

## 2.3. Statistical analysis

Statistical analysis was done using the statistical package for social sciences (SPSS version 18). Chi-square tests and descriptive statistics were applied to measure the frequencies and levels of significance—the values considered to be significant if P value < 0.05.

## 3. RESULTS AND DISCUSSION:

According to the findings in Table 1, it was revealed that the majority of infected women were located in the 21-25 years age group (38%). Almost more than half numbers of infected women were found in the first two groups compared to other groups. These results indicated that toxoplasmosis has occurred at an early age, more than the old ages of women in the current study. The findings have disagreed with many studies which found out that, the raised level of *Toxoplasma* infection was among 35-45 age groups, in comparison with a reduced rate of toxoplasmosis at 15-19 age groups (Al-Kalaby *et al.*, 2016; Sroka *et al.*, 2010; Jassam, 2010; AL-Ani, 2012; Al-Harthi *et al.*, 2006).

The indication of Table 1 was in agreement with findings of other studies, which demonstrated that the infection of *Toxoplasma* parasite was higher in the younger ages (Suhaila, 2008; Tasawar *et al.*, 2012). More upper infections that occur in young individuals may be due to the association with poor sanitary habits

and lower immunity against this *Toxoplasma gondii* (Jones *et al.*, 2008).

Table 2 revealed that infected non-aborted women were 14 (14%) while non-infected women who had not any abortion history were 24 (24%). Sixty (60.0%) positive women had a history of one case of abortion while 40 (40.0%) negative women had a previous one abortion. According to the table, the infected women with a history of two abortion cases were 26 (26%), while those non-infected women who had the same number of abortions were 18 (18%). In the case of more than two abortion histories, the number of infected women was 14 (14%), while negative women for toxoplasmosis were 4 (4%). The comparative evaluation of these results indicates that there was a significant difference ( $p < 0.01$ ) between non-infected and infected women with abortion.

The present study demonstrated that there was statically significant ( $p$ -value = 0.01) when applied cross-tabulation between infection and abortion (Table 2). Simultaneously, Table 3 showed that 35 (35.0%) of infected women had newborns with different anomalies compared to 14 (14.0%) of non-infected women ( $p$ -value = 0.001). These results were in line with several studies which indicated a correlation between infection with toxoplasmosis and congenital anomalies as well as previous history of abortion (Al-Kalaby *et al.*, 2016; Al-haris *et al.*, 2014; Muqbil *et al.*, 2014; Amin *et al.*, 2012; Mohamed *et al.*, 2012).

The findings of data analysis, as showed in Table 4 revealed that infected women with cesarean section deliveries were 17 (17.0%) in compared to 9 (9.9%) non-infected women who had deliveries by cesarean section. Contrarily, the infected women with standard deliveries were noticeably less than non-infected women 29, 49, respectively. Hence, the  $p$ -value was highly significant (0.005). These findings were approximately in agreement with the study that achieved in Lebanon (Kaakour *et al.*, 2019).

The correlation between toxoplasmosis premature babies was determined in Table 5 which revealed that there were 28 (28.0%) of infected women had premature babies while non-infected women were 11 (11.0%) only. The significant difference was high ( $p$ -value = 0.01). These findings were supported by another study, which indicated that the associations between prematurity and severity of congenital toxoplasmosis, including severe eye and brain disease (McLeod *et al.*, 2012).

#### 4. CONCLUSIONS:

According to the study, it has been found that the Infection of women with *T.gondii* is associated with abortions and different anomalies that occur in fetuses and newborns. This infection may lead to cesarean section deliveries and preterm births.

#### 5. ACKNOWLEDGMENTS:

We would like to thank each technician in the laboratory of Al-Sadr Teaching Hospital for their help to complete this study. A special thanks to Shaima R. Banoon and Hadi Hussein Mahdi for his valuable and constructive suggestions during the development of this research work.

### RESUMO

A equação de Schrödinger em uma coordenada toroidal foi proposta na física teórica para obter as informações e o comportamento do sistema de partículas. Foi resolvido recentemente, no caso de uma partícula escalar carregada interagindo com um campo magnético uniforme, um campo elétrico uniforme e uma carga neutra restringida à superfície. A metodologia usada no referido trabalho foi resolver a equação de Schrödinger usando uma abordagem descrita no tratado Whittaker-Watson que lida com um problema de valor próprio infinito-dimensional e com valores particulares específicos do campo aplicado para o problema de função própria, enquanto no problema da mecânica quântica um tinha um problema de autovalor generalizado de dimensão infinita. Este estudo teve como objetivo obter o valor próprio de energia não-relativística e a função de onda radial da equação de Schrödinger sob a influência do potencial de Yukawa. O método da Mecânica Quântica Supersimétrica (SUSY QM) foi usado como base para abordar o objetivo principal deste artigo, estudar o problema de uma partícula com massa variável em coordenadas toroidais. O super potencial adequado foi usado para lidar com a forma hiperbólica do potencial efetivo e os espectros de energia foram calculados para diferentes números quânticos, profundidade potencial e parâmetros potenciais. A equação da função de onda radial para o solo e o estado excitado foi obtida. Os resultados mostraram que o valor crescente dos números quânticos fez com que os espectros de energia do sistema aumentassem para o valor mais alto quando o número quântico era igual ao parâmetro potencial, o que significa que o valor energético mais eficaz foi produzido e depois diminuiu. Enquanto o valor da energia não dependia da alteração do parâmetro potencial. Essa propriedade poderia ser usada para produzir essa equação como uma aplicação dos resultados anteriores. A função própria de Schrödinger foi usada como ponto de partida para resolver a outra equação no mesmo cenário e potencial geométrico.

**Palavras-chave:** *Valor próprio da energia, espectros de energia, função de onda no estado fundamental*

### ABSTRACT

Schrodinger equation on a toroidal coordinate was proposed in theoretical physics to get the information and the behavior of the system of particle. It was solved just recently in case of a charged scalar particle interacting with a uniform magnetic field, a uniform electric field, and a neutral charge constrained to the surface. The methodology used in the referred work was to solve the Schrodinger equation using an approach outlined in the Whittaker-Watson treatise, which deals with an infinite-dimensional eigenvalue problem and specific particular values of the applied field for eigenfunction problem. In contrast, in the quantum mechanical problem, one had an infinite-dimensional generalized eigenvalue problem. This study aimed to obtain the non-relativistic energy eigenvalue and the radial wave function of the Schrodinger equation under the influence of Yukawa potential. The Supersymmetric Quantum Mechanics (SUSY QM) method was used as a basis to tackle the primary objective of this paper to study the problem of a particle with variable mass in toroidal coordinate. The proper super potential was used to deal with the hyperbolic form of effective potential, and the energy spectra were calculated for different quantum numbers, potential depth, and potential parameters. The radial wave function equation for ground and excited state were obtained. The results showed that the increasing value of the quantum numbers caused the energy spectra of the system to increase to the highest value when the quantum number was equal to the potential parameter, which means the most effective energy value was produced, then it was decreased

afterward. While the energy value did not depend on the change of the potential parameter. This property could be used to produce this equation as an application of the previous results, the Schrödinger eigenfunction was used as the starting points to solve the other equation in the same geometrical setting and potential.

**Keywords:** Energy eigenvalue, energy spectra, ground-state wave function

## 1. INTRODUCTION:

There had been increasing interest in theoretical physics to obtain the exact solution of the Schrodinger equation in spacetimes with non-spherical topology and negative cosmological constant (Krisch and Glass, 2003). The main purposes of this interest were to obtain the energy eigenvalue and the wave function. It was important to understand because it contained all the information about the quantum system. However, SUSY QM allowed one to determine eigenvalues and eigenstates of known analytically solvable potentials using algebra operator formalism without ever had to solve the Schrödinger differential equation by standard series method (Cari *et al.*, 2014). The other methods have been used to solve the Schrodinger equation, such as the Hypergeometric method (Dianawati *et al.*, 2018), Nikiforov-Uvarov method (Onate *et al.*, 2018), and Asymptotic Iteration Method (Elviyanti *et al.*, 2018).

The method of separation of variables in various coordinate systems was a classic approach to find the exact solutions of the Schrodinger equation that had been thoroughly studied. One such set of coordinates was the toroidal system, but it will be argued that some of the usefulness of this coordinate system had been hidden. It was because, while the usual way of separating the variables was appropriate for some situations, there was another way that more suited to a certain class of problems, in particular, some interesting problems in electrostatics (Andrews, 2006)

The toroidal coordinates (Moon and Spencer, 1971) of any point were given by the intersection of a torus, a sphere with its center on the axis of the torus (the z-axis), and an azimuthal half-plane (terminated by the z-axis). A toroid with a circular cross-section was a torus, so a torus was a toroid, and tori were toroids (Lucht, 2016). The radius and center of the sphere were determined by the spherical coordinate  $\mu$ , the major and minor radii of the torus were given by the toroidal coordinate  $\eta$ , and the particular half-plane was specified by its azimuthal angle  $\phi$ .

The solutions for the Schrodinger equation with a position-dependent mass lie at the center of

interest of the professional public because it helped us to understand the behavior of quantum particles in the cases in which their mass varies spatially (Bednarik and Cervenka, 2017). For instance, the variable mass Schrodinger equation played an essential role in the study of the electronic properties of inhomogeneous crystals, quantum dots, and quantum liquids (Golubov and Mazin, 1997). A suitable choice of a mass position function of the exponential-like form had been devised (Meyur, *et al.*, 2014). However, the application of variable mass in the Schrodinger equation was needed to be studied in a significant way.

Energy eigenvalue and wave function of non-relativistic particle have been solved using Schrodinger equation in the presence of many potentials such as Eckart potential (Goudarzi and Vahidi, 2011), Poschl-Teller (Suparmi *et al.*, 2012), Hylleraas (Suparmi *et al.*, 2017), and ring-shaped pseudo-harmonic oscillatory (Oliveira and Schmidh, 2019). The energy eigenvalue and wave function also could be used to determine other properties and further information of the system such as thermodynamics properties (Adebimpe *et al.*, 2019), entropy information (Faniandari *et al.*, 2019; Ma'arif *et al.*, 2019) and optical properties (Falkovsky, 2008).

The hyperbolic form of Yukawa potential was put into the formulation of the radial part of the Schrodinger equation in toroidal coordinates. The supersymmetric quantum mechanics method and variable mass were used. Therefore, this study aimed to obtain the energy eigenvalue, the un-normalized ground state wave function, and the exciting wave function of the system.

## 2. MATERIALS AND METHODS:

### 2.1. Schrödinger Equation with Variable Mass

The Laplacian in this coordinate was given by:

$$\nabla^2 \Psi = \frac{1}{h_\mu^3} \left[ \frac{1}{\sinh \mu} \frac{\partial}{\partial \mu} \left( h_\mu \sinh \mu \frac{\partial \Psi}{\partial \mu} \right) + \frac{\partial}{\partial \eta} \left( h_\eta \frac{\partial \Psi}{\partial \eta} \right) + \frac{h_\mu}{\sinh^2 \mu} \frac{\partial^2 \Psi}{\partial \phi^2} \right] \quad (\text{Eq. 1})$$

where

$$\Psi = \sqrt{\cosh \mu - \cos \eta} F(\mu, \eta, \phi) \quad (\text{Eq. 2})$$

$$h_\mu = h_\theta = \frac{a}{\cosh \mu - \cos \eta} \quad (\text{Eq. 3a})$$

$$h_\phi = \frac{a \sinh \mu}{\cosh \mu - \cos \eta} \quad (\text{Eq. 3b})$$

After applying the general wave function and scaling factors, the Laplacian could be simplified, so the Schrodinger equation with energy eigenvalue and potential was defined as

$$\left\{ \frac{(\cosh \mu - \cos \eta)^2}{a^2} \left[ \frac{1}{\sinh \mu} \frac{\partial}{\partial \mu} \left( \sinh \mu \frac{\partial F}{\partial \mu} \right) + \frac{\partial^2 F}{\partial \eta^2} \right] + \frac{1}{\sinh^2 \mu} \frac{\partial^2 F}{\partial \phi^2} + \frac{1}{4} F \right\} - \frac{2m}{\hbar^2} V F(\mu, \eta, \phi) = - \frac{2m}{\hbar^2} E F(\mu, \eta, \phi) \quad (\text{Eq. 4})$$

The variable mass was proposed as

$$m \approx \frac{m_0 (\cosh \mu - \cos \eta)^2}{a^2} \quad (\text{Eq. 5})$$

**Figure 1.** Plot for mass function  $m$  with the variation of  $\eta$ ,  $m_0 = 1$ ,  $a = 1$

**Figure 2.** Plot for mass function  $m$  with the variation of  $\mu$ ,  $m_0 = 1$ ,  $a = 1$

The non-central potential was applied to Eq. (4) which expressed by

$$V(\mu, \eta, \phi) = V(\mu) + V(\eta) + \frac{V(\phi)}{\sinh^2 \mu} \quad (\text{Eq. 6})$$

Generally, the Schrodinger equation could be solved by reducing the system of particles to the second-order differential equation. For the wave function

$$F = M(\mu) H(\eta) P(\phi) \quad (\text{Eq. 7})$$

The angular parts were

$$\frac{\partial^2 H}{\partial \eta^2} - \frac{2m_0}{\hbar^2} V(\eta) H = \lambda_1 H \quad (\text{Eq. 8})$$

$$\frac{\partial^2 P}{\partial \phi^2} - \frac{2m_0}{\hbar^2} V(\phi) P = \lambda_2 P \quad (\text{Eq. 9})$$

and the radial part was

$$\begin{aligned} & -\frac{1}{\sinh \mu} \frac{\partial}{\partial \mu} \left( \sinh \mu \frac{\partial M}{\partial \mu} \right) + \frac{2m_0}{\hbar^2} V(\mu) M \\ & - \lambda_1 M - \left( \frac{1}{4} + \frac{2m_0 E}{\hbar^2} \right) M = \frac{\lambda_2}{\sinh^2 \mu} M \end{aligned} \quad (\text{Eq. 10})$$

The solution was simplified to be

$$\left\{ -\frac{\hbar^2}{2m_0} \frac{\partial^2 K}{\partial \mu^2} + \frac{\hbar^2}{2m_0} \frac{-\lambda_2 - \frac{1}{4}}{\sinh^2 \mu} K \right\} \quad (\text{Eq. 11})$$

$$+V(\mu)K - \lambda_1 \frac{\hbar^2}{2m_0} K - EK = 0$$

where  $M = \frac{K}{\sqrt{\sinh \mu}}$ .

## 2.2. Supersymmetric Quantum Mechanics Method

Quantum mechanics, in its development, had brought the concept of symmetry as a foundation for thinking to simplify physical systems. The concept of symmetry mathematically means the invariant nature of a system when subject to a particular transformation. Closed algebra under the anti-commutation relationship was introduced in the supersymmetry system. The Supersymmetry system in quantum mechanics was defined as a system consisting of a supercharge operator  $Q_i$  which was commutative towards Hamiltonian Supersymmetry ( $H_{SS}$ ) (Witten, 1981).

$$[Q_i, H_{SS}] = 0 \text{ and } i = 1, 2, \dots, N \quad (\text{Eq. 12})$$

where  $N$  was the number of generators and meets the anti-commutation relationship below

$$\{Q_i, Q_j\} = \delta_{ij} H_{SS} \quad (\text{Eq. 13})$$

Hamiltonian Supersymmetry ( $H_{SS}$ ) was defined as the sum of squares of the supercharge operator ( $Q_i$ ):

$$H_{SS} = 2Q_1^2 = 2Q_2^2 \quad (\text{Eq. 14})$$

The simplest SUSY QM system, where  $N = 2$  with supercharge operators  $Q_1$  and  $Q_2$  could be associated with spin 1/2 particles moving in a straight line.  $Q_1$  and  $Q_2$  in this simple system were defined as follows:

$$Q_1 = \frac{1}{\sqrt{2}} \left( \sigma_1 \frac{p}{\sqrt{2m}} + \sigma_2 \phi(x) \right) \quad (\text{Eq. 15a})$$

$$Q_2 = \frac{1}{\sqrt{2}} \left( \sigma_2 \frac{p}{\sqrt{2m}} - \sigma_1 \phi(x) \right) \quad (\text{Eq. 15b})$$

where  $\sigma_1$  and  $\sigma_2$  were matrices from Pauli (Suparmi, 2011).

$H_{SS}$  was Hamiltonian supersymmetry,  $p = -i\hbar \frac{d^2}{dx^2}$  was linear momentum (bosonic

momentum),  $x$  was bosonic coordinate, and  $\phi(x)$  was bosonic superpotential. Hamiltonian Supersymmetry matrix could be shown as:

$$H_{SS} = \begin{pmatrix} H_+ & 0 \\ 0 & H_- \end{pmatrix} \quad (\text{Eq. 16})$$

where

$$H_- = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \phi^2(x) - \frac{\hbar}{\sqrt{2m}} \frac{d\phi(x)}{dx} \quad (\text{Eq. 17a})$$

$$H_+ = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \phi^2(x) + \frac{\hbar}{\sqrt{2m}} \frac{d\phi(x)}{dx} \quad (\text{Eq. 17b})$$

Eq. (12) caused the results in the generation of degenerated energy  $H_-$  and  $H_+$ , which were SUSY partners of the Fermionic Hamiltonian (descendant) and Bosonic (ascending), both of which were also written as  $H_{SS}$ . The standard Schrödinger equation was stated in the Hamiltonian SUSY as follows

$$H_- = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + V_-(x) \quad (\text{Eq. 18a})$$

$$H_+ = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + V_+(x) \quad (\text{Eq. 18b})$$

where  $V_-(x)$  and  $V_+(x)$  were called as supersymmetry potential couple,  $\phi(x)$  was superpotential, while  $\phi'(x)$  was the first derivative of  $\phi(x)$ .

Lowering and raising Hamiltonian could be factorized from the equation (18a) and (18b) and respectively were stated as follows:

$$A^+ = -\frac{\hbar}{\sqrt{2m}} \frac{d}{dx} + \phi(x) \quad (\text{Eq. 19a})$$

$$A = \frac{\hbar}{\sqrt{2m}} \frac{d}{dx} + \phi(x) \quad (\text{Eq. 19b})$$

$A^+$  was raising operator and  $A$  was lowering operator (Rodrigues, 2002).

Based on the character of lowering operator ( $A$ ), if ( $A$ ) was operated on the ground state wave function  $\psi_0^{(-)}$ , it will equal to zero (Cooper *et al.*, 1995).

$$A\psi_0^{(-)} = \left( \frac{\hbar}{\sqrt{2m}} \frac{d}{dx} + \phi(x) \right) \psi_0^{(-)} = 0 \quad (\text{Eq. 20})$$

From Eq. (20), then the ground state wave function was determined as

$$\psi_0^{(-)}(x) = N \exp \left[ -\frac{\sqrt{2m}}{\hbar} \int_{-x}^x \phi(x) dx \right] \quad (\text{Eq. 21})$$

with  $N$  was the normalization factor.

### 3. RESULTS AND DISCUSSION:

The radial part of the Schrodinger equation with energy eigenvalue and potential was expressed as

$$-\frac{\hbar^2}{2m_0} \frac{\partial^2 K}{\partial \mu^2} + \frac{\hbar^2}{2m_0} \left[ -\frac{1}{4 \sinh^2 \mu} - \frac{\lambda_2}{\sinh^2 \mu} \right] K + V(\mu)K = \varepsilon' K \quad (\text{Eq. 22})$$

$$\text{with } \varepsilon' = \lambda_1 \frac{\hbar^2}{2m_0} + E.$$

Yukawa potential was used and it's general form was (Yukawa, 1935).

$$V(\rho) = -V_0 \frac{\hbar^2}{2m_0} \left( \frac{e^{-\xi \rho}}{\rho} \right) \quad (\text{Eq. 23})$$

By set  $\xi \rho = \mu$

$$V(\mu) = -V_0 \xi \frac{\hbar^2}{2m_0} \left( \frac{e^{-\mu}}{\mu} \right) \quad (\text{Eq. 24})$$

The following approximation for centrifugal terms was applied (Greene and Aldrich, 1976; Qiang and Dong, 2007; Jia, *et al.*, 2009; Dong, *et al.*, 2013).

$$\frac{1}{\mu^2} \approx 4\xi^2 \frac{e^{-2\xi\mu}}{(1 - e^{-2\xi\mu})^2} \quad (\text{Eq. 25})$$

$$\frac{1}{\mu} \approx \frac{2\xi e^{\mu}}{e^{2\mu} - 1} \quad (\text{Eq. 26})$$

Then Eq. (24) was modified as

$$V(\mu) = -\frac{\hbar^2}{2m_0} V_0 \xi^2 (\coth \mu - 1) \quad (\text{Eq. 27})$$

Eq. (27) was inserted into Eq. (22)

$$-\frac{\hbar^2}{2m_0} \frac{\partial^2 K}{\partial \mu^2} + \frac{\hbar^2}{2m_0} \left[ \frac{v(v-1)}{\sinh^2 \mu} - V_0 \xi^2 \coth \mu + V_0 \xi^2 \right] K = \left( \lambda_1 \frac{\hbar^2}{2m_0} + E \right) K \quad (\text{Eq. 28})$$

$$\text{where } -\frac{1}{4} - \lambda_2 = v(v-1).$$

This was the second-order differential equation of the Schrodinger equation. The shape invariant potential was used, so the hypothetical superpotential function in supersymmetric quantum mechanics was

$$\Phi(\mu) = A \coth \mu + B \quad (\text{Eq. 29})$$

to satisfy the Riccati equation below

$$\Phi^2(\mu) - \frac{\hbar}{\sqrt{2m_0}} \Phi'(\mu) = V_{\text{eff}} - \varepsilon \quad (\text{Eq. 30})$$

$$\left( A^2 + \frac{\hbar}{\sqrt{2m_0}} A \right) \text{csch}^2 \mu + 2AB \coth \mu + A^2 + B^2 = \frac{\hbar^2}{2m_0} (v(v-1) \text{csch}^2 \mu - V_0 \xi^2 \coth \mu + V_0 \xi^2) - \varepsilon \quad (\text{Eq. 31})$$

where  $\varepsilon$  was the lowest energy eigenvalue. Comparing the left and the right side of Eq. (31), the solutions were determined.

$$A = \frac{\hbar}{\sqrt{2m_0}} v \quad (\text{Eq. 32})$$

$$B = -\frac{\hbar}{\sqrt{2m_0}} \frac{V_0 \xi^2}{2v} \quad (\text{Eq. 33})$$

$$\varepsilon = \frac{\hbar^2}{2m_0} \left( V_0 \xi^2 - \frac{(V_0 \xi^2)^2}{4v^2} - v^2 \right) \quad (\text{Eq. 34})$$

With Eq. (29), Eq. (32), Eq. (33), Eq. (18a) and Eq. (18b), the two partner potentials which have an invariant form were constructed as follows:

$$V_-(a_0, \mu) = \frac{\hbar^2}{2m_0} \left( \frac{(v^2 + v) \text{csch}^2 \mu - V_0 \xi^2 \coth \mu}{+\frac{(V_0 \xi^2)^2}{4v^2} + v^2} \right) \quad (\text{Eq. 35})$$

$$V_+(a_0, \mu) = \frac{\hbar^2}{2m_0} \left( \frac{(v^2 - v) \text{csch}^2 \mu - V_0 \xi^2 \coth \mu}{+\frac{(V_0 \xi^2)^2}{4v^2} + v^2} \right) \quad (\text{Eq. 36})$$

Then, a new set of the parameter was defined as  $a_1 = v - 1$  from the old set of parameter  $a_0 = v$ .

$$V_-(a_1, \mu) = \frac{\hbar^2}{2m_0} \left( \frac{(v^2 - v) \operatorname{csch}^2 \mu - V_0 \xi^2 \coth \mu}{+ \frac{(V_0 \xi^2)^2}{4(v-1)^2} + (v-1)^2} \right) \quad (\text{Eq. 37})$$

$$V_+(a_1, \mu) = \frac{\hbar^2}{2m_0} \left( \frac{((v-1)^2 - (v-1)) \operatorname{csch}^2 \mu}{-V_0 \xi^2 \coth \mu + \frac{(V_0 \xi^2)^2}{4(v-1)^2} + (v-1)^2} \right) \quad (\text{Eq. 38})$$

In term of the parameter of the problem, the following relations were obtained:

$$R(a_1) = V_+(a_0, \mu) - V_-(a_1, \mu) = \frac{\hbar^2}{2m_0} \left( \frac{(V_0 \xi^2)^2}{4v^2} - \frac{(V_0 \xi^2)^2}{4(v-1)^2} + v^2 - (v-1)^2 \right) \quad (\text{Eq. 39})$$

$$R(a_2) = V_+(a_1, \mu) - V_-(a_2, \mu) = \frac{\hbar^2}{2m_0} \left( \frac{(V_0 \xi^2)^2}{4(v-1)^2} - \frac{(V_0 \xi^2)^2}{4(v-2)^2} + (v-1)^2 - (v-2)^2 \right) \quad (\text{Eq. 40})$$

The energy eigenvalue was determined as:

$$E_n^{(-)} = \sum_{k=1}^n R(a_k) = \frac{\hbar^2}{2m_0} \left( \frac{(V_0 \xi^2)^2}{4v^2} - \frac{(V_0 \xi^2)^2}{4(v-n)^2} + v^2 - (v-n)^2 \right) \quad (\text{Eq. 41})$$

This gave the energy equation as

$$E_n = E_n^{(-)} + E_0 = \frac{\hbar^2}{2m_0} \left( V_0 \xi^2 - \left( \frac{V_0 \xi^2}{2(v-n)} \right)^2 - (v-n)^2 \right) \quad (\text{Eq. 42})$$

where  $\hbar$  was Planck constant,  $m_0$  was the mass of the particle,  $V_0$  was the potential depth,  $\xi$  was the potential width,  $v$  was the parameter of Yukawa potential, and  $n$  was the quantum number.

From Eq. (42), the energy spectra were determined from the energy eigenvalue with the variation of the quantum number, potential depth, and parameter of Yukawa potential in Table 1.

In Figure 3, when  $v=1$  and  $v=2$  the graph was tended to tilt to the left, while  $v=4$  and  $v=5$  the graph was tended to tilt to the right. It was

symmetrical at the center when  $v=n=3$ . Table 1 and Figure 3 showed that the increasing value of the quantum number ( $n$ ) causing the energy value to increase until it reached the highest value when  $n = v$ . After that, the energy value was decreased for the system in a toroidal coordinate. It also had a symmetric curve and when  $n = v$  it became the axis of symmetry.

**Figure 3.** Energy spectra of Yukawa potential in toroidal coordinate ( $V_0 = 0$ ,  $\hbar = 1$ ,  $m_0 = 1$ ,  $\xi = 0,01$ )

For the increasing value of the potential parameter  $v$ , the energy both increased and decreased. So, practically the potential parameter did not have a direct impact on the value of the energy.

To obtain the un-normalized wave function, the superpotential was defined again as stated in Eq. (29).

$$\Phi(\mu) = \frac{\hbar}{\sqrt{2m_0}} \left( v \coth \mu - \frac{V_0 \xi^2}{2v} \right) \quad (\text{Eq. 43})$$

The relation of shape invariance in SUSY QM was used and the raising and lowering operators were obtained from Eq. (43).

$$A^\dagger = -\frac{\hbar}{\sqrt{2m_0}} \frac{d}{d\mu} + \frac{\hbar}{\sqrt{2m_0}} \left( v \coth \mu - \frac{V_0 \xi^2}{2v} \right) \quad (\text{Eq. 44})$$

$$A = \frac{\hbar}{\sqrt{2m_0}} \frac{d}{d\mu} + \frac{\hbar}{\sqrt{2m_0}} \left( v \coth \mu - \frac{V_0 \xi^2}{2v} \right) \quad (\text{Eq. 45})$$

So, the ground state wave function  $\Psi_0^{(-)}$  was obtained

$$\left\{ \frac{\hbar}{\sqrt{2m_0}} \frac{d}{d\mu} + \Phi(\mu) \right\} \Psi_0^{(-)} = 0 \quad (\text{Eq. 46})$$

$$\Psi_0^{(-)} = \frac{CV_0 \xi^2 \mu}{2\nu} \sinh^{-\nu} \mu \quad (\text{Eq. 47})$$

The raising operator in Eq. (44) was operated to the ground state wave function  $\Psi_0^{(-)}$  in Eq. (47) and the un-normalized excited wave function was determined.

$$\Psi_1^{(-)}(x; a_0) = \Psi_0^{(-)} \frac{\hbar}{\sqrt{2m_0}} \frac{\nu}{\nu+1} \left( \frac{\sinh \mu}{v \coth \mu - \frac{V_0 \xi^2}{2\nu} - \frac{1}{\mu}} + (v+1) \cosh \mu \right) \quad (\text{Eq. 48})$$

#### 4. CONCLUSIONS:

The analytical solution of the Schrodinger equation using Yukawa potential in the form of hyperbolic function in the toroidal coordinate was obtained. The energy spectra and wave function were solved with the Supersymmetric Quantum Mechanics method (SUSY QM). The energy spectra were reported numerically based on the energy eigenvalue equation. The un-normalized ground state wave function and the excited state wave function was determined by operating the lowering and raising operator.

### RESUMO

Os cristais líquidos são únicos em suas propriedades e usos e têm um papel essencial na área de aplicações tecnológicas como elétrica, ótica, *display*, mapa de temperatura e materiais de comutação. Este estudo teve como objetivo sintetizar derivados de hexaetnilbenzeno a partir de 1,3,5-triclorobenzeno benzeno como núcleo central substituído por três anéis aromáticos e três braços de 2-cloro-4,6-bis ((3,7-dimetiloct-6-en-1-il) oxi) -1,3,5-triazina. Essas moléculas são formadas pela ligação covalente de três braços simetricamente a um núcleo central que podem ser ligados ao núcleo central através de ligantes flexíveis, semiflexíveis ou rígidos. A substituição ocorre na periferia acetilênica no anel central do benzeno e foi obtida com eficiência pelo acoplamento Sonogashira. Os compostos de seis braços baseados no núcleo do benzeno foram misturados com a razão complementar 1:1 do ácido 4-dodeciloxibenzóico, que já possuía propriedades de cristais líquidos para aumentar a possibilidade de formação destes resultando em um sal orgânico. Os sais orgânicos obtidos foram investigados quanto ao seu comportamento em cristal líquido por microscopia óptica de polarização (POM) e calorimetria de varredura diferencial (DSC). Todos os compostos intermediários e finais foram confirmados por técnicas espectroscópicas (1H RMN, 13C RMN e espectrometria de massa).

### ABSTRACT

Liquid crystals are unique in their properties and use and has an essential role in the area of technological applications such as electrical, optical, displays, temperature maps, and switching materials. This study aimed to synthesize hexaethynylbenzene derivatives starting from 1,3,5-trichlorobenzene benzene as a central core substituted with three aromatic ring and three armed of 2-chloro-4,6-bis((3,7-dimethyloct-6-en-1-yl) oxy)-1,3,5-triazine. These molecules are formed by the covalent linking of three arms symmetrically to a central core which may be attached to the central core through flexible, semi-flexible or rigid linkers. The substitution occurred at the acetylenic periphery on the central benzene ring and was achieved efficiently by Sonogashira coupling. The six-armed compounds based on the benzene core was mixed with the complementary 4-dodecyloxybenzoic acid 1:1 ratio, which already possessed liquid crystal property to increase the formation of these resulting in an organic salt. The obtained organic salts were investigated for their liquid crystal behaviour by polarizing optical microscopy (POM) and differential scanning calorimetry (DSC). All the intermediate and final compounds were confirmed by spectroscopic techniques (1H NMR, 13C NMR, and mass spectrometry).

### 1. INTRODUCTION:

Liquid crystal displays (LCDs) are omnipresent in the modern world, representing probably the most prevalent, developed, and profitable technology of thermotropic liquid crystals (Bremer, 2013; Kato, 2018). This application is based on their sensitivity to external electric and magnetic fields, when molecules align fast and at low voltages. This property was the basis for their use in other exciting applications,

especially as sensors. Because of their fluid nature at a specific temperature, liquid crystals (LCs) are very easy to process in thin films, along with maintaining optical properties characteristic to crystalline materials, as the ability to rotate the polarized light plane (birefringence) (Scutaru, 2018).

The chemistry of triazine has gained much increased in the last few decades, due to their applications in organic synthesis and liquid crystal properties (Akkurt *et al.*, 2019). Hexa-

ethynylbenzene derivatives are interested molecular as liquid crystals (Praefcke, 1991; Al-Jumaili, 2020), nonlinear optical material (Kondo, 1995), core structures for dendritic (Kayser, 1999), light-harvesting materials (Mongin, 2000), and building blocks for two-dimensional carbon networks (Kehoe, 2000; Wan, 2000).

Substituted hexa-ethynylbenzenes, in which the ethynyl ends possess different functional groups, are attractive because it would be possible to change the above properties by modifying the substitution pattern of the terminal groups (Sonoda, 2001). The more frequently utilized nucleophilic substitution reactions have been mostly limited to amines and alcohols so far, providing selective substitution at the price of decreased cycloaddition ability due to the electron-donating nature of the new substituent (Boger, 1998; Sakya, 1997; Novák, 2003).

Organic  $\pi$ -conjugated systems, small molecules (Chow, 2014) and polymers, (Tan, 2020) are of great interest for sensing, optical and electronic applications (Usta, 2014). The group of discotic liquid crystals (DLC) offers the additional feature of self-organization, often as a columnar arrangement resulting in anisotropic properties, e.g. one-dimensional charge transport in the liquid-crystalline phase (Kaller, 2012).

Typical DLCs consist of electron-rich polycyclic aromatic units, e.g., triphenylene or hexabenzocoronene, (Kumar, 2005), whereas DLCs with an electron-deficient core are rather scarce (Kestemont, 2001).  $\pi$ -conjugated N-heterocyclic molecules with peripheral aliphatic chains can easily be functionalized to present highly ordered columnar mesomorphism, which results in exciting properties like one-dimensional (1D) high charge carrier mobilities regarding scientific and technological aspects (Gsänger, 2010; Sergeyev, 2007; Demus, 2011).

In the present study on the construction of extended  $\pi$ -electronic systems, it was performed the design and synthesis of new hexaethynylbenzene derivatives starting from 1,3,5-trichlorobenzene benzene as a central core substituted with three aromatic ring and three armed of 2-chloro-4,6-bis((3,7-dimethyloct-6-en-1-yl) oxy)-1,3,5-triazine. These molecules are formed by the covalent linking of three arms symmetrically to a central core (scheme 1). These arms may be linked to the central core through flexible or semi-flexible or rigid linkers. When the central core connecting to the linkers and three rigid arms, shape persistent star-shaped mesogens are obtained (Lehmann, M. 2009).

These molecules lack the shape anisotropy of discotic required to exhibit mesophases. Still, their ability to form mesophases is supported by the nanophase segregation of chemically or physically different molecular subunits and their tendency to fill the space efficiently in bulk (Pradhan, 2016). The advantage of six-armed design with concerning to discotic is the synthetic flexibility of the liquid crystal behaviour (Bisoyi, 2010).

Therefore, this study aimed to synthesize hexaethynylbenzene derivatives starting from 1,3,5-trichlorobenzene benzene as a central core substituted with three aromatic ring and three armed of 2-chloro-4,6-bis((3,7-dimethyloct-6-en-1-yl) oxy)-1,3,5-triazine.

**Scheme 1.** Synthesis route of six arms compounds.

## 2. MATERIALS AND METHODS:

### 2.1. Chemical and Reagents

Cyanuric chloride, dodecan-1-ol, ethynylbenzene, 1,3,5-trichlorobenzene, 2-iodothiophene, 2-ethynylpyridine, ethynyltrimethylsilane, copper iodide, potassium carbonate, tetrakis(triphenylphosphine)palladium and triethylamine. The solvents were used dry (THF, Dioxane) were obtained from distilling over phosphorous pentoxide (merck).

### 2.2. Measurement

Purity of the compounds was checked by TLC on silica gel 60 F<sub>254</sub> (Merck). Synthesized compounds are characterized by <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra using CDCl<sub>3</sub> as a solvent with TMS as an internal standard. IR spectra were recorded in KBr on a Shimadzu FTIR 8400S spectrophotometer. Mass spectra were recorded on a GCMS-QP 1000 mass spectrometer.

### 2.3. 2-chloro-4,6-bis((3,7-dimethyloct-6-en-1-yl)oxy)-1,3,5-triazine (2)

2,4,6-trichloro-1,3,5-triazine (**1**) (0.29g, 1.6 mmol), 3,7-dimethyloct-6-en-1-ol (0.5 g, 3.2 mmol) and  $K_2CO_3$  (0.45 g, 3.2 mmol) were dissolved in 10 mL of THF under argon atmosphere and stirred at 50°C overnight (Scheme 2). The solution was poured into a mixture of ethyl acetate (10 mL) and water (10 mL). The organic layer after separation dried with sodium sulfate. Under vacuum, the solvent was evaporated and the crude product purified by column chromatography with hexane/ethyl acetate (2.5% EtOAc) as an eluent to give white powder with yield (0.25 g, 41%).  $^1H$  NMR (500 MHz,  $CDCl_3$ ) (5.14 (dd,  $J=7.1, 1.3$  Hz, 2H), 4.5 (m, 4H,  $OCH_2$ ), 2.09 (m, 4H,  $CH_2$ ), 1.9 (m, 6H,  $CH_3$ ), 1.8 (m, 6H,  $CH_2$ ), 1.6-1.3 (m, 10H,  $CH_2$ ), 1.07-0.95 (m, 6H,  $CH_3$ ),  $^{13}C$  NMR (126 MHz,  $CDCl_3$ ) (172, 171, 131.5, 124, 69, 36.8, 35, 29, 25.7, 25.3, 19.2, 17.6). HRMS=  $M^{+}_{calcd}$  for  $C_{23}H_{38}ClN_3O_2$  = 424.27.  $(M+H)^{+}_{found}$  = 424.27 and  $(M+NH_4)^{+}_{found}$  = 441.311 (441.311 - 18 = 423.3).

### 2.4. 2,4-bis((3,7-dimethyloct-6-en-1-yl)oxy)-6((trimethylsilyl)ethynyl)-1,3,5-triazine (3)

2-chloro-4,6-bis((3,7-dimethyloct-6-en-1-yl)oxy)-1,3,5-triazine (**2**) (1.2 g, 2.5 mmol), ethynyltrimethylsilane (0.29 g, 2.96 mmol),  $K_2CO_3$  (0.4 g, 2.96 mmol),  $Pd(PPh_3)_4$  (0.28 g, 0.24 mmol) and CuI (0.09 g, 0.49 mmol), were dissolved in 10 mL of THF under argon atmosphere then refluxed for 6 hr. (Scheme 2). The solution was poured into a mixture of ethyl acetate (20 mL) and water (20 mL). The organic layer after separation dried with sodium sulfate. The solvent was removed under vacuum to give brown oily material with yield (1.1 g, 81%). HRMS=  $M^{+}_{calcd}$  for  $C_{28}H_{47}N_3O_2Si$  = 485.34.  $(M+H)^{+}_{found}$  = 486.33 and  $(M+Na)^{+}_{found}$  = 508.32 (508.32 - 23 = 485.32).

### 2.5. 1,3,5-trichloro-2,4,6-triiodobenzene (5).

Periodic acid (1.5 g, 6.55 mmol) was added slowly to 25 mL of concentrated sulfuric acid and stirred for one hour then Potassium iodide (3.25 g, 20 mmol) was added to the mixture slowly at 0°C, after the reaction reached room temperature, 1,3,5-trichlorobenzene (**7**) (0.39 g, 2.2 mmol) was added (Scheme 3). The solution was poured into a mixture of ethyl acetate (25 mL) and water (25 mL). The organic layer after separation dried with sodium sulfate. The solvent was removed under vacuum to give solid materials with a yield (0.75 g, 62%), MP. 280°C. HRMS=  $M^{+}_{calcd}$  for  $C_3Cl_3I_3$  = 557.62.  $(M+H)^{+}_{found}$  = 558.6 and  $(M+Na)^{+2}_{found}$  = 582.6.

### 2.6. ((2,4,6-trichlorobenzene-1,3,5-triyl) tris(ethyne-2,1-diyl)) tribenzene (6a)

1,3,5-trichloro-2,4,6-triiodobenzene (**5**) (0.5 g, 0.89 mmol), ethynylbenzene (0.27 g, 2.68 mmol),  $Pd(PPh_3)_4$  (0.01 g, 0.09 mmol), CuI (0.03 g, 0.18 mmol) and  $Et_3N$  (0.28 g, 2.86 mmol) were dissolved in 10 mL of dioxane under argon atmosphere then stirred at 75 °C for 6 hr. (Scheme 3). The solution was poured into a mixture of ethyl acetate (10 mL) and water (10 mL). The organic layer after separation dried with sodium sulfate. Under vacuum the solvent was evaporated and the crude product purified by column chromatography with hexane/ethyl acetate (5% EtOAc) as an eluent to give white powder with yield (0.35 g, 81%), MP. 140-145 °C.  $^1H$  NMR (500 MHz,  $CDCl_3$ ) (7.6 (m, 6H, Ar-H), 7.4 (m, 9H, Ar-H).  $^{13}C$  NMR (126 MHz,  $CDCl_3$ ) (142, 132.5, 129.2, 128.5, 121.8, 81.6, 74). HRMS=  $M^{+}_{calcd}$  for  $C_{30}H_{15}Cl_3$  = 481.80.  $(M+H)^{+}_{found}$  = 483.02, and  $(M+Na)^{+}_{found}$  = 505.0219.

### 2.7. 2,2',2''-((2,4,6-trichlorobenzene-1,3,5-triyl) tris(ethyne-2,1-diyl)) tripyridine (6b)

1,3,5-trichloro-2,4,6-triiodobenzene (**5**) (0.43 g, 0.76 mmol), 2-ethynylpyridine (0.24 g, 2.29 mmol),  $Pd(PPh_3)_4$  (0.09 g, 0.07 mmol), CuI (0.03 g, 0.15 mmol),  $Et_3N$  (0.24 g, 2.44 mmol) were dissolved in 10 mL of dioxane under argon atmosphere then stirred at 75°C for 6 hr. (Scheme 3). The solution was poured into a mixture of ethyl acetate (10 mL) and water (10 mL). The organic layer after separation dried with sodium sulfate. Under vacuum, the solvent was evaporated and the crude product purified by column chromatography with hexane/ethyl acetate (3% EtOAc) as an eluent to give white powder with yield (0.29 g, 78%), MP. 195-200 °C.  $^1H$  NMR (500 MHz,  $CDCl_3$ ) (7.45 (m, 3H), 7.42 (m, 6H), 7.3 (m, 3H).  $^{13}C$  NMR (500 MHz,  $CDCl_3$ ) (145.6, 140.8, 134, 133.8, 129.6, 128.69, 128.6, 100.4, 97.9). HRMS=  $M^{+}_{calcd}$  for  $C_{27}H_{12}Cl_3N_3$  = 483.02.  $(2M^{+})_{found}$  = 968.0178.

### 2.8. 6,6',6''-((2,4,6-tris(phenylethynyl)benzene-1,3,5-triyl) tris(ethyne-2,1-diyl)) tris(2,4-bis((3,7-dimethyloct-6-en-1-yl)oxy)-1,3,5-triazine) (7a).

((2,4,6-trichlorobenzene-1,3,5-triyl)tris(ethyne 2,1-diyl))tribenzene (**6a**) (0.15 g, 0.31 mmol), 2,4-bis((3,7-dimethyloct-6-en-1-yl)oxy)-6((trimethylsilyl)ethynyl)-1,3,5-triazine (**3**) (0.48 g, 0.99 mmol),  $Pd(PPh_3)_4$  (0.03 g, 0.03 mmol), CuI (0.01 g, 0.06 mmol) and  $K_2CO_3$  (0.15 g, 1.08 mmol), were dissolved in 10 mL of dioxane under argon atmosphere then stirred at

80 °C for 16 hours (Scheme 3). The solution was poured into a mixture of ethyl acetate (10 mL) and water (10 mL). The organic layer after separation dried with sodium sulfate. Under vacuum the solvent was evaporated and the crude product purified by column chromatography with hexane/ethyl acetate (2.5% EtOAc) as an eluent to give oily light brown material with yield (0.37 g, 74%). <sup>1</sup>H NMR (7.36 (m, 9H, Ar-H), 7.2 (m, 6H, Ar-H), 4.8 (s, 6H), 4.2 (t, 12H, OCH<sub>2</sub>), 1.9 (m, 12H, CH<sub>2</sub>), 1.74 (m, 18H, CH<sub>3</sub>), 1.5-1.3 (m, 12H, CH<sub>2</sub>), 1.1-0.88 (m, 36H, CH<sub>2</sub>), 0.7 (m, 18H, CH<sub>3</sub>). <sup>13</sup>C NMR (126 MHz, CDCl<sub>3</sub>) (172.5, 170.9, 133, 131.8, 129.7, 128.9, 125.1, 125.08, 122.3, 88.5, 86.45, 82, 74.4, 66.8, 42.8, 42.5, 37.7, 37.5, 36.4, 36.3, 30.22, 29.9, 29.4, 26.2, 25.9, 20.02, 19.9, 18.3, 13.7, 13.5, 13.25, 13.23). ## 2.10. 4-(dodecyloxy) benzoic acid (4-DBA) (8)

4-hydroxy benzoic acid (8.2 mmol), 1-bromododecane (5.5 ml, 23 mmol, 2.8 eq) and KOH (1.3 g, 23 mmol, 2.8 eq) were dissolve in (25 ml) of ethanol and reflux for two days (Scheme 4). The mixture was hydrolysis by adding 10% aqueous KOH (12 ml) and refluxed overnight. After cooling down, the reaction mixture was acidified with HCl (6 M), the precipitate filtered, washed with water and recrystallized from ethanol to obtain the pure product 4-dodecyloxybenzoic acid white solid material with yield (4.55 g, 91 %). <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>) (δ 8.10 (d, 2H), 6.98 (d, 2H), 4.07 (t, 2H), 1.84 (m, 2H), 1.48 (m, 2H), 1.37-1.28 (m, 16H), 0.91 (t, 3H). FT-IR (2914, 2848, 2559, 1670, 1604) cm<sup>-1</sup>.

## 2.11. Synthesis of Organic Salts 9(a,b)

4-DBA mesogenic unit (**8**) reacted with **7(a-b)** in 10 mL of dry THF with one to one ratio (Scheme 4). The resulting solution was sonicated for 15 min until observing a transparent solution. Then, the solvent was removed in vacuum.

**The organic salt (9a).** <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>) (7.92 (d, 2H), 7.4 (d, 6H, Ar-H), 7.24 (m, 9H, Ar-H), 6.8 (d, 2H, Ar-H), 4.97 (s, 6H), 4.2 (t, 12H, OCH<sub>2</sub>), 3.8 (t, 2H, OCH<sub>2</sub>), 1.78 (t, 18H, CH<sub>3</sub>), 1.6-1.3 (m, 24H, CH<sub>2</sub>), 1.1- 0.9 (m, 60H, CH<sub>2</sub>), 0.78 (m, 18H, CH<sub>3</sub>). <sup>13</sup>C NMR (171.7, 170, 165, 163, 132.5, 132.3, 131.3, 131.2, 129, 128, 124, 121.7, 121.3, 114.18, 81.5, 73.8, 68, 66, 42, 41.2, 37.3, 35.6, 32.4, 30.2, 31, 29.9, 29.8, 29.5, 28.8, 26.3, 25.8, 23.3, 22, 19.8, 18.1, 17, 14.6, 12). FT-IR (2916, 2846, 1674, 1603, 1522, 1503, 1459, 1425, 1362, 1335). HRMS= M<sup>+</sup><sub>calcd</sub> for C<sub>124</sub>H<sub>159</sub>N<sub>9</sub>O<sub>9</sub> = 1918.23. (M + 3K)<sup>+</sup><sub>found</sub> = 678.7.

**The organic salt (9b).** <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>) (7.9 (d, 2H, Ar-H), 7.58 (m, 6H), 7.4 (m, 3H), 7.22 (m, 3H), 6.75 (d, 2H, Ar-H), 4.9 (s, 6H), 4.2 (t, 12H, OCH<sub>2</sub>), 3.75 (t, 2H, OCH<sub>2</sub>), 1.78 (t, 18H, CH<sub>3</sub>), 1.6-1.3 (m, 24H, CH<sub>2</sub>), 1.1- 0.9 (m, 60H, CH<sub>2</sub>), 0.78 (m, 18H, CH<sub>3</sub>). FT-IR (2923, 2852, 1736, 1567, 1521, 1501, 1458, 1413). HRMS = M<sup>+</sup><sub>calcd</sub> for C<sub>121</sub>H<sub>156</sub>N<sub>12</sub>O<sub>9</sub> = 1921.21. (M+3K)<sup>+</sup><sub>found</sub> = 680.36 and 679.7.

## 3. RESULTS AND DISCUSSION:

In this study, six-armed compounds based on benzene ring as a central core was synthesized via sonogashira reaction. 1,3,5-trichlorobenzene and 2,4,6-trichloro-1,3,5-triazine were the starting material. The intermediate compound 2-chloro-4,6-bis((3,7-dimethyloct-6-en-1-yl) oxy)-1,3,5-

triazine was obtained by sequential nucleophilic substitution of chlorine atoms in cyanuric chloride and used further in the synthesis of six armed structures as described in (Scheme 2 - 4). The obtained compounds were confirmed by spectroscopic analysis and the organic salts were investigated by polarized optical microscope (POM) and differential scanning calorimetry (DSC).

The formation of ionic interaction between the six-armed  $\pi$ -conjugated system and the mesogenic carboxyl group was mainly studied by FT-IR. The carboxylic peak corresponding to 4-DBA at  $1670\text{ cm}^{-1}$  shifted to  $1566\text{ cm}^{-1}$  in both organic salt (**9a**, **9b**). Whereas, the stretching vibration of the C=C bond in both organic salt appears at  $1675\text{ cm}^{-1}$  and  $1635\text{ cm}^{-1}$  (Figure 1). Besides, peaks at  $2900$  and  $2800\text{ cm}^{-1}$  belonging to hydrogen stretching (Türkçü, 2016).

Also, NMR spectroscopy confirmed the formation of organic salt (**9a**, **9b**). The signals belong to the aromatic protons of alkoxy benzoate unit in both compounds shift to (7.8, 6.7) ppm and (7.9, 6.75) ppm respectively as compared with the signals of pure 4-DBA at (8.05, 6.95) ppm, due to increase in electron density of aromatic ring. Similarly, the signals of oxymethylene protons of 4-DBA in ion complex shift to higher field 3.8 ppm and 3.75 ppm as compared with the signals of pure 4-DBA at 4.05 ppm (Figure 2). Additionally, the singlets of aromatic ring protons in organic salt (**9a**, **9b**) didn't show any shifting due to their electronic environment did not change. These changes in chemical shift related to the difference in electron density after the interaction.

However, the  $^{13}\text{C}$  NMR spectra show that the carbonyl carbon of 4-DBA shifted from 171.6 to 165.12 ppm, similarity the aromatic carbon next to alkoxy group of 4-DBA shift slightly from 163.69 to 163.6 ppm. These change in chemical shift due to decrease of electron density after the ionic interaction (Figure 3). Additionally, the peaks which belong to triazine ring didn't show any shifting.

Additionally, the mass spectrometry of organic salt (**9a**) confirmed the molecular structure by the presence of  $(M+3K)^{+3}$  at 678.70 peaks, which correspond to  $\text{C}_{124}\text{H}_{159}\text{N}_9\text{O}_9$ , similarity the molecular structure of organic salt (**9b**) confirmed by the presence of  $(M+3K)^{+3}$  peaks at 680.36 and 680.03, which correspond to  $\text{C}_{121}\text{H}_{156}\text{N}_{12}\text{O}_9$ , (Figure 4).

Compound 4-DBA, which has a terminal chain, and already shows liquid crystalline, so to obtain liquid crystalline material for our synthesized compounds, the equimolar mixture between six-

armed  $\pi$ -conjugated system and 4-DBA was obtained through ionic interaction. Concerning to 4-DBA, upon heating showed three peaks corresponding to Cr-SmC-N-Iso transitions. On cooling from isotropic phase, the same behavior of reverse transitions was observed. In addition to this, a calorimetric peak corresponding to Cr-Cr transition at  $65.86^\circ\text{C}$  was detected in cooling DSC thermogram (Kumar, 2010; Pisupati, 2000).

The equimolar mixtures of the organic salt (**9a**, **9b**) based on the benzene core were investigated by using an optical polarizing microscope (PM) and differential scanning calorimeter (DSC). The compounds (**9a**, **9b**) show one endotherm corresponds to crystal to the isotropic (Iso) transition in heating DSC thermogram. The organic salts (**9a**, **9b**) show no liquid crystal behavior by an optical polarizing microscope (PM) observation.

The organic salt (**9a**, **9b**) exhibit a phase transition sequence of Cr-Col-Iso, which is in agreement with two endotherms in DSC heating curves. Compound (**9a**) on cooling from the isotropic liquid, exhibited one peak in phase transition with the dendritic growing texture was observed between  $(64-18)^\circ\text{C}$ , whereas compound (**9b**) phase transition with the growing dendritic texture was observed between  $(71-20)^\circ\text{C}$ , (Figure 5). Both organic salts with multi-side chains, the differential scanning calorimetry, and optical polarized microscope showed no liquid crystal behavior.

#### 4. CONCLUSIONS:

New six arms macromolecular structures was efficiently prepared which composed of 1,3,5-trichlorobenzene central core, three armed of 2-Ethynylpyridine (2-Ethynylbenzene), and three armed of 1,3,5-triazine rings carrying dodecyloxy chains which are positioned at the peripheries of the central core by acetylenic bridges. The six-armed compounds was non liquid crystal therefore the compounds were mixed with 4-dodecyloxy benzoic acid to obtain organic salt. The organic salts, which made between the  $\pi$ -conjugated system and 4-dodecyloxy benzoic acid were investigated for their liquid crystal properties by optical polarizing microscope (POM) and differential scanning calorimetry (DSC), it's found no liquid crystalline behaviours even after ionic interaction through hydrogen bonding. All the synthesized compounds were confirmed by spectroscopic analyses ( $^{13}\text{C}$  NMR,  $^1\text{H}$  NMR, FT-IR, and HRMS).

## RESUMO

O pensamento crítico é a capacidade de pensar racional e reflexivamente sobre o que deve ser feito ou acreditado. Essa habilidade permite tomar decisões lógicas, com base nas informações obtidas e processadas de acordo com a habilidade. O desenvolvimento de habilidades de pensamento crítico na aprendizagem é importante porque permite que os alunos lidem efetivamente com problemas sociais, científicos e práticos. Portanto, esta pesquisa teve como objetivo descrever a efetividade da aprendizagem baseada em problemas para melhorar as habilidades de pensamento crítico dos alunos para lidar com informações fraudulentas em química. Esta pesquisa foi realizada utilizando um grupo controle e outro experimental. Os dados foram coletados de 60 alunos do 11º ano do ensino médio da província de Lampung, na Indonésia, e analisados pelo SPSS versão 23.0. A efetividade da aprendizagem baseada em problemas foi mensurada com base no ganho *n*. O valor de ganho *n* das classes experimental e controle foi de 0,709 (alto) e 0,332 (médio), respectivamente. Os resultados indicaram que a aprendizagem baseada em problemas facilitou e é eficaz para melhorar as habilidades de pensamento crítico dos alunos.

**Palavras-chave:** *habilidades de pensamento crítico; informações fraudulentas; aprendizagem baseada em problemas; aprendizagem prática*

## ABSTRACT

Critical thinking is the ability to think rationally and reflectively about what must be done or believed. This skill allows one to make logical decisions based on information obtained and processed according to ability. The development of critical thinking skills in learning is essential because they enable students to deal effectively with social, scientific, and practical problems. Therefore, this research aimed to describe the effectivity of problem-based learning to improve students' critical thinking skills to deal with hoax information in chemistry. This research was carried out through the control and experimental groups. Data were collected from 60 the 11<sup>th</sup>-grade students of the State High School in Lampung Province, Indonesia, and analyzed by using SPSS version 23.0. The effectivity of problem-based learning was measured based on the *n*-gain. The *n*-gain value of experimental and control classes was 0.709 (high) and 0.322 (medium), respectively. The results indicated that problem-based learning has facilitated and effective to improve students' critical thinking skills.

## 1. INTRODUCTION:

The world is now in the era of the industrial revolution of 4.0. In this era, there was a rapid development of science and technology, both censorship, interconnection, and data analysis, thus bringing up ideas to be integrated into various fields of industry. Due to the fast development of science and technology, the problems faced are increasingly numerous and complex. On the other hand, the 4.0 industrial revolution will affect not only the industry, but also the labor market (Van den Bergh *et al.*, 2006; Lowden *et al.*, 2011; Danczak, Thompson, and Overton, 2020). Workforce needs have been transformed from routine work to shift to non-routine work (Trilling and Fadel, 2009). Because of this, a problem solver is needed to overcome them.

As a problem solver, knowledge alone is not enough to deal with increasingly complex problems in the current disruptive era. The contemporary job market demands the production of someone who can work in a disruptive and ill-defined environment, face non-routine and abstract work processes, make decisions, take responsibility, and work in teams (Van den Bergh *et al.*, 2006; Baygin *et al.*, 2016; Diawati *et al.*, 2017; Diawati *et al.*, 2018; Fadiawati, Diawati, and Syamsuri, 2019). This ability is related to skills demanded in the 21st century, one of which is critical thinking skills (CTS).

Critical thinking (CT) is rational and reflective thinking with an emphasis on making decisions about what to believe and do (Norris and Ennis, 1989). Based on the Delphi Report, CT is self-regulation in deciding which has goals that produce interpretations, analyzes, evaluations and inferences as well as concrete, conceptual explanations, as well as having methods, criteria or contextual considerations on which these decisions are based (Facione, 1990; Dwyer, Hogan, and Stewart, 2014; Stephenson and Sadler-McKnight, 2016).

The development of CTS has been the main focus of several researchers (Halpern, 2014; Moore, 2015; Butler and Halpern, 2020; Danczak, Thompson, and Overton, 2020). CTS is important because they enable students "to deal effectively with social, scientific, and practical problems" (Shakirova, 2007). Some cognitive psychology researchers report that CTS could be developed within a variety of discipline areas to make knowledge retrieval easier. McMillan (1987) argued that standalone and integrated courses were equally successful in developing CTS. On the other hand, Ennis (1990) accepted that CTS

also could be effectively improved with or without discipline-specific areas. Davies (2013) agreed that CTS is a fundamental skill at the basis of all disciplines of knowledge. CTS can be a need to accommodate the discipline-specific needs in higher education. CTS could be transferred to situations encountered in daily life (Butler and Halpern, 2020); one of them is about hoax information circulating through social networks.

Facebook, Youtube, WhatsApp, dan Instagram are social networks that are widely accessed by internet users. Among social networks, Facebook users number 2.414 billion, while Youtube with 2 billion active users, WhatsApp users number 1.6 billion, and Instagram with 1 billion active users (Clement, 2020). Fellow social networks users share a variety of news broadcasts dan information. Other users can quickly see both.

However, not only real news and information but also fake and mislead (hoax) news and information shared. Hoax information was made based on individual opinions that cannot be accounted for, and they shared in a chain through social networks. Related to circulating hoax information, CTS is needed in media literacy. Some learning models which suggested to developing CTS in chemistry are problem-based (Kek and Huijser, 2011; Martyn *et al.*, 2014), open-ended practical (Klein and Carney, 2014), and inquiry (Gupta *et al.*, 2015).

In this article, it is described the results of developed CTS dealing with hoax information by using problem-based learning (PBL). Fogarty (1997) defines PBL as a learning model that deals with real-life or real-world problems that are ill-structured, open-ended, and ambiguous. In these learning, students are faced with hoax information problems related to some food and drinks circulating through social networks. For example, hoax information received by the public is related to noodles and carbonated water. Based on information flowing, noodles and carbonated water are considered poisonous and dangerous. This is because if noodles with iodine drop, they will turn purple. On the other hand, carbonated water contains high levels of acid so that it can dissolve bones and teeth.

This corresponds with the outbreak of hoax information in Indonesia has become a national problem. The survey results of the Indonesian Telematics Society (2019) that a variety of hoax information that is often accepted by the public. Some of them are issues about health by 40.70%, issues about food and drinks by 30.00%, and

issues about science and technology by 20.00%. As a result of the circulation of the hoax information, the community became restless and was overtaken by excessive fear (Zuria and Suyanto, 2018). On the other hand, noodles and carbonated water producers suffer losses due to competition and trademark pollution (Apriyani, Fadiawati, and Syamsuri, 2017).

Furthermore, based on the hoax information in circulation, students look for information from reliable sources, conduct investigations, and use their knowledge and to be analyzed and confirm whether the information can be trusted or not. Therefore, this research aimed to describe the effectivity of PBL to improve students' CTS to deal with hoax information in chemistry.

## 2. MATERIALS AND METHODS:

This research is a quasi-experimental and carried out in the State High School in Lampung Province, Indonesia, by using nonequivalent control-group design (Creswell and Creswell, 2017). The population of this research is the 11<sup>th</sup>-grade students totaling 200 students. By using purposive sampling obtained 60 students, and every one declares to agree to participate in this research. Furthermore, students are grouped into experimental and control classes. Purposive sampling is done with consideration to obtain samples with the same or relatively similar characteristics based on prior information of a population (Fraenkel, Wallen, and Hyun, 2011).

Before the intervention, both the experimental and control classes were given pretest Norris-Ennis's CTS in the form of open-ended questions (Appendix 1). Next is the intervention stage by applying PBL in the experimental class and conventional learning in the control class.

Learning begins by orienting students to the hoax information problems. In the organized students' phase, students are asked to gather information related to the problem. Furthermore, students make investigation design and apply it to confirm whether or not the hoax information is being faced. Data obtained are then presented. In the last phase, students will be asked and answered on the work between groups to bring up various opinions or ideas. The learning process is guided by student worksheets to match the PBL syntax. During the learning process, student performance is also assessed. At the end of the learning, both classes were given a post-test Norris-Ennis's CTS in the form of open-ended

questions.

Statistical testing with SPSS version 23.0 was carried out on the results of the pretest through normality (One Sample Kolmogorov-Smirnov's Test), homogeneity of variance (Levene's Test), and independent sample t test. Increasing the score of each class (n-gain) also statistically tested through normality and One Way ANOVA. The n-gain categorized as high, medium, or low (Hake, 1998).

## 3. RESULTS AND DISCUSSION:

### 3.1. Results

Average scores of the pretest and post-test students' CTS were presented in Figure 1. Table 1 informed the results of the statistical analysis of the pretest score where the significance value (sig. > 0.05) indicates that average scores of the pretest come from populations that were normally distributed and have homogeneous variances. Based on the significance value (sig. > 0.05) on the independent sample t-test results obtained information that there was no difference between average scores of the pretest in the two classes.

**Figure 1.** The average scores of pretest and post-test students' CTS.

The average n-gain of the experimental and control classes was presented in Figure 2.

**Figure 2.** The average n-gain students' CTS.

Based on Table 2, normality test results for n-gain indicate that the significance value obtained (sig.) was greater than 0.05. This indicates that the average n-gain of CTS comes from a normally distributed population. One Way ANOVA test results show the significance value obtained was less than 0.05. Thus it could be said that there is a difference between the average n-gain of CTS between the experimental and control classes. Based on the significance value (sig. <0.05) on the independent sample t-test results obtained information that n-gain average of the experimental class was higher than the control class.

### 3.2. Discussion

The above description informs that the PBL model was effective in improving students' CTS compared to conventional learning. Students' CTS were trained at each stage of problem-based learning guided by student worksheets.

#### 3.2.1 Phase 1, Student Orientation to the Problems

At this phase, students were faced with a problem related to hoax information circulating in the community packaged into the discourse. The discourse contains information that instant noodles contain poisons that harm the body. If noodles with iodine drop, they will turn purple. In a different discourse also informed that carbonated water contains acids that can clean the toilet and iron rust. When taken by mouth, the acid content is illustrated will mix and react with gastric acid in

the stomach. This makes people who used to consume both noodles and carbonated water uneasy. Regarding their information and understanding of discourse were presented in Figures 3 and 4 (the authentic source was available in Appendix 2). Based on this, this phase trains students' CTS.

**Q: What information do you know based on the discourse above?**

A: 1) Instant noodles contain free radicals which are proven by changes in color when dipped in iodine solution  
2) Instant noodles are dangerous because they are made from chemicals

**Q: What information do you not know based on the discourse above?**

A: The content of instant noodles

**Figure 3.** Students' understanding of the discourse of the danger of noodles.

**Q: What information do you know based on the discourse above?**

A: 1) Carbonated water are dangerous to consume because they contain acids that can clean iron rust and toilets  
2) Carbonated water added to glasses filled with clear liquid turn into chocolate foam, it is possible the same thing happens in our stomach

**Q: What information do you not know based on the discourse above?**

A: The content of carbonated water

**Figure 4.** Students' understanding of the discourse of the danger of carbonated water.

After students understand the problem critically, students were asked to formulate the main questions critically. Based on discourse, students should first consider the truth of the information. In the 1<sup>st</sup> worksheet, several students wrote question statements that do not fit the content of the discourse. A similar thing happened in the 2<sup>nd</sup> worksheet. Some students were not confident and were doubtful about the formulation of the questions they asked. The following were some of the questions written by students in Figures 5 and 6 (the authentic source was available in Appendix 2).

In learning, the formulation of the main questions raised was not appropriate to the problems listed in the discourse. Related to this, the teacher guided the students to determine the

main question of the air following late to the content of the discourse. Based on the direction was given by the teacher, students improved the statement of question formulation in the 1<sup>st</sup> and 2<sup>nd</sup> worksheets, as shown in Figure 7 and Figure 8 (the authentic source was available in Appendix 2).

#### Question Statement

- 1) Why instant noodles are still being sold in the market?
- 2) Why did the instant noodles dip in iodine solution turn purple?

**Figure 5.** Question statement in the 1<sup>st</sup> worksheet is not appropriate to the content.

#### Question Statement

- 1) Why carbonated water are still being sold in the market?
- 2) Why carbonated water can be used to clean toilets?

**Figure 6.** Question statement in the 2<sup>nd</sup> worksheet is not appropriate to the content.

#### Question Statement

- 1) Is it true that instant noodles are dangerous if consumed?
- 2) What are the ingredients of instant noodles?
- 3) Why do instant noodles turn purple when dipped in an iodine solution?
- 4) What chemicals are contained in instant noodles?
- 5) Do instant noodles contain free radicals?

**Figure 7.** Question statement in the 1<sup>st</sup> worksheet, which has been fixed.

#### Question Statement

- 1) Is it true that carbonated water are harmful to the body?
- 2) Is it true that information that carbonated drinks can be used to clean toilets?
- 3) What are the compositions contained in carbonated water?
- 4) Why carbonated drinks can clean iron rust?
- 5) What acid compounds are contained in carbonated water?

**Figure 8.** Question statement in the 2<sup>nd</sup> worksheet, which has been fixed.

Based on the improvement of the question

statement raised information obtained that students could critically determine the problems that exist in the discourse. Besides, students were increasingly skilled in making questions related to discourse.

In this study, the skills to understand the problems given critically could be said to increase. An increase in skills to understand the problem critically was also supported by student activities in learning. Students were frequently seen asking questions and giving their opinions. Therefore, PBL could increase information literacy, one of which was identifying issues or problems faced (Chu, Tse, and Chow, 2011).

### 3.2.2 Phase 2, Organize Students

To answer the questions that have been asked, students were asked to gather information from various sources relevant to the discourse. In its completion, students were guided by an assignment sheet. There were two activities, namely defining the problem and organizing learning tasks related to discourse, as well as gathering appropriate information so that they can submit hypotheses. Students in groups were given three days to define the problem and collect information along with the source. The same thing was done in the 2<sup>nd</sup> worksheet.

By teacher's guide, students answered the formulation of questions by finding and gathering information related to the problem, including: (1) the content contained in instant noodles and beverage drinks; (2) information about the color changes that occur in instant noodles after dipped in a solution of iodine and pH in carbonated drinks; (3) information about any food ingredients that have a content that is not much different from instant noodles or drinks or solutions that have a pH not much different from carbonated drinks. Through these activities, students were expected to be able to sort out relevant and trusted information in solving problems carefully. Accordingly, this phase trains the skills to gather relevant information. The results of the assignments were presented in Figures 9 and 10 (the authentic source was available in Appendix 2).

During these activities, students were asked to report the results of the task to the teacher periodically. The teacher evaluated the assignment and given direction when there was less relevant information, and the source was not credible. For this advice, students made improvements and obtain information on the 1<sup>st</sup> worksheet, among others: (1) the content

contained in instant noodles, (2) the content contained in the iodine, (3) carbohydrate testing, and (4) the cause of the occurrence discoloration of instant noodles after dipping the solution of iodine. On the other hand, information obtained in the 2<sup>nd</sup> worksheet includes: (1) the content contained in carbonated water, (2) the acidity of carbonated water, (3) buffering solutions in the blood, and (4) metal corrosion.

#### Assignment Sheet

**Q: Find information from various sources regarding the content of instant noodles!**

A: content of instant noodles: carbohydrates, fats, proteins, cholesterol, sodium, vitamins, calcium, iron

**Q: Find information from various sources regarding the color change in iodine-dripped instant noodles!**

A: discoloration of instant noodles that are dropped with iodine indicates carbohydrate content

**Q: Find information from various sources about some food ingredients that have the same content as instant noodles!**

A: rice, bread, corn, potatoes

**Figure 9.** Information obtained by students related to instant noodles.

#### Assignment Sheet

**Q: Find information from various sources regarding the composition of Cola!**

A: content of cola: carbonated water, sugar, caramel coloring, phosphoric acid, caffeine, citric acid

**Q: Find information on the pH of carbonated water!**

A: Carbonated water has a pH = 3

**Q: Find information on types of drinks or solutions whose pH is the same as carbonated water!**

A: lime juice, vinegar, tamarin juice, lemon juice

**Figure 10.** Information obtained by students related to carbonated water.

Based on observations, at first, students still found it difficult to sort out credible and

relevant information, especially if it was connected with chemical material. Most of the students' answers contain general things and not following the learning objectives, as well as information questions about food in the form of macromolecules that are absorbed by the nutritional content, students answer "protein and carbohydrate" without knowing that there are still many nutrients that are absorbed by the body. This might be due to a lack of understanding of problems and questions and accustomed to taking information from web blog sources, news, or literature whose clarity has not been proven.

To overcome this, a discussion was held for 25 minutes, in turn, eight groups consulted about students' answers with the teacher, so that information was obtained following problem-solving. In consultation activities, the teacher directed students' answers to solutions related to chemical materials, and the answers obtained were the nutrient content absorbed by the body, including "glucose, amino acids, vitamins and minerals, and water." To convince students, then the teacher invited students to conduct a literature study on other people's research related to the nutrient content absorbed by the body. This activity could indirectly train students' CTS, especially on indicators considering the credibility of the source.

CTS could be done by figuring out what to believe or what to do and doing it reflectively and reasonably (Ennis, 1990). Therefore, to obtain reliable information, students must conduct investigative activities to obtain appropriate conclusions so that meaningful construction of knowledge does not occur.

#### 3.2.3 Phase 3, Individual and Group Research Guide

In the 1<sup>st</sup> worksheet, an experiment was carried out on a carbohydrate test on several foods with a solution of iodine. Investigation activities require students to be actively involved and train students in their opinions to get explanations and problem-solving. Something that is not much different was done in the 2<sup>nd</sup> worksheet regarding the removal of rust on iron with a solution or drink that has the same pH or almost the same as carbonated water.

Before investigation activities were carried out through experimental activities, students were required to make experimental designs. The intended experimental design includes: (1) identifying variables; (2) controlling variables; (3) compile experimental procedures; (4) identifying

tools and materials used; and (5) design an observation table (Fadiawati and Syamsuri, 2016; 2018). The experimental design was then consulted with the teacher. Based on the direction given by the teacher, students improved the design of the experiment.

Furthermore, students conducted experiments based on the results of experimental designs. In the 1<sup>st</sup> worksheet, students were asked to compare colors in instant noodles before and after dipping in iodine solution. In the 2<sup>nd</sup> worksheet, students were directed and guided to conduct experiments, ranging from measuring the volume of each solution as much as 10 mL, match by using universal indicators, comparing the amount of rust on nails that have been immersed in each solution for 10 minutes. Investigative activities through practicum make the learning process of students more meaningful (Hodson, 1990; Garnett, Garnett and Hacking, 1995; Hofstein and Lunetta, 2004; Hofstein and Mamlok-Naaman, 2007; Abrahams and Millar, 2008).

Faced this situation, students were required to be critical and careful in observing each process and the results obtained during the experiment to be able to conclude precisely and reasonably. On the other hand, through this activity students will get used to working together in groups so that it will foster a disciplined, honest, and thorough attitude in conducting learning activities and group discussions. Diawati *et al.* (2018) suggest that when students are assigned to work on worksheets and undertake learning activities and group discussions, students practice working together between group members to discuss the tasks contained in worksheets. Through this group discussion, students exchange opinions, assess the views of friends regarding problems correctly.

### **3.2.4 Phase 4, Develop and Present the Work**

After conducting an investigation and experiment, students were then asked to develop and present their work in the form of observations during the experiment which are then submitted to the teacher. Furthermore, students wrote the experimental data, answered questions that were challenging related to the experimental data to be able to develop ideas or ideas by linking the results obtained during the experiment with various information that they have obtained from various sources, and reported the solution obtained as a work.

In the initial phases of developing and presenting the results of an experiment, students have not been very active in discussions to

analyze the results of experiments and draw conclusions. To overcome this, the teacher provided guidance and checks the work of students in each group if there are difficulties. At the next meeting, it was seen that students were increasingly actively discussing and even asking critical questions to the teacher. Students' inference skills have improved.

In this condition, when students were assigned to work on a worksheet with their study groups, students practiced being able to work together between group members to discuss the tasks contained in worksheets. Through discussion activities, students exchanged opinions, assess the opinions of friends, or reject or accept the opinions of friends so that they are expected to be able to give the right conclusions. Thus, student activities in doing assignments, working together, and discussing supported the improvement of students' CTS.

Syamsuri and Fadiawati (2019) revealed that inference means identifying and obtaining the elements needed to draw acceptable conclusions. Inference skills can be trained in the stage of developing and presenting work. At this stage students also do information processing to find the linkage of one information with other information, so students can conclude the linkages of that information.

### **3.2.5 Phase 5, Analyze and Evaluate the Problem-Solving Process**

In the last phase, student learning outcomes were evaluated in terms of the material learned and ask each group to communicate their work. In this way, students will be asked and answered on the work between groups to bring up various opinions, or ideas, such as the use of used plastic cups instead of chemical cups. Thus they will be understood the problem more deeply and can be developed ideas more broadly.

Through PBL, students were trained to be able to formulate the main questions. Students were also required to gather the information needed to confirm the truth of information circulating based on discourse. In searching for information, students were trained to choose sources that are relevant and credible, so that the information they get could be trusted, and then students can make inferences (Syamsuri and Fadiawati, 2019). Through investigation activities, students could determine what actions should be taken to confirm the truth of information circulating based on discourse. In presenting the work, could bring up various ideas. Students were also able to

communicate their work to others. With this learning phase, students' CTS could certainly be trained (Dehkordi and Saeed, 2008; Fadiawati, Diawati, and Syamsuri, 2019; Hung and Amida, 2020).

#### 4. CONCLUSIONS:

By using PBL to deal with the circulating hoax information, students look for information from reliable and credible sources, conduct investigations, and use their knowledge and to be analyzed and confirm whether the information can be trusted or not. Additionally, the n-gain value of the experimental class in high categorized, while the n-gain value of the control class in medium categorized. Therefore, it could be said that PBL applied in this research has facilitated and effective in improving students' CTS.

## APPENDIX 1

### Pretest Questions

#### DISCOURSE 1

Read the following discourse to answer the questions below!

Have you ever seen a viral video on Youtube (<https://www.youtube.com/watch?V=dUGndfBS5Fk>) about an experiment of instant noodles with iodine drop? What will happen after a few minutes? It turns out that instant noodles immediately change color to purple.

The following information is obtained from Facebook (<https://www.facebook.com/91201988700/posts/temanstaukah-kalian-kalau-mie-instan-mandung-radikal-bebas-yang-sangat-berbah/10153784538233701/>) In the news was informed that instant noodles contain free radicals which are very dangerous for the body. This is proven by dipping instant noodles in the iodine solution. The result is a color change in instant noodles to purple. The change in color indicates that instant noodles contain negative toxins derived from chemicals.

Based on this discourse, answer the following questions!

1. **CTS indicator: understanding the problems critically.**  
Do you believe the information in the discourse above? Explain with reasons!
2. **CTS indicator: making the questions.**  
Ask questions related to the discourse above, regarding:
  - a. main question
  - b. questions besides the main questions
3. **CTS indicator: collecting and considering the pieces of information.**  
What information do you need to answer the questions you ask

#### DISCOURSE 2

Read the following discourse to answer the questions below!

Coke Cola is a carbonated drink that tastes good when thirsty. Almost all people like this drink. But lately, there has been information circulating on social media such as Youtube, Whatsapp, Facebook, Twitter, and Instagram that illustrates the dangers of carbonated drinks when mixed with stomach acid. On social media Youtube (<https://www.youtube.com/watch?v=ISGJkA1T8fY>), a video is displayed when a colorless liquid in a glass container is added with carbonated drinks. When the two are mixed, it turns out to react to form a blackish-brown froth which over time looks solid. The uploader of the video illustrates the same thing would happen if carbonated drinks in the stomach were mixed with gastric acid.

There are also other videos on social media Youtube (<https://www.youtube.com/watch?v=Zj1MXEZ-90M>) that shows the use of carbonated drinks as a toilet cleaner. On social media Youtube ([https://www.youtube.com/watch?v=KYcVJt6\\_cSQ](https://www.youtube.com/watch?v=KYcVJt6_cSQ)) also shows videos related to the use of carbonated drinks to clean iron rust. The use of carbonated beverages as a toilet cleaner and iron rust is associated with the acid content in the drink.

The videos then spread sequentially through Whatsapp, Facebook, Twitter, and Instagram. The distribution of the videos is accompanied by information that illustrates the dangers of carbonated drinks. As a result, many people assume that carbonated cola drinks are very dangerous for the body because they are made from hazardous chemicals.

Based on this discourse, answer the following questions!

4. **CTS indicator: understanding the problems critically.**  
Do you believe the information in the discourse above? Explain with reasons!
5. **CTS indicator: making the questions.**  
Ask questions related to the discourse above, regarding:
  - a. main question
  - b. questions besides the main questions
6. **CTS indicator: collecting and considering the pieces of information.**  
What information do you need to answer the questions you ask

### RESUMO

Os depósitos marinhos da Formação Qom, que é um importante reservatório de gás no Irã Central com a idade do Oligoceno Inicial ao Mioceno Inicial, são estudados para determinar fácies, paleoambiente sedimentar e seqüências deposicionais. A litologia primária é o calcário, que é acompanhado por um conglomerado, marga arenosa, marga e calcário arenoso. Com base no conteúdo siliciclástico, na análise textural e nos constituintes bióticos, dez fácies foram identificadas. Essas fácies pertencem a cinco locais deposicionais, incluindo delta, enseada de maré, lagoa, cardume e mar aberto. De acordo com a ausência de recifes de barreira contínuos e grandes, variação vertical gradual das fácies do ambiente de transição (delta) para o mar aberto raso, a ausência de grãos oncoídes, pisóides e agregados que estão principalmente presentes em ambientes com prateleiras de carbonato com aros, a ausência de calciturbiditos e estruturas de queda e deslizamento, a Formação Qom foi depositada em uma rampa homoclinal (rampa interna, média e externa). Estudos de campo e arquitetura de variação vertical de fácies no âmbito de sistemas deposicionais levaram ao reconhecimento de duas seqüências deposicionais de 3ª ordem no tempo do Mioceno Primitivo (Aquitânico). Fácies sedimentares na Formação Qom que ocorreram principalmente no meio da rampa revelam um padrão de empilhamento principalmente agregado nas seqüências deposicionais. A arquitetura estratigráfica das seqüências do Mioceno Primitivo da Formação Qom, com base em gráficos de correlação, é semelhante às seqüências regionais da placa da Arábia e da bacia de Zagros.

**Palavras-chave:** *Facies, Paleoambiente sedimentar, Estratigrafia de seqüências, Aquitânico, Formação Qom*

### ABSTRACT

Marine deposits of the Qom Formation, which is an important gas reservoir in Central Iran with the age of Early Oligocene to Early Miocene, is studied to determine facies, sedimentary paleoenvironment, and depositional sequences. The primary lithology is limestone, which is accompanied by a conglomerate, sandy marl, marl, and sandy limestone. Based on siliciclastic content, textural analysis, and the biotic constituents, ten facies have been identified. These facies belong to five depositional settings, including delta, a tidal inlet, lagoon, shoal, and open marine. According to the absence of continuous and large barrier reefs, gradual vertical variation in facies from the transitional environment (delta) to shallow open marine, the absence of oncoid, pisoid and aggregate grains that are mostly present in rimmed carbonate shelf environments, the absence of calciturbidites and slump and slide structures, the Qom Formation has been deposited in a homoclinal ramp setting (inner, middle and outer ramp). Field studies and vertical facies variation architecture in the framework of depositional system tracts led to the recognition of two 3rd order depositional sequences in the Early Miocene (Aquitanian) time. Sedimentary

facies in the Qom Formation that mainly occurred in the middle ramp setting reveal a mostly aggradational stacking pattern in depositional sequences. The Early Miocene sequences stratigraphic architecture of the Qom Formation based on correlation charts are similar to the regional sequences of the Arabian plate and Zagros basin.

**Keywords:** *Facies, Sedimentary paleoenvironment, Sequence stratigraphy, Aquitanian, Qom Formation*

## چکیده

نهشته‌های دریایی سازند قم به سن اوایل الیگوسن تا اوایل میوسن که یک مخزن گازی بزرگ در ایران مرکزی را تشکیل می‌دهد به منظور تعیین رخساره‌ها، محیط رسوبی دیرینه و چینه‌نگاری سکانشی مورد مطالعه قرار گرفت است. سنگ‌شناسی اصلی در این رخنمون‌ها شامل سنگ آهک است که با لایه‌هایی از کنگلومرا، مارن، مارن ماسه‌ای و سنگ آهک ماسه‌ای همراه است. در منطقه مورد مطالعه بر اساس میزان مواد تخریبی ورودی به حوضه، آنالیز بافت رسوبی و محتوای فسیلی ده رخساره شناسایی گردید. این رخساره‌ها در پنج جایگاه نهشته‌ای شامل دلتا، تاییدال اینلت، لاگون، شول و دریای باز نهشته شده‌اند. شواهدی نظیر عدم حضور ریف‌های سدی بزرگ و فاقد تداوم جانبی، تغییرات تدریجی رخساره‌ها در جهت قائم از محیط انتقالی (دلتا) تا دریای باز، عدم حضور دانه‌های آنکوئیدی، پیژوئیدی و دانه‌های اگرگاتی که خاص شلف‌های کربناته بوده و با به ندرت در رمپ‌ها یافت می‌شوند و در نهایت عدم مشاهده کلسی‌توربیدایت‌ها و ساختارهای ریزشی و لغزشی، تاییدی بر نهشت سازند قم در منطقه مورد مطالعه در یک پلاتفرم رمپ هموکلینال از رمپ داخلی تا رمپ میانی و خارجی است. مطالعات صحرایی به همراه نحوه تغییرات رخساره‌ها در چارچوب سیستم تراکت‌های نهشته منجر به شناسایی دو سکانش رسوبی درجه سوم به سن اکتانین در سازند قم گردید. الگوی برانبارش جمعی در سکانش‌های نهشته سازند قم که رخساره‌های رسوبی در آن به طور عمده در محیط رمپ میانی نهشته شده‌اند، غالب است. سکانش‌های نهشته سازند قم به سن اکتانین در برش‌های مورد بررسی دارای مطابقت بالایی با سکانش‌های رسوبی شناسایی شده در حوضه زاگرس و پلیت عربی با سن مشابه است.

**کلیدواژه‌ها:** رخساره، محیط رسوبی دیرینه، چینه‌نگاری سکانشی، اکتانین، سازند قم

## 1. INTRODUCTION:

Tectonic activities cause the on-going volcanism during the Late Eocene in Central Iran. These activities led to a regional unconformity in the base of Oligocene deposits (Stocklin and Setudehnia, 1991). This unconformity is overlain by evaporitic and siliciclastic deposits of the Lower Red Formation formed by Late Eocene and Early Oligocene epirogenic movements in Central Iran. Following these marine deposits of the Qom Formation, which is a crucial gas reservoir in Central Iran, is formed with raising of sea-level and a transgression in the Early Oligocene Sea, which lasts till the Early Miocene (Dozy, 1955). The Qom Formation marl, limestone, and siliciclastic rocks have been overlain and underlain with an unconformity by continental deposits of the Lower Red and Upper Red formations, respectively (Stocklin and Setudehnia, 1991; Reuter *et al.*, 2009). The well-known fractured reservoir of the Asmari Formation is isochronous with the Qom Formation (Motiea, 1993).

No type section has been introduced for the Qom Formation, but a type area has been defined for this formation in the Qom Plain in Central Iran microplate (Aghanabati, 2011). In Central Iran, the Qom Formation is deposited with variation in lithostratigraphy, biozone, and microfacies characteristics. The Qom Formation is Oligocene-Miocene in age, based on larger benthic foraminifera biostratigraphy by Yazdi-Moghaddam (2011).

A stratigraphic sequence correlation

between the Qom Formation succession and its comparison with isochronous formations in adjacent areas can explain the depositional model and transgression of the Tethyan Seaway in Central Iran. Since the Qom Formation is a gas reservoir formed in a back-arc basin, this study can help to understand the characteristics of these deposits in the Middle East.

Biostratigraphy of the Qom Formation in this study has been reported as the Lower Eocene age (Aquitanian) by Maghfoori-Moghaddam and Yasboulaghi (2015). The purpose of this research is to describe the depositional setting of the Qom Formation, sequence stratigraphy, and its correlation with the Oligocene-Miocene Asmari Formation in the Zagros Basin.

## 2. GEOLOGICAL SETTING AND LOCATION OF THE STUDY AREA:

The final collision of the African-Arabian Plate with the Iranian plate, which began in the Mesozoic, formed the microplate of Central Iran (Coleman-Sadd, 1982). The closure of the Neotethys during the Miocene time was the result of the collision of these plates (Harzhauser and Piller 2007, Reuter *et al.*, 2009). This collision has also formed the Sanandaj–Sirjan Basin (a fore-arc basin), Urumieh–Dokhtar magmatic arc (an intra-arc basin), and the Qom Basin (a back-arc basin) as a result of the Zagros oceanic crust (Neotethys) and southwestern Iranian cratonic plate subduction at the north-eastern margin of the Neotethys on the Iranian Plate (Figure 1a). A

volcanic arc system that developed during the Eocene series has separated these basins (Stocklin and Setudehina, 1991). Thus, during the Late Oligocene-Early Miocene, the Qom Formation was deposited in this back-arc basin in the central and northern part of the central Iran microplate (Berberian, 1983). The age, thickness, and lithology of the Qom Formation vary in different sections. These are caused respectively by (1) marine transgression of the Neoethys in the Iranian Plate started from the southeast and continued northwestward gradually, and (2) various positions of the Qom Formation within the Qom back-arc basin (Schuster and Wielandt 1999). Furthermore, the thickness and lithofacies variations seen within the Qom Formation may have controlled regional faults and subsidence and uplift in the Qom basin (Nogol-e-Sadat, 1985).

In this research, two sections have been investigated in the northwestern margin of the back-arc basin of the Qom Basin in Markazi Province. The study sections include Ashtiyan and Kordijan, which are located in north and northeast of Ashtiyan, about 67 km north of Arak City in central Iran (Figure 1b). The Ashtiyan section at the geographic location of 34°32'45"N and 50°01'18"E and the Kordijan section occurred at 34°38'09"N and 50°07'23"E are examined in detail for sedimentological investigation. In these sections, thick to medium and thin-bedded limestone with a few argillaceous limestone beds and marl formed the main lithologies. Some units consist of conglomerate, sandy marl, and sandy limestone that are minor lithologies. In both sections, the Qom Formation is unconformably underlain by the Oligocene Lower Red Formation and overlain by the Miocene Upper Red Formation (Figure 1c and Figure 2).

### 3. MATERIALS AND METHODS:

The complete sections of the Qom Formation in Ashtiyan and Kordijan were measured and sampled in the Ashtiyan area in north of Markazi Province. In the Kordijan section, with a thickness of 94 m, thirty-four samples have been collected. The thickness of the Ashtiyan section is 103 m, and 25 samples have been studied. The classification of the carbonate rocks is based on Dunhan (1962). The siliciclastic rocks follow the nomenclature of Folk (1980). The composition percentage of allochems in sedimentary rocks is based on the Bacelle and Bosellini (1965) visual diagrams. Samples are stained by potassium ferricyanide and alizarin red-s to distinguish carbonate minerals (Dickson, 1965). Facies classification and their

environmental interpretation are based on textural features, fabric, and biota content following Read (1985), Burchette and Wright (1992), Wright and Burchette (1996), and Flugel (2010). The construction of sequence stratigraphy is based on the environmental changes across limiting surfaces, the landward or seaward stepping following Catuneanu (2006), Catuneanu *et al.* (2009), and Catuneanu (2017).

## 4. RESULTS AND DISCUSSION:

### 4.1. Facies Analysis

Ten different carbonate and siliciclastic facies were identified from the Qom Formation in the studied sections. This facies were divided into five facies belts, representing the main depositional paleoenvironments, including delta, tidal inlet, lagoon, shoal, and open marine. The facies have been differentiated based on the sedimentological and paleontological criteria. The general setting is interpreted to be a carbonate ramp system, subdivided into inner, middle, and outer ramp settings following the terminology of Burchette and Wright (1992). Vertical distribution of textures and the identified facies and their relevant paleoenvironment along with sequence stratigraphic architecture of the Qom Formation in the both studied sections are shown in Figure 3.

### 4.2. Deltaic facies (transitional)

#### 4.2.1 F1: Conglomerate

Conglomerate facies at the base of the Qom Formation in both sections have been seen as massive beds. Carbonate cement is predominant between grains in nearly all samples. Particles vary in size from small sand-size to pebble (<64 mm) — silt and tiny sand-size form the matrix. The particles are sandstone, shale, and limestone fragments, which form a poorly to moderate-sorted and mostly subrounded to angular polymictic conglomerate up to 2-5 m thick. This facies has seen heterogeneous mass with reddish in color (Figures 4a and 4b).

Interpretation: The poorly sorted matrix-supported conglomerates which form coarsening-upwards cycles are attributed to the accumulation of clasts in deltaic environments (Martini *et al.*, 2017; Arp *et al.*, 2019). The mostly red color of the matrix shows the oxic condition in time of deposition. Sedimentological characteristics include graded bedding (coarsening upward), the red color of texture, sand to pebble size of particles with angular to semi-rounded clasts, and its

vertical and lateral changes to carbonate facies reveal high-energy water with high bedload in a deltaic environment system. The source of sediments is from nearby highs of Lower Red Formation that surrounded the Qom back-arc basin and have transported to the basin by river channels along with a short distance. The rounding and sorting associated with this conglomerate and the lithology of the conglomerate features will confirm the short distance and the nearby source rock.

#### 4.3. Tidal inlet facies (inner ramp)

##### 4.3.1 F2: *Bioclastic hybrid arenite*

This facies includes bioclastic carbonate up to 20 percent — the bio-clasts consist of echinoid, brachiopod, operculina, and bryozoan. The matrix is made of carbonate mud, which dolomitized in some portions. Monocrystalline and less polycrystalline quartz grains, which are silt to medium sand in size, formed the major detrital particles. This facies consists of a poorly to well sorted with angular to semi-rounded grains (Figures 4c and 4d).

Interpretation: The bioclastic hybrid arenite is a typical facies in mixed carbonate-siliciclastic environments that their framework is made of detrital clasts. The 'arenite' term suggested for rocks consisting of more than 50 percent detrital clasts that accompanied by carbonate clasts (Zuffa, 1985). Deposition of such facies took place in an attached onshore carbonate platform setting with remarkable nearby high topography that transported a large volume of siliciclastic material into the basin (Friedman and Sanders, 1978; Flugel, 2010; Sengupta, 2017). According to sedimentological characteristics such as open marine bioclasts and stratigraphic position adjacent to carbonate shoal, the depositional setting could be tidal inlet that connected the continental area to the ocean and also channels that transported siliciclastic material from delta to the open marine. The large volume of siliciclastic material confirms the deposition of this facies in a short distance to the source rock and as channels connecting the open marine to the shoreline (Flugel, 2010). The channels are maintained by tidal flow; the presence of open marine biota with siliciclastic material confirms this statement.

#### 4.4. Lagoonal facies (inner ramp)

##### 4.4.1 F3: *Bioclast miliolid packstone*

Despite the packstone fabric, the biotic

variations are low, and the constituents include different species of Miliolidae such as *Quinqueloculina* sp., *Pyrgo* sp., *Triloculina* sp., and *Miliola* sp. echinoid, red algae, bryozoan, and bivalve forms the minor features by <10%. Silt size quartz grains are present by 2-5%. This facies shows medium sorting and rounding and only seen in the Kordijan section (Figure 5a).

Interpretation: Miliolid is predominant in a restricted lagoonal environment (Geel, 2000). Recently, most of the porcelaneous benthic foraminifera live in shallow tropical and sub-tropical environments (Lee, 1990; BouDagher-Fadel, 2008; Benedetti and Frezza, 2016). Thus, this facies deposited in a nearly restricted lagoonal setting above the fair-weather wave base (FWWB). The restricted condition can be confirmed by a low distribution of normal marine biota, low variation of foraminifera, and the predominance of porcelaneous foraminifera. The predominance of porcelaneous foraminifera has also revealed waters with high salinity (Read, 1985; Flugel, 2010).

#### 4.5. Bioclastic shoal (inner ramp)

##### 4.5.1 F4: *Bioclast, red algae rudstone/grainstone*

Sparry calcite cement, including blocky and poikilotopic cement, formed the texture. The major biotic constituents are red algal species such as *Lithophyllum* sp. and *Lithothamnium* sp. with 20-30% in abundance and larger than 2 mm in size. Other major biota include echinoid with overgrowth cement, rotalia, bryozoan, and large fragments of bivalves. Gastropod, miliolid, brachiopod spin, and unknown fragments of hyaline benthic foraminifera form the minor biota. Silt, and small and medium-size quartz grains with 5-7% in abundance form the siliciclastic features. All the features in a sparry texture show medium to good sorting and low to medium roundness (Figure 5b).

Interpretation: According to the abundance and large size of the red algae, it seems that these biota have been deposited in the nearest place to their habitat. The best condition for red algae growth is an environment with high nutrition, sufficient oxygen, the wave energy to provide these materials, and a depth of water where appropriate light can penetrate (Bassi, 2005; Halfar and Mutti, 2005). Textural characteristics, including the absence of micrite, sparry cement between the constituent along with specific sorting and rounding, reveal an environment with medium to high wave energy. Thus, based on the biota and sedimentological characteristics, this facies is

deposited in a bioclastic shoal setting above FWFB in the inner ramp.

#### 4.6. Open marine facies (middle ramp)

##### 4.6.1 F5: *Echinoid, bryozoan, red algal packstone/rudstone*

This texture has mainly seen as packstone and occasionally with large size red algae bearing biotic constituents as rudstone. The major biota with 30-40% in abundance are bryozoan (0.5-2 mm in size) and *Lithophyllum* sp. and *Lithothamnium* sp. (both 5 mm to larger than 10 mm in size). Miliolid is present with 3-5% in abundance. The minor biota consists of gastropod, rotalia, brachiopod, and worm tubes. Small to medium sand-size quartz grains are present with 5-10% in abundance. The texture has partly dolomitized or filled by sparry calcite cement (Figure 5c).

Interpretation: high abundance and large size of red algae, partly presence of sparry calcite cement between biota, and the presence of dispersed fragments of benthic foraminifera and rotalia can confirm its proximity to the reef assemblages of the bioclastic carbonate shoal. The predominance of carbonate mud in texture along with oligo-photoc biota such as miliolid, and the predominance of photic dependent biota such as red algal species that is also able to grow and develop in oligo-photoc condition indicating the shallowest open marine facies adjacent to carbonate shoal, with high to medium wave energy (Halfar and Mutti, 2005; Barattolo *et al.*, 2007; Brandano *et al.*, 2009). Thus, this facies based on the presence of photic dependent and independent biota is deposited in waters with normal salinity below FWFB in the middle ramp and adjacent to carbonate shoal.

##### 4.6.2 F6: *Bioclast, nummulitids, operculina wackestone*

The major biotic constituents consist of operculina and nummulites. Echinoid, red algae, brachiopods, bryozoan, and occasionally rotalia form the minor biota in this facies carbonate micrite dolomitized in some parts of the texture. The frequency of quartz grains are 20-30% and vary in size from fine to medium sand (Figure 5d). Interpretation: The predominance of larger benthic foraminifera with a low diameter-thickness (D/T) ratio shows relatively shallow parts of open marine with oligophotic conditions (Geel 2000; Bassi *et al.* 2007). Also, light penetration decrease in the depositional environment reveals by stretched forms of larger benthic foraminifera with low

diameter-thickness (D/T) ratio (Nebelsick *et al.*, 2005; Bassi *et al.* 2007; Khatibi-Mehr and Adabi 2014). Thus, larger benthic foraminifera as the major biota along with echinoid and bryozoan in carbonate mud texture can demonstrate medium to low energy open marine environment between fair-weather wave base (FWFB) and storm wave base (SWB) in the middle ramp (Flügel 2010; Adabi *et al.*, 2016).

##### 4.6.3 F7: *Red algae, bryozoan, brachiopod packstone/rudstone*

The main biotic constituents are brachiopod, bryozoan, and some echinoid fragments. Red algal fragments show low frequency. Rotalia and miliolid forms minor biota. Small to medium sand-size quartz grains with 5-10% in abundance are dispersed within the matrix. Dolomitization occurred in some parts of the micritic matrix (Figure 5e).

Interpretation: Bryozoan assemblages are common in calm and low energy waters of shallow open marine. Although they are photic independent heterotroph organisms and found independently of water depth (Pomar, 2001; Drinia *et al.*, 2009), nonetheless, the presence of red algae as the main biota with high frequency reveals shallow parts of open marine. A high abundance of red algal fragments defines waters with sufficient light and relatively high energy in front of carbonate shoal (Pomar, 2001). In this facies, the biotic constituents suggest calm and low to relatively medium energy waters with normal salinity. The medium sand-size of red algal fragments and their medium roundness can be indicative of much more movement with greater distance (Perrin, 1995; Brandano *et al.*, 2009). Thus, based on all textural and biotic pieces of evidence, this facies was deposited in low energy open marine setting in middle ramp above SWB.

##### 4.6.4 F8: *Echinoid, bryozoan, brachiopod wackestone/floatstone*

This texture reveals as wackestone but in a few samples contain bryozoan and brachiopod, larger than 2 mm and even centimeter in size that are floating in a mud matrix reveal as floatstone. The major biota are echinoid, bryozoan, and brachiopod. Small benthic foraminifera such as miliolid is rarely present. Ostracod and unknown micritized biota (peloid) has also present. The frequency of quartz grains is 1-5%, which varies in size from small to coarse sand (Figure 5f).

Interpretation: Echinoid as the main biota has been deposited in relatively deep waters of

open marine in the middle ramp (Barattolo *et al.*, 2007). All the main biota in these facies including bryozoan and brachiopod are photic independent biota and can deposit in relatively deeper parts of open marine settings. Furthermore, these biota are stenohaline and indicators of waters with normal salinity (Holcová and Zágöršek, 2008; Drinia *et al.*, 2009). The low variety and well-preserved coarse grain biotic features, along with the predominance of carbonate mud suggest a low energy depositional environment. The main biotic constituents such as brachiopod, bryozoan, and echinoid with low biotic abundances suggest lower parts of the middle ramp, adjacent and above SWB with limited water circulation.

#### 4.7. Open marine facies (outer ramp)

##### 4.7.1 F9: Sandy mudstone

This facies mainly consists of carbonate mud deposits. Silt and small sand-size quartz grains are scattered through the matrix with a 10-20% frequency. Glauconite is observed with minor amounts. Unknown shell fragments have also been present. This facies in hand specimen is dark cream to light gray. Pyritization occurred in the matrix (Figure 5g).

Interpretation: During a sea-level rising or subsidence in a sedimentary basin, carbonate deposits are drowned, and deep water limy mud is dominant (Tucker and Wright, 2009). All evidence including the presence of glauconite, pyritization, and dark color of this facies in both microscopically and hand specimen suggest that deposition took place in low energy and anoxic waters of open marine in an outer ramp setting below SWB.

##### 4.7.2 F10: Shaly mudstone

Shaly mudstone facies includes the marl lithology interval of the Qom Formation in the Kordijan section. The rocks showing these facies are microscopically light gray, and in hand specimen is gray. Silt size quartz grains are scattered within the matrix in a minor amount. Shaly mudstone facies are completely homogenous, and no biota or shell fragments have been observed (Figure 5h).

Interpretation: During the sea-level rise, mudstone and shale can be formed in deep waters of open marine settings. The lime and clay that formed the shaly mudstone occur as suspended and will precipitate in a low energy marine environment. Thus, according to their stratigraphic position, which is taking place above open marine

limestone strata, they have deposited in a low energy condition below SWB in an outer ramp setting. This facies belongs to relatively deep waters with no biotic fragments, and due to its distance from land and the source area, there are no siliciclastic materials.

The description and characteristics of the identified sedimentary facies, as well as facies associations and some of their main features recognized within the studied sections, are summarized in Table 1.

#### 4.8. Sedimentary Environment

Due to the specific characteristics of the Qom Basin and its widespread in microplate of Central Iran along with high facies variation, thickness, and back-arc geometry, a distinct sedimentary model for different parts of Iran, is impossible. Based on sedimentological and biological data in surface and subsurface sections, different sedimentary models are suggested for deposition of the Qom Formation by many researchers, e.g. a homoclinal ramp by Reuter *et al.* (2007), Saddighi *et al.* (2012) and Amirshahkarami and Karavan (2015) in Qom Province and Esfahan-Sirjan region. However, a rimmed shelf by Vaziri-Moghaddam and Torabi (2004), and a non-rimmed shelf by Mohamadi *et al.* (2011) have also been proposed.

The factors controlling the rate and type of carbonate production are nutrient, light, temperature, salinity, water depth, and chemistry. These factors, along with geological setting, control the carbonate platform geometry and determine the grain type, grain distribution, and the rate of carbonate factory (Brandano *et al.*, 2009).

Facies analysis based on lithology, sedimentary structures, texture, and biotic and abiotic features from the studied sections of the Qom Formation led to the recognition of ten facies deposited in five subenvironments, including delta, a tidal inlet, lagoon, shoal, and open marine. Palaeoenvironmental reconstruction based on the identified facies suggests a homoclinal carbonate ramp for the Qom Formation in the studied area (Figure 6). This suggestion is supported by some evidence including the absence of continuous and large barrier reefs, gradual variation in facies from delta to shallow open marine, the absence of calciturbidites, and slump and slide structures, and lack of oncoid, pisoid and aggregate grains that are mostly present in rimmed carbonate shelf environments. Burchette and Wright (1992) divided a carbonate ramp into an inner ramp

(above FWWB), middle ramp (between FWWB and SWB), and outer ramp (below SWB). Sedimentary facies in the Qom Formation mainly occurs in the middle ramp setting.

The inner ramp includes delta, tidal flat, lagoon, and shoal facies respectively recognized by occurrence of coarsening upward massive polymictic conglomerate (F1, delta), bioclastic hybrid arenite including high sand and open marine biota (F2, tidal flat), porcelaneous foraminifera in a carbonate mud matrix (F3, lagoon), and abundance of red algae accompanied by open marine biota and siliciclastic sediments in a sparry texture (F4, shoal).

The middle ramp consists of four facies from proximal (adjacent to shoal) to distal (adjacent to SWB) part. The middle ramp in the proximal part is characterized by larger benthic foraminifera (e.g. operculum and nummulitids), and shoal derived bioclasts such as red algae in a packstone and rudstone texture (F5-6). The distal parts of the middle ramp include mainly photic independent heterotroph and stenohaline organisms (such as bryozoan and echinoids) that are indicators of normal salinity waters of open marine (Drinia *et al.*, 2009).

The outer ramp is characterized by sandy and shaly mudstone with pyritization in the matrix that is evidence of relatively deep waters with anoxic condition and small unknown shell fragments and glauconite (F9-10).

#### 4.9. Sequence Stratigraphy

A stratigraphic sequence model defines depositional sequences as genetically related chronostratigraphic units that are representative of a single cycle of relative sea-level rise and fall, bounded by unconformity surfaces (e.g. Posamentier and Vail, 1988; Van Wagoner *et al.*, 1990; Posamentier and James 1993; Catuneanu *et al.*, 2006). Retrogradational, aggradational, and progradational stacking patterns in the framework of a depositional sequence are developed due to eustatic sea-level fluctuations.

The stratigraphic sequence interpretation that is proposed for the Qom Formation is based on age, field description, and the broad paleoenvironmental inferences revealed by facies analysis and stacking patterns of facies (Figure 3). In the carbonate platform of the Qom Formation with predominant of warm climate, which is Early Miocene (Aquitania) in age, the sequence boundaries are characterized by siliciclastic facies

(delta and tidal inlet). The depositional sequences consist of three systems tracts, including lowstand system tract (LST), transgressive system tract (TST), and highstand system tract (HST). Each sequence comprises complex facies of subtidal, including lagoon, shoal, and open marine, which covered by siliciclastic facies. The maximum flooding surface (F9-10) is characterized by water deepening and the maximum transgressive in seawater, which is defined by outer ramp facies association. Vertical facies variations and identified environments connected with relative sea-level changes led to the identification of two third-order depositional sequences in the Qom Formation (Figure 3).

##### 4.9.1 Depositional sequence 1 (DS1)

The depositional sequence 1 with the age of Aquitania is 70.75m and 58.07m thick, respectively, in Kordijan and Ashtian sections. The DS1 is divided into LST, TST, and HST. The delta massive conglomerate beds of F1, which is a transitional environment, formed the basal part of DS1. The enormous conglomerate in both sections is deposited over the sandstone beds of the Oligocene Lower Red Formation (Figure 3). The basal deltaic conglomerate with a coarsening upward sequence has been deposited during the period of falling sea level as an LST. The overlying carbonate rocks with shoal and middle ramp facies association of F4 (shoal), F5, F7, and F8 (all open marine: middle ramp) have been deposited during the period of sea-level rise and are interpreted as transgressive system tract (TST) with retrogradational stacking pattern. The TST is characterized by packstone, grainstone, rudstone, and floatstone textures with normal waters biota such as rotalia, red algae, bryozoan, and Echinoidea. The photic independent of open marine biota reveals a rise in sea level that reaches the maximum, equivalent to the maximum flooding surface (MFS). The sandy and shaly mudstone of the F9 and F10 with glauconite and shell fragments and pyritization in matrix characterize the MFS. The main packstone and rudstone textures of the lagoon (F3), shoal (F4), and open marine (proximal middle ramp facies association: F5-6) with mainly aggradational and a few progradational stacking pattern that overlies the MFS characterize the HST. The upper part of the HST is characterized by bioclast hybrid arenite (F2) in both sections and indicate the tidal inlet environment and a type 2 sequence boundary (SB2).

##### 4.9.2 Depositional sequence 2 (DS2)

The depositional sequence 2 is 23.75m thick in the Kordijan section and 43.92m thick in the Ashtian section with the age of Aquitanian. The DS2 can be subdivided into TST and HST (Figure 3). The carbonate rocks of middle ramp facies association (F5-7) with retrogradational stacking patterns are formed during a period of sea-level rise and are interpreted as transgressive deposits of TST (Figure 3). The facies of TST (F5-7) consist of larger benthic foraminifera such as Nummulitidae and Operculina as well as red algae, brachiopod and bryozoan. Large fragments of bryozoan and brachiopod along with Nummulitidae and broad and flat operculina, larger than 2mm in size with rudstone texture, are terminated in outer ramp facies association (F9-10) with evidence of low energy and anoxic condition of relatively deep waters. These facies indicate a maximum increase in sea-level changes, equivalent to the MFS. The mostly packstone and rudstone textures of shoal and proximal middle ramp facies association with dominant of benthic foraminifera (e.g. rotalia) and red algae are overlain by the MFS. These sediments are interpreted as deposition of the HST with a progradational stacking pattern (Figure 3). The upper part of the HST is characterized by bioclast hybrid arenite (F2: tidal inlet) in the Ashtian section and bioclast, red algae rudstone/grainstone (F4: shoal) in the Kordijan section indicating tidal inlet and shoal environments. The Upper Red Formation of Miocene age overlies the DS2 in both sections. There is a type 1 sequence boundary (SB1) between the Qom Formation and the Upper Red Formation.

#### 4.10. Correlation of Depositional Sequences

Precipitation of carbonate sediments is influenced by subsidence and sedimentation rate that are related to the tectonic evolution of the belts that surrounded the Qom back-arc basin. The Oligocene-Miocene sedimentary rocks of the Qom Formation in microplate of Central Iran have some similarities with the Oligocene-Miocene sedimentary deposits of the Asmari Formation in the Zagros Basin and the equivalent formations in the Arabian Plate. For instance, the biotic constituents are the same, and the sedimentary paleoenvironments are a homoclinal ramp system; however, according to the geological setting these basins have not been connected during the Early Miocene. Sharland *et al.* (2001, 2004) and Simmons *et al.* (2007) in Arabian Plate have defined a set of regional maximum flooding surfaces (MFS). They have used MFS for

subdividing the sedimentary succession of the Arabian Plate into a series of synchronous packages. These packages, which are genetic stratigraphic sequences (Galloway, 1989) took place within a set of Tectonostratigraphic Megasequences (TMS) that subdivide the geological history of the Arabian Plate from Precambrian to the Present. These TMS are defined as the package of sediments lying between the unconformity marking both the onset of Red Sea Rifting and the first continental collision between Arabia and Eurasia and the present-day topographic surface. The Qom Formation with the age of Oligocene–Miocene sits within the latest of the TMS (AP11), which is defined as sedimentary packages that took place between two signs of unconformity (Sharland *et al.*, 2001, 2004). The correlative sequence boundaries between Sharland *et al.* (2001, 2004), Simmons *et al.* (2007) and this study with increasing age are as following (Figure 7):

1. The Ng20 SB is equal to the type 1 SB at the top of DS2.
2. The Ng10 SB is equal to type 1 SB at the base of DS1.

The previous sequence stratigraphic studies on Oligo-Miocene deposits of the Zagros Basin include Ehrenberg *et al.* (2007) and Van Buchem *et al.* (2010). In their studies of the Oligo-Miocene Asmari Formation in Dezful Embayment and Izeh zone located in the southwest of Iran defined seven sequence surfaces that were dated and correlated between several outcrops and sub-surfaces wells. Among these sequence surfaces with the Early Miocene (Aquitanian) age of the Qom Formation three sequence boundaries are correlative with those of Ehrenberg *et al.* (2007) and Van Buchem *et al.* (2010). With increasing age, these surfaces are as following:

1. Bu20 SB and SB VI is equal to the type 1 SB at the top of DS2.
2. Aq20/Bu10 and SB V is equal to the type 2 SB between DS1 and DS2.
3. Aq10 and SB IV is equal to the type 1 SB at the base of DS1.

In this study, three recognized sequence boundaries are well-matched with the sequence boundaries that are proposed by Ehrenberg *et al.* (2007) and Van Buchem *et al.* (2010) (Figure 7).

## 5. CONCLUSIONS:

Based on field observations, textural analysis, and biotic constituents, ten facies have

been identified. The Early Miocene (Aquitania) Qom Formation in the Qom back-arc basin in the microplate of Central Iran has been deposited in a homoclinal ramp setting including delta, a tidal inlet, lagoon, shoal, and open marine subenvironments. The absence of continuous large barrier reefs, pisolite, oncolite, slump structures, and calciturbidites support this suggestion. The Qom Formation in studied sections mainly occurs in an open marine setting. Furthermore, based on sequence stratigraphic studies, two third-order depositional sequences in the Aquitania of the Qom Formation have been recognized. Based on the chronostratigraphic sequence correlation, these depositional sequences have a good correlative architecture with Arabian Plate sedimentary successions and the sequences that have been recognized for the Oligocene-Miocene Asmari Formation in Dezful Embayment and Izeh zone in the southwest of Iran by other researchers.

## RESUMO

A causa do câncer em pacientes permanece um mistério. Várias teorias e suposições não dão confiança na compreensão do processo de câncer. Até que a etiologia do câncer seja estudada, não poderemos avançar apesar do desenvolvimento de tecnologias farmacêuticas e tratamentos inovadores. Para resolver esse problema, pretende-se usar todos os dados relacionados ao desenvolvimento do câncer, mesmo que eles não tenham um vínculo óbvio com a doença. Mesmo quando uma célula cancerígena aparece e começa a criar seu pool de células cancerígenas alteradas, não sabemos. Os médicos diagnosticam o câncer quando o tumor atinge certos tamanhos e afeta a função do órgão. O número de células cancerígenas aumenta muito rapidamente. Os fatores que aceleram essa reprodução das células cancerígenas são muitos, o que significa que ainda não vemos a verdadeira causa. A célula cancerígena mantém os recursos da célula original em graus variados, da semelhança pronunciada à perda quase completa de propriedades celulares saudáveis. Quanto mais a célula estranha é alterada, mais rápido ela cresce e o prognóstico para o paciente se deteriora. O mais preocupante é que a incidência de câncer está aumentando, o que significa que a causa não foi encontrada. As mortes por câncer continuam altas. Este artigo discute o caso de um paciente com um membro amputado por câncer (câncer de pele do pé). Durante um estudo de 10 anos da medula óssea do fêmur, pela primeira vez, a medula óssea foi obtida do fêmur de um paciente com câncer. As descobertas podem ajudar pesquisadores e médicos a entender melhor o processo do câncer e a encarar o problema de maneira diferente.

**Palavras-chave:** *medula óssea femoral, células-tronco, células-tronco hematopoiéticas, câncer de pele.*

## ABSTRACT

The cause of cancer in patients remains a mystery. Various theories and assumptions do not give confidence in understanding the cancer process. Until the etiology of cancer is studied, we will not be able to move forward despite the development of pharmaceutical technologies and innovative treatments. To solve this problem, it is intended to use all data related to cancer development, even if they have no obvious link to the disease. Even when a cancer cell appears and starts creating its pool of altered cancer cells we don't know. Doctors diagnose cancer, when the tumor reaches certain sizes and disorders the function of the organ. The number of cancer cells increases very quickly. The factors that accelerate this reproduction of cancer cells are many, which means that we still do not see the true cause. The cancer cell retains the features of the original cell to varying degrees from pronounced similarity to almost complete loss of healthy cell properties. The more the foreign cell is altered, the faster it grows and the prognosis for the patient is deteriorated. The most worrying thing is that the incidence of cancer is increasing, which means the cause is not found. Cancer deaths remain high. This article discusses the case of a patient having a limb amputated for cancer (foot skin cancer). During a 10-year study of bone marrow from the femur, for the first time, bone marrow was obtained from the femur of a patient with cancer. The findings could help researchers and doctors better understand the cancer process and look at the problem differently.

**Keywords:** *femoral bone marrow, stem cells, hematopoietic stem cells, skin cancer.*

## АННОТАЦИЯ

Причина возникновения рака у больных остается загадкой. Различные теории и предположения не

дают уверенности в понимании онкологического процесса. До тех пор, пока этиология рака не будет изучена, мы не сможем двигаться вперед, несмотря на развитие фармацевтических технологий и инновационных методов лечения. Для решения этой проблемы предполагается использовать все данные, связанные с развитием рака, даже если они не имеют очевидной связи с болезнью. Даже когда появляется раковая клетка и начинает создавать свой пул измененных раковых клеток, мы этого не знаем. Врачи диагностируют рак, когда опухоль достигает определенных размеров и нарушается функция органа. Количество раковых клеток увеличивается очень быстро. Факторов, ускоряющих такое размножение раковых клеток, очень много, а это значит, что мы до сих пор не видим истинной причины. Раковая клетка сохраняет черты исходной клетки в разной степени - от ярко выраженного сходства до почти полной потери свойств здоровой клетки. Чем больше чужеродная клетка изменяется, тем быстрее она растет и прогноз для пациента ухудшается. Самое тревожное заключается в том, что заболеваемость раком растет, а значит, причина не найдена. Смертность от рака остается высокой. В данной статье рассматривается случай пациента, которому ампутировали конечность по поводу рака (рак кожи стопы). Во время 10-летнего исследования костного мозга из бедренной кости впервые был получен костный мозг из бедренной кости больного раком. Полученные результаты могут помочь исследователям и врачам лучше понять процесс развития рака и взглянуть на проблему по-другому.

**Ключевые слова:** *костный мозг трубчатых костей, стволовые клетки, гемопоэтические стволовые клетки, рак кожи.*

## 1. INTRODUCTION:

Worldwide, the number of cancer patients is increasing. In overwhelming numbers, these are older people, regardless of gender. The importance of determining the cause of cancer and the overall understanding of the pathogenesis of the process is understood by doctors in all countries. But there is no consensus, most hold the hypothesis of immune system disruption, which stops determining cells are necessary for removal (Weaver, *et al.*, 2008).

The assumption of the cause of the cancer process as a result of the incorrect protective work of the immune system does not explain the whole variety of cancer transformations. The cancer process is based on two important details, cell growth, which can be different and loss of differentiation, the degree of which can differ greatly from the healthy cell of this tissue. In recent years, we have studied the cellular mechanisms of cancer development, the discovery of oncogenes and antioncogenes. So far, this is of interest, but will this data make a difference? By influencing the work of anti-oncogenes, the fight against cancer can be improved, but the problem remains problem (Hernández, 2015).

The most important thing is to understand the function and features of the cancer cell, without fine study of this cell there is no point in looking for a drug for treatment. For now, we're still losing cancer in the fight. In surgical practice, they are periodically forced to amputate the lower limb because it is impossible to preserve it (Nikolaeva *et al.*, 2017). High amputations lead to limited social adaptation of patients (Nikolaeva *et al.*, 2015), significantly reduce the life expectancy of

patients as a result of damage to the contralateral limb and the addition of various complications (Sisla *et al.*, 2011).

The lower limb that is removed during a forced amputation is an important bone marrow depot, where about 25% of the patient's total bone marrow is located in the femoral cavity. Currently, it is proved that the restoration of a damaged organ occurs not only due to the activation of organ regional stem cells, but also due to migration to the zone of damage of MMSCs from other organs, and primarily from the bone marrow (Nikolaeva 2015; Bruder *et al.*, 1994; Gu *et al.*, 2008).

The immediate goal of biomedical research in this area is to use innovative cell technologies (Paladino *et al.*, 2008; Weaver *et al.*, 2008; Krause, *et al.*, 2002). Most of the known technologies for taking bone marrow from living individuals for subsequent bone marrow transplantation (Nolan *et al.*, 2010; Zielins *et al.*, 2016; Rothrauff *et al.*, 2013). use of an isolated stem cell concentrate involves the use of invasive trepanobiopsy techniques (Vos *et al.*, 2006; Jamshidi *et al.*, 1971; Lu *et al.*, 2011). For the first time, mesenchymal stem cells were found in the bone marrow (Norgren *et al.*, 2007; Onodera *et al.*, 2010), but all bone marrow studies were conducted on the bone marrow of flat bones – the red bone marrow (sternal puncture or iliac crest (Hernández 2015; Eagle *et al.*, 2018; Wei *et al.*, 2013). Studies of the bone marrow of tubular bones were not performed due to the impossibility of obtaining it in vivo.

This study aimed a quantitative analysis of multipotent mesenchymal stromal (MMSC) and hematopoietic stem cells (HSCs) in bone marrow samples of amputated limbs in a patient with skin

cancer of the limb.

## 2. MATERIALS AND METHODS:

### 2.1. Characteristics of the patient

This case is presented by one patient who had a lower limb amputation after signing informed consent. The indication for amputation was: a trophic ulcer of the limb with signs of malignancy. Obtaining bone marrow samples: The test bone marrow sample was obtained in the operating room immediately after the amputation of the lower limb. Bone marrow was extracted from the lumen of the femur with a Volkmann spoon into a sterile test tube, which was transported to the laboratory.

The bone marrow was subjected to soft homogenization with the addition of a phosphate-salt buffer. The removal of adipose tissue was carried out by 10 minutes of settling the sample, while the fat of the bone marrow rises to the upper layer. Without affecting the upper layer, the lower phase of nucleated bone marrow cells was taken into a new tube and washed twice in a phosphate buffer, followed by centrifugation at 400g for 5 minutes. The cell sediment was resuspended in 300 µl of phosphate buffer, and their number was calculated in the Goryaev chamber. The cell suspension was diluted with a phosphate buffer to a concentration of 107 cells/ml.

### 2.2. Immunophenotyping of HSCs and MMSCs

The study of the HSC and MMSC phenotype was performed by flow cytometry using direct immunofluorescence. We used ready-made monoclonal antibodies from B.D. Biosciences (Becton Dickinson, USA) labeled with FITC (fluorescein isothiocyanate), P.E. or RD1 (phycoerythrin), PC5, 5 (phycoerythrin-cyanin 5.5), PC7 (phycoerythrin-cyanin 7), and APC (allophycocyanin). The cd90-PE/CD45-PC5,5/CD45RA-PC5,5/CD34-PC7/CD38-APC panel was used for phenotyping HSCs. The human MSC Analysis Kit (Becton Dickinson, USA) containing the CD90-FITC/CD45-PE/CD34-PE/CD11b-PE/CD19-PE/HLA-DR-PE/CD105-PC5, 5/CD73-APC panel was used for phenotyping MMSCs. The distribution of antibodies along the fluorescence channels was carried out in accordance with the principles of panel formation for multicolored cytofluorimetric studies (*Kudryavtsev et al., 2015*). Sample preparation was performed using the standard method (*Sutherland et al., 2018*). At least 50,000 cells were analyzed in each sample.

A total of 5 µl of antibodies were added to

a 50 µl bone marrow sample, incubated in the dark for 15 min., 500 µl of BD FACS Solution 1X (Becton Dickinson) lysing solution was added, incubated for 10 min. in the dark, then centrifuged at 1500 rpm for 5 min., the supernatant was drained, the precipitate was washed three times with BD FACS Flow (Becton Dickinson) solution, followed by centrifugation at 1500 rpm for 5 min. 300 µl of BD FACS flow solution was diluted and analyzed using a flow cytometer BD FACSCantoII (Becton Dickinson). For immunophenotyping, HSCs used antibodies to surface antigens of human cells on the recommendation of the manufacturer B.D. Biosciences (Becton Dickinson) PE-Cy7 CD34, PE CD90 and a mixture of negative control antibodies (APC CD38, PerCP-Su5. 5 CD45 and PerCP-Su5. 5 CD45RA). Immunophenotyping of MMSCs was performed using the Human MSC Analysis Kit (Becton Dickinson), which contains conjugated antibodies to MMSC markers (FITC CD90, PerCP-Su5.5 CD105, and APC CD73), and a mixture of negative control antibodies (PE CD45, PE CD34, PE CD11b, PE CD19, and PE HLA-DR).

### 2.3. Characteristics of the used markers

CD11b is non-covalently associated with  $\beta 2$  integrin and is expressed on granulocytes, macrophages, dendritic cells, N.K. cells, and subsets of T and B cells. CD11b It participates in the transfusion of cells such as neutrophils and monocytes, increases the activity of neutrophils, causes granulocyte adhesion, increases the activity of neutrophils (<https://www.biolegend.com/en-us/products/fic-anti-human-cd11b-antibody-8299>).

CD19 is part of the superfamily of immunoglobulins expressed on B cells and follicular dendritic cells. CD19 is involved in the development, activation, and differentiation of B cells. CD34 is a monomeric sialomucin-like type I glycoprophosphoprotein, selectively expressed on most hematopoietic stem/progenitor cells, bone marrow stromal cells, capillary endothelial cells, embryonic fibroblasts, and some nerve tissues. CD34 mediates cell adhesion of lymphocytes by binding to L-selectin and E-selectin ligands.

CD38 is expressed on early hematopoietic progenitors and white blood cells, liver stellate cells, astrocytes, and epithelial cells. CD38 expression can be increased when cells are activated. CD38 catalyzes the production of ADP cyclic ribose. CD38 induces proinflammatory cytokine production and proliferation.

CD90, also known as Thy-1, a member of

the immunoglobulin superfamily, interacts with CD45 during signal transduction during lymphocyte proliferation and differentiation. CD90 is expressed on hematopoietic stem cells, neurons, thymocytes, peripheral T cells, fibroblasts, and stromal cells (Alexa Fluor®). CD45, a panleukocytic marker represented by a single-stranded I-type membrane glycoprotein. CD45 is a signaling molecule that regulates various cellular processes, including cell growth, differentiation, cell cycle, and oncogenic transformation.

CD45RA, a marker of young cells, a variant of the 4-exon compound of CD45 tyrosine phosphatase. The CD45RA isoform is expressed on resting T cells, medullary thymocytes, B cells, and monocytes. CD73 is expressed on mesenchymal stem cells, T and B cells and their derivatives (<https://www.biolegend.com/en-us/products/pe-anti-human-cd73-ecto-5-nucleotidase-antibody-6092>). CD73 performs t-cell costimulation and mediates lymphocyte adhesion to follicular dendritic cells and endothelial cells.

CD105, an integral membrane homodimeric type I protein found on vascular endothelial cells and placental syncytiotrophoblasts. CD105 is not expressed on fibroblasts, but is detected on macrophages and monocytes (<https://www.biolegend.com/en-us/products/pe-anti-human-cd105-antibody-3711>). CD105 expression is increased on activated endothelium in tissues undergoing angiogenesis, such as tumors, or in cases of wound healing or skin inflammation.

HLA-DR, a marker of activated cells, an antigen of the main histocompatibility complex of class II, is expressed on B cells, activated T cells, monocytes/macrophages, dendritic cells, and other non-professional antigen-presenting cells

### 3. RESULTS AND DISCUSSIONS:

It is known that the amount of bone marrow obtained depends on the level of amputation (Nikolaeva, 2015). The level of amputation in this study was determined individually. The volume of extracted bone marrow was determined by the level of amputation (upper, lower, or middle third of the thigh) and was equal from 10 to 100 ml the largest amount of bone marrow (up to 100 ml) was obtained when the limb was amputated at the level of the upper third of the thigh. Bone marrow is a ready-made drug with many important effects (Zielins *et al.*, 2016; Rothrauff and Tuan, 2013). In this case, the patient was amputated at the level

of the middle third of the thigh. The number of cells in the bone marrow depended on the amount of bone marrow obtained and was approximately 500 thousand to 3 million cells per sample.

On average, the content of MMSC and HSC in the bone marrow of amputated limbs is the same, with a small predominance of the number of MMSCs. This patient was diagnosed with skin cancer of the lower leg, MMSCs were completely absent, it was the only bone marrow that did not have mesenchymal stem cells.

Malignant neoplasms have their own stem tumor cells. This is a small subpopulation of the least specialized cancer cells that have the ability to self-renew and give rise to all cell populations present in the original tumor, including initiating neoangiogenesis and growth of the tumor stroma. In all normal organs and tissues, there are stem cells that are responsible for self-renewal-physiological or reparative regeneration, as well as more specialized and Mature cells that perform the main functions of the organ or tissue. The same is true for tumors. That is, the tumor resembles an organ in structure and, of course, should not differ from the General principle of building biological structures.

It should be noted that for a long time, there was a question of how much cancer stem cells are similar to normal stem cells. And which type of stem cells first begins to change in malignant neoplasm. It was assumed that the tumor begins with changes in completely undifferentiated stem cells, giving rise to all other cells capable of almost unlimited self-renewal. Cancer stem cells in leukemia, these important cells-self-replicating beginnings of tumors do not originate from undifferentiated stem cells, but from their offspring-partially committed non-self-renewing progenitor cells (short-lived cells that can give rise to several, but not all, types of blood cells).

The genetic program of fully developed leukemic stem cells is not the same as that of normal stem cells. This is a very important discovery, which is likely to be typical for most other types of tumors because the most important properties of stem cells are resistance to damaging factors and rare division. These properties do not allow stem cells to accumulate the mass of genetic changes that are necessary for the transformation of a normal cell into a cancer cell. But progenitor cells, on the contrary, actively proliferate, but less plastic than stem cells. They are committed, and the ways of their further development are predetermined by gene expression and limited. In the study of the femoral bone marrow, hematopoietic and mesenchymal

stem cells were determined in the resulting bone marrow. Usually, the number of cells did not exceed 3 million. In this patient with skin cancer, the total number of cells was 75 million, which is much higher than the cell content in comparison with other amputations (25 times). In addition to the absence of MMSCs, this patient had a higher hematopoietic stem cell content than other amputations of 0.025%.

The cause of cancer is not yet clear, and this is a big problem. There are many theories, each representing some aspect and revealing the mystery of the curtain of the origin of the disease. But there are also those who contradict each other, and the general answer to the question—where does cancer come from? "not yet. At the present stage, the immune theory prevails, because the immune system is being suppressed, it is the immune system that first begins to fight mutated cells and destroys them in the first stages.

The etiology is based on several factors: there is an influence both external and internal, on genes during cell division and during normal life. As a result, the cells' genetics break down, and they mutate, turning into cancer cells. After that, such tissues begin to divide and grow endlessly, absorbing, and damaging the nearest organs. The so-called oncogenes were found — these are genes that, under certain conditions and external factors, begin to regenerate any cell in the body into a cancer cell. Until this state, these genes are dormant. That is, a gene is that part of the program code in the body that begins to work only at a certain moment and under certain conditions. That is why the risk of getting sick in people whose parents had cancer is higher than in others. But we must remember that all mutated or damaged cells are fought by our immune system, which constantly scans the body for damage and destroys dangerous cells. If the immune system is lowered, the chance of getting sick in this case is greater.

Today, this theory is the main and most common, which is used by almost all oncologists and scientists. Since all other theories are mostly just a risk factor, whether it's viruses or hepatogenic, it has been observed that most oncocytes occur in an acidic environment. In such an environment, the immune system and all nearby tissues of the body are weakened. And if the environment is made alkaline, then everything will be the opposite, and cancer cells will simply not be able to survive in it, and the immune system will be normal. When the environment is acidic, the immune system is greatly reduced, and the body has a favorable environment for the emergence of

cancer cells. Proponents of the immune theory believe that cancer cells constantly occur in the course of life, but the immune system periodically destroys them. With any impact inside the body and during the regeneration process, our cells grow and repair all damage. And the whole process is controlled by the immune system.

But with the constant occurrence of damage and various disorders, mutation may occur, and control may stop. In the laboratory, under any conditions, no doctor or scientist in the world has been able to turn a normal cell into a cancer cell. They were affecting it with both chemical reagents and radiation. No one in the lab was able to initiate metastasis. The DNA of a cancer cell is 70% similar to that of protozoa. Healthy cells cannot turn into cancer, changing by 70%. They can't move around the body and metastasize, forming new tumors.

The basis of the pathogenesis of all neoplasms is the appearance and reproduction of genetically modified tumor cells with special properties in the body. Tumor cells are changed genetically in the sense that they are able to transmit their pathological properties to descendants: when a tumor cell divides, daughter cells are formed, at least some of which retain their tumor properties. This transfer of tumor properties by cells to descendants can occur in an infinite number of generations. In most cases, the division of tumor cells is the main way to grow primary tumor nodes.

Primary nodes of many types of human and animal tumors are clones, i.e., all cells of this node are descendants of one original tumor cell. The tumor tissue also retains specific antigens of the original tissue. Therefore, successful transplantation of tumors to animals of other species (heterotransplantation) is possible only if the recipient's immune responses are weakened or prevented. This can be achieved in several ways:

1. transplanting tumor cells into tissues where immune responses are weakly induced, such as the anterior chamber of the eye or the brain;
2. introducing immunosuppressive drugs to the recipient;
3. using animals with genetic defects in the immune response as recipients.

Against the background of a weakened immune system, human tumors have already been successfully transplanted to animals. The properties of a population of tumor cells can

change during the growth of primary and secondary tumor nodes, as well as during the passivation of the transplanted tumor. These changes seem to be a consequence of the fact that new genetic variants of tumor cells with properties different from those of most cells in the population may appear in the tumor tissue. If these cell variants have any "advantages" over most tumor node cells, then as a result of selection, these cells will accumulate in the tumor tissue.

Persistent irreversible changes in one or more properties of tumor tissues are called tumor progression. The progression of each tumor can be multi-stage: during the development and growth of this tumor, several different variants of tumor cells may consistently prevail in it. Under normal conditions, each subsequent stage of progression increases the difference between the tumor tissue and the original normal tissue. As a result of tumor growth, its individual cells can break off, get into other organs and tissues, and cause the growth of a secondary, daughter tumor there. This process is called metastasis, and the daughter tumor is called metastasis.

Only malignant neoplasms are prone to metastasis. In this case, the structure of metastases usually does not differ from the primary tumor. Very rarely, they have even lower differentiation, and therefore are more malignant. There are three main ways of metastasis: lymphogenic, hematogenic, and implantation.

- a. The lymphogenic pathway of metastasis is the most frequent. Depending on the ratio of metastases to the lymph flow pathway, antegrade and retrograde lymphogenic metastases are isolated.
- b. The hematogenic pathway of metastasis is associated with the entry of tumor cells into the blood capillaries and veins.
- c. The implantation pathway of metastasis is usually associated with the entry of malignant cells into the serous cavity (when all layers of the organ wall germinate) and from there - to neighboring organs. The fate of a malignant cell that has entered the circulatory or lymphatic system, as well as the serous cavity, is not completely predetermined: it can give rise to a daughter tumor, or it can be destroyed by macrophages.

Currently, there are no changes in the clinical and biochemical parameters of blood that are specific for oncological processes. However, recently, tumor markers (O.M.) have become

increasingly important in the diagnosis of malignant tumors. O.M. in most cases are complex proteins with a carbohydrate or lipid component, synthesized in tumor cells in high concentrations. These proteins can be associated with cellular structures and then they are detected in immunohistochemical studies.

A large group of O.M. is secreted by tumor cells and accumulates in the biological fluids of cancer patients. In this case, they can be used for serological diagnostics. The concentration of O.M. (primarily in the blood), to a certain extent, may correlate with the occurrence and dynamics of the malignant process. In recent years, there have been a number of trends in the epidemiological situation of cancer morbidity and mortality: first, there has been an increase in cancer morbidity and mortality in all countries of the world.

For many years, oncological diseases have confidently occupied the 2nd place in the structure of causes of death after cardiovascular pathology. Since there is now a tendency to reduce mortality from the latter, tumors have a clear chance of becoming a leader among the causes of death in the XXI century. Secondly, the increase in the incidence of tumors is registered in all age groups, but the largest number of cancer patients are people older than 50 years. Proto-oncogenes: these are normal cell genes that are usually inactive. Their activation and transformation into oncogenes that encode certain oncoproteins are accompanied by cell proliferation. Normally, this process takes place in embryogenesis, with age-related growth of organs and tissues, and regeneration. Antioncogenes: Genes that have the opposite effect. The most studied antioncogene p53. Pathological activation of oncogenes or suppression of antioncogenes can lead to tumor growth.

#### 4. CONCLUSIONS:

The development of a pathological process of an oncological nature is affected by the state of the bone marrow. Perhaps this is the root cause of the etiological factor. If mesenchymal stem cells are completely absent, it can be assumed that the body's defenses are exhausted. (in this case, the patient died after four weeks). A significant number of hematopoietic stem cells show that the generalization process occurs through these stem cells.

Mesenchymal stem cells (MSCS) are the precursors of a number of human tissues and have a wide range of possible applications in medicine. The uniqueness of MSCS is that when cells are

grown outside the body, they multiply rapidly, but do not differentiate into anything specific until a unique stimulus is applied. The peculiarity of mesenchymal cells is their ability to give rise to many cells such as muscle cells, bone cells, fat cells, and even neurons, and hematopoietic stem cells only all blood cell lines ( <https://www.differencebetween.com/difference-between-mesenchymal-and-hematopoietic-stem-cells/>).

Stem cells are undifferentiated or non-specialized cells present in our bodies. They are able to divide and give the same type of stem cells or differentiate into specialized cells in tissues that have specific functions. These features of stem cells make it possible to apply them in regenerative medicine. These two types of stem cells each perform certain functions. Presumably, hematopoietic stem cells are more differentiated than mesenchymal stem cells. Mesenchymal stem cells are a type of adult stem cells that are multipotent and can differentiate into several different specialized cell types, including cells of neurons, bones, cartilage, muscle, and adipose tissue. These cells are stromal cells or connective tissue cells. Mesenchymal stem cells are small in size with thin processes on the surface.

Pluripotent stem cells are also hematopoietic stem cells, which are especially abundant in the bone marrow of flat bones. Hematopoietic stem cells provide the hematopoietic system with all the necessary cells. Therefore, the process of differentiation of hematopoietic stem cells (hematopoiesis) mainly occurs in the bone marrow. Since hematopoietic stem cells can form any type of blood cell, they are also called blood stem cells. In addition to the bone marrow, there are few hematopoietic stem cells in the peripheral blood and cord blood.

Hematopoietic and mesenchymal stem cells of the bone marrow are multipotent. They can differentiate into different types of specialized cells. They are found in tissues throughout the body. They are also found in cord blood, cord tissue, and placental tissue. Both types of cells are used in the repair and regeneration of damaged tissue. The bone marrow contains both of these types of cells. Mesenchymal stem cells facilitate hematopoiesis.

Mesenchymal stem cells are multipotent stem cells that can differentiate into cells of neurons, bones, cartilage, muscle, and adipose tissue, whereas hematopoietic stem cells are multipotent stem cells that can differentiate into any type of blood cell. The main difference

between mesenchymal and hematopoietic cells is differentiation into different end cells.

Mesenchymal stem cells are now found in many tissues. Hematopoietic stem cells are found in the bone marrow and peripheral blood, especially in cord blood. Both types of cells are of great importance in the treatment of diseases. Mesenchymal stem cells are used in the treatment of diabetes, heart disease, liver disease, stroke injuries, spinal cord injuries, lung cancer, etc., while hematopoietic stem cells are used in the treatment of blood and bone diseases, including blood cancer, autoimmune disorders. And some genetic disorders, etc. So this is also the difference between mesenchymal and hematopoietic stem cells.

Hematopoietic and mesenchymal stem cells ensure the restoration of tissues and organs in case of damage, ensuring the functional state of the body as a whole. Each type of these cells ensures the constancy of the cellular composition of blood and tissues (<https://www.differencebetween.com/difference-between-mesenchymal-and-hematopoietic-stem-cells/>). Mesenchymal stem cells can differentiate into cells of neurons, bones, cartilage, muscle, and adipose tissue, while hematopoietic stem cells can differentiate into blood cells of any type. In addition, mesenchymal stem cells are present in bone marrow. Mesenchymal stem cells have a higher differentiation potential and create a greater variety of cells. In hematopoietic stem cells, it is much lower, they are responsible for the presence

First of all, a hematopoietic cell is a cell that gives rise to all blood cells. Over time, it differentiates and forms certain histogenetic series for white blood cells, red blood cells, and platelets. All these seemingly different cells came from a single cell. The hematopoietic cell is the least immature. The process of its maturation and hematopoiesis begins directly in the red bone marrow under the action of certain components such as macrophages, reticulocytes, cytokines, and growth factors. Stem hematopoietic cells, as well as mesenchymal cells, are used for transplantation, receiving them from the bone marrow and cord blood

By their nature, mesenchymal stem cells (MSCS) and hematopoietic cells share a common ancestor. However, in the process of differentiation, they have taken very different paths histogenesis. Thus, MSCS gives rise to the connective tissue itself, the cells lining the vessels, and other mesenchyma derivatives.

Accordingly, getting it will be the same, but

the application will be different. Violation of the processes of regenerative regeneration of an organ, accompanied by a lack of its function, is characterized by growing and not compensated cell death. This is facilitated by violations of information intercellular interaction, regulated primarily by cells of the immune system, and deep inhibition of migration activity of stem and progenitor cells that provide structural replacement of differentiated dead cells. The bone marrow is the only organ in which two different types of stem cells coexist and interact functionally.

The main functions of bone marrow MSCs are 1. Formation of a hematopoietic microenvironment (GIM). 2. The formation of a stromal microenvironment. 3. Participation in morphogenesis. 4. Self-maintenance and recovery of the MSK pool. 5. Participation in homeostatic reactions of the body and in the processes of regeneration, repair, and adaptation of the mesenchymal cell system in normal and pathological conditions.

Mesenchymal stem cells play an important role in the capture of hematopoietic stem cells by the stroma (extracellular matrix and stromal cells), differentiation of hematopoietic cell precursors into Mature cells under the influence of various secretory factors. It is assumed that the study of mesenchymal stem cells of the bone marrow in various diseases of the hematopoietic system will help to detect the mechanisms of regulation and maintenance of normal hematopoiesis.

Along with the increased interest in mesenchymal stem cells, the vast majority of research is conducted with samples of mesenchymal stem cells from healthy subjects and removed from various areas. On the other hand, the presence of various pathologies of hematopoietic cells, such as leukemia, suggested the presence of possible compensatory adaptive changes in mesenchymal stem cells, which are components of the bone marrow microenvironment, the study of which will lead to a better understanding of the mechanism of the development of blood pathology.

## 5. ETHICS:

Permission was obtained from the Ethics Committee to conduct this study (Protocol No. 56/2014).

## RESUMO

Neste relatório, filmes finos nanocristalinos de TiN foram depositados em substratos de vidro e Ti-6Al-4V utilizando o processo de pulverização por magnetron DC. Os filmes de TiN foram pulverizados usando um alvo de Ti puro (99,9%) com 40W de potência em atmosfera de mistura de gás Ar/N<sub>2</sub>. A estrutura dos filmes de TiN foi caracterizada por difração de raios-X, já que os filmes preparados exibiam uma orientação preferida (200), enquanto o filme recozido a 500 °C mostra os (111), (200) e (311). Filmes de TiN policristalinos, cúbicos e orientados a (111) foram produzidos com temperatura de recozimento de 500 °C. O efeito da temperatura depositada nas morfologias microestruturais dos filmes finos foi estudado por Microscópio Eletrônico de Varredura por Emissão de Campo (FESEM). O tamanho das partículas dos filmes de TiN pulverizados variou de 50 a 70 nm e foi fortemente influenciada pelas temperaturas de recozimento, a morfologia dos filmes depositados antes e após o recozimento apresenta uma aglomeração característica de partículas. A análise de polarização potenciodinâmica dos filmes de TiN confirma a relação inversa entre resistência de polarização e corrente de corrosão. Também foram obtidas as medidas de biocorrosão para filmes de TiN depositados no substrato Ti-6Al-4V em solução de NaCl a 3,5%. Foi observada uma clara melhoria na resistência à corrosão, e em oposição as não tratadas, especialmente para amostras de TiN/Ti-6Al-4V com recozimento térmico (500 °C). A taxa de corrosão foi de 0,1458 mm/ano para a amostra não revestida, enquanto que nas amostras de TiN/Ti-6Al-4V após o recozimento foi de 2,668·10<sup>-4</sup> mm/ano. O potencial médio de corrosão calculado foi 0,117 V. Os resultados confirmaram que as ligas revestidas com tratamento térmico a 500 °C exibiram um melhor comportamento eletroquímico em comparação com as ligas não revestidas e não tratadas termicamente, possivelmente devido ao melhor grau de coesão dos revestimentos.

**Palavras-chave:** Técnica PVD, filmes finos, nitreto de titânio, liga Ti-6Al-4V, biocorrosão.

## ABSTRACT

In this report, TiN nanocrystalline thin films were deposited on glass and Ti-6Al-4V substrates using a DC-magnetron sputtering technique. The TiN films were sputtered using a pure Ti target (99.9%) with 40W of power in Ar/N<sub>2</sub> gas mixture atmosphere. The structure of the TiN films was characterized by X-Ray diffraction, as prepared films exhibited a (200) preferred orientation, while film annealed at 500 °C shows the (111), (200) and (311). Polycrystalline, cubic, (111)-orientated TiN films were produced by annealing temperature of 500 °C. The effect of deposited temperature on the microstructural morphologies of the thin films was studied by Field Emission Scanning Electron Microscope (FESEM). The particle size of the sputtered TiN films ranged from 50 to 70 nm and was strongly influenced by annealing temperatures, the morphology of the films deposited before and after annealing has a characteristic agglomeration of particles. Potentiodynamic polarization analysis of the TiN films confirms the inverse relationship between polarization resistance and corrosion current. The biocorrosion measurements for TiN films deposited on the Ti-6Al-4V substrate in 3.5% NaCl solution have also been obtained. Clear improvement in the corrosion resistance was observed rather than for untreated, especially for thermally annealed (500 °C) TiN/Ti-6Al-4V samples. The corrosion rate was 0.1458 mm/y for the uncoated sample, while 2.685·10<sup>-4</sup> mm/y for TiN/Ti-6Al-4V in samples after annealing. The average corrosion

potential calculated was - 0.117 V. The results confirmed that coated alloys with 500 °C thermally treated exhibited a better electrochemical behavior compare with uncoated and non-thermally treated alloys possibly due to the better cohesion degree of the coatings.

**Keywords:** PVD technique, thin films, titanium nitride, Ti-6Al-4V alloy, biocorrosion.

## المخلص

في هذا البحث، تم إجراء هذه الدراسة من أجل زيادة مقاومة التآكل البيولوجي للأغشية الرقيقة النانوية TiN المرسبة بإحدى طرائق التبخير الفيزيائية (Physical Vapor Deposition). تم ترسيب الأغشية الرقيقة النانوية TiN على ركائز الزجاج وسبيكة Ti-6Al-4V باستخدام تقنية الترديد الماكنتروني للتيارات المستمرة. حيث تم ترديد الأغشية الرقيقة باستخدام هدف من التيتانيوم النقي (Ti) بقوة 40 W تحت خليط من غاز الأركون والنيتروجين Ar/N<sub>2</sub>. شخص التركيب البلوري للأغشية الرقيقة TiN باستخدام تقنية حيود الأشعة السينية X-Ray. حيث أظهرت الأغشية الرقيقة المطلية على الزجاج اتجاهها (200)، بينما بعد التلدين وعند درجة حرارة 500 درجة مئوية أظهرت مزيج من الاتجاهات (111)، (200) و (310). نستنتج من ذلك أن الغشاء الرقيق TiN ذات اتجاه (111)، مكعبي و Polycrystalline. بعد ذلك، تم دراسة تأثير الحرارة على التركيب النانوي للغشاء الرقيق المشخص باستخدام المجهر الإلكتروني الماسح (FE-SEM)، وبفعل المعالجة الحرارية، ازداد الحجم الحبيبي للأغشية الرقيقة من 50 إلى 70 نانومتر مع زيادة تكتل الحبيبات النانوية للغشاء الرقيق. لقياسات التآكل البيولوجي، تم غمر السبيكة Ti-6Al-4V المطلية بالغشاء الرقيق TiN في محلول كلوريد الصوديوم وبنسبة ( 3.5% NaCl)، إذ تم حساب التآكل البيولوجي لهذا السبائك المطلية وغير المطلية من خلال Potentiodynamic Polarization. لوحظ أن مقاومة التآكل للغشاء الرقيق المملن ازدادت بشكل واضح، بالإضافة إلى أن معدل التآكل للسبيكة النقية (غير المطلية)  $0.1458 \text{ mm/y}$  إلى  $2.685 \times 10^{-4} \text{ mm/y}$ ، بينما معدل التآكل للسبيكة المطلية والمملنة انخفض إلى  $2.685 \times 10^{-4} \text{ mm/y}$ . أظهرت النتائج أن المعالجة الحرارية حسنت من صفات السبيكة المطلية والمعالجة حرارياً عند درجة حرارة 500 درجة مئوية وأيضاً أظهرت هذه السبائك سلوكاً كهروكيميائياً أفضل بالمقارنة مع السبائك غير المطلية وغير المملنة ربما بسبب درجة التماسك الأفضل للطلاء.

**الكلمات المفتاحية:** تقنية الترسيب التبخير الفيزيائية، الأغشية الرقيقة، نيتريد التيتانيوم، سبيكة Ti-6Al-4V، التآكل البيولوجي

## 1. INTRODUCTION:

Titanium nitride has shown its potential application in various industries including an anti-corrosive coating or a hard coating on cutting tools because of its important properties such as corrosion resistance and high hardness (Borah, Pal, Bailung, and Chutia, 2008; Fenker, Balzer, Kappl, and Banakh, 2005). TiN thin films have been prepared using several methods such as electrodeposition (Ma, Jiang, and Xia, 2017), dynamic mixing (Takano, Isobe, Sasaki, and Baba, 1989), hollow cathode discharge ion plating (Chou, Yu, and Huang, 2001), and pulsed laser deposition (Xu, Du, Sugioka, Toyoda, and Jyumonji, 1998). However, DC-magnetron sputtering was mostly used to deposit TiN thin films, and this method presents a high ionization rate (> 40 %) which make it a good technique to obtain dense coatings (Kouznetsov, Macak, Schneider, Helmersson, and Petrov, 1999; Manouchehri, AlShiaa, Mehrparparvar, Hamil, and Moradian, 2016; Paulitsch, Mayrhofer, Münz, and Schenkel, 2008; Paulitsch, Schenkel, Zufraß, Mayrhofer, and Münz, 2010), as well as good mechanical properties, increase the adhesion between the film and the ceramics and/or metals substrates (Schönjahn *et al.*, 2000). The deposition of TiN using magnetron sputtering has significant specific advantages such as low levels of impurities and easy control of the deposition rate. This method enables the production of thin films in various morphology and crystallographic structures (Kelly and Arnell, 2000; Khalaf,

Hassan, Khudiar, and Salman, 2020).

The use of Ti and TiN films as protective coatings is rapidly growing so that it is important to know their corrosion properties. Also, Ti compounds and its alloys such as Ti-6Al-4V and TiN, in particular, are being increasingly used as biomaterials (Manso-Silvan, Martínez-Duart, Ogueta, García-Ruiz, and Pérez-Rigueiro, 2002), they also have excellent properties, e.g., biocompatibility, corrosion resistance, low density, mechanical strength, and relatively low cost. These properties make titanium and its alloys a potential dental implant material. Among these features, the corrosion resistance is of great importance, not only because it determines the device's service life, but also because of the harmfulness of the corrosion processes taking place in the living organism (Veiga, Davim, and Loureiro, 2012).

This paper reports data for TiN thin films grown on glass and Ti-6Al-4V substrates by using DC magnetron-sputtering deposition. The corrosion behavior was investigated by measuring the polarization curve (Tafel). We focus on the annealing temperature in controlling the structural and corrosion properties of the TiN films produced.

## 2. MATERIALS AND METHODS:

### 2.1. Experimental

TiN thin films were deposited on glass,

and Ti6Al4V substrates by D.C were sputtering. The glass substrates were cleaned ultrasonically by ethanol and deionized water for 15 min before sputtering and then loaded to the substrate holder of the sputtering machine. Corning # 7059 glasses (30 × 40 × 1.2 mm<sup>3</sup>) were used, while the Ti-6Al-4V samples were cut to 20 mm × 20 mm diameter then grinded by 500 microns SiC grinding paper. The substrates were cleaned by using ultrasonic twice in ethanol 96% (Sigma Aldrich, England), then by distilled water for 15 min and allowed to dry in discaiter at room temperature for 24 h (Hamil, Siyah, and Khalaf, 2020). The sputtering target was a pure Ti disc (99.99%, 2 inches, and diameter 5 mm thick). The base pressure was 1·10<sup>-5</sup> Torr, and the sputtering was carried out in Ar:N<sub>2</sub> (90:10) atmosphere. Before starting the deposition, the target was pre-sputtering for 15 min with a shutter located between the target and substrate. During all depositions, the target to substrate distance and sputtering power were adjusted at 60 mm and 40 W, respectively. The pressure of the sputtering chamber was pumped down to 5·10<sup>-3</sup> Torr before deposition. Then nitrogen gas was introduced into the chamber, and the required pressure was set. After that, argon gas was introduced until the preset pressure was reached.

When the preset total pressure was reached, the nitrogen was shut off, and the target was preset in an argon atmosphere for around 10 min to avoid the target's surface oxide layer. After presputtering, the nitrogen gas was again introduced into the chamber with a flow rate ratio of Ar(90)/N<sub>2</sub>(10), and the sputtering process starts. The sputtering conditions are listed in Table 1.

The structural properties of TiN films were obtained by the X-ray diffraction (Philips Geiger using CuKα ( $\lambda = 1.54 \text{ \AA}$ ). The FE-SEM (TESCAN MIRA3) was used to observe the morphology of the films. The corrosion process was determined using ASTM G1-03/ASTM G102, and the corrosion behavior was investigated by measuring the polarization curve (Tafel).

### 3. RESULTS AND DISCUSSION:

#### 3.1 X-Ray diffraction

Figure 2 shows X-ray diffraction patterns of the samples before and after heat treatment at 500 °C for 2 h. The low intensity of the X-ray diffraction peaks, as well as its large widths, clearly indicates that the deposited films are not fully crystalline and that a large fraction of the

films are still amorphous and are in agreement with previous studies (Vasu, Krishna, and Padmanabhan, 2011). As-deposited Titanium nitride films deposited before thermal annealing shows a single crystalline peak corresponding to a plane (200) at  $2\theta = 36.86^\circ$  for comparison (JCPDS file number 77-1893) (Vasu *et al.*, 2011). The Bragg angle of the plane (200) had shifted to another angle. Close examination of the XRD pattern of the thermally annealed films deposited at 500°C with deposition time 2 h revealed that the tetragonal TiN phase had appeared more clearly with planes (111) and (311) (Chawla, Jayaganthan, and Chandra, 2008; Fenker *et al.*, 2005). At 500 °C thermally annealed thin films, the intensity of the Bragg reflections had increased in comparison with the as deposited thin films, at higher annealing temperatures, thermal energy enhances the mobility of the active sites, and this leads to grain growth (Kavitha, Kannan, Reddy, and Rajashabala, 2016), which is evidence for improved crystallinity.

The XRD pattern of the deposited film shows a weak peak at  $37^\circ$ , which can be related to the (111) crystallographic orientations of TiN with a face-centered cubic (FCC) structure (JCPDS card number 02-1159) (Kavitha *et al.*, 2016). It is known that the FCC structure of TiN may form when nitrogen atoms occupy all the octahedral sites of titanium with hexagonal close-packed (HCP) or body-centered cubic (BCC) structures. This transformation in titanium structure from HCP and BCC to FCC occurs due to the accommodation of nitrogen atoms with a small size in the interstitial sites of Ti with the larger size. The absence of a titanium peak in the XRD pattern demonstrates the absence of Ti atoms in the structure of the films and completes the nitride formation process. The competition between the surface energy, the strain energy, and the stopping energy of different lattice planes of a film affect the preferred orientation and lowest total energy of the film (Pelleg, Zevin, Lungu, and Croitoru, 1991; Zhao *et al.*, 1997). In the case of TiN film, the direction of the lowest energy is (111) direction. Annealing, the film did not influence the preferred orientation but increased the intensity of the peak. By increasing the annealing temperatures to 500 °C, TiN (111), peak intensity is increased. Thermal energy produced by annealing leads to the enhancement of mobility of active sites. The increase of mobility can be attributed to grain growth and the reduction of defects during the annealing treatment (Wang *et al.*, 2013).

### 3.2 Surface morphology of the TiN layers

Typical FESEM images of TiN films deposited on glass substrates under different deposition currents, before and after annealing at 400 and 500 °C, are shown in figure 3 (a – f). The amorphous particles and nonuniform clumps were observed before heat treatment. The agglomeration of the particles resulted in the formation of clusters. The FESEM micrograph of as-deposited TiN revealed that the average particle size of TiN is in the range of (25 nm). It is found that the TiN crystallite size has been increased after annealing, where the average particle size of TiN coated at 400, and 500 °C increased to 50 nm to 70 nm, respectively. The increase in annealing temperature (i.e., The crystallinity of the film increases), provides extra energy to the adatoms and results in increasing order of the microstructure and particle size. However, the excessive supply of annealing temperature may cause a degradation of the preferred orientation, and the film will suffer from the bombardment of highly energized particles, resulting in internal defects of the film (Chen, McEwen, Zaveri, Karpagavalli, and Zhou, 2012).

### 3.3 Corrosion measurements

Various electrochemical techniques have been applied to study the behavior of corrosion, for example, potentiodynamic polarization (Tafel analysis). Tafel analysis is a well-established electrochemical technique, and the current is recorded when the open-circuit potential is imposed on a metal sample. The corrosion rate calculated from combined Equation 1 and 2 (Chen *et al.*, 2012; Hamil *et al.*, 2020), polarization resistance ( $R_p$ ) has an inverse relationship with corrosion current.

$$I_{corr} = \frac{\beta_a \beta_c}{2.3 R_p (\beta_a + \beta_c)} \quad (\text{Eq. 1})$$

Where,  $\beta_a$  = anodic Tafel slope,  $\beta_c$  = cathodic Tafel slope.

$$\text{Corrosion Rate (C.R)} = \frac{I_{corr} \times K \times EW}{d \times A} \quad (\text{Eq. 2})$$

K= constant that define the units of the corrosion rate =  $3.272 \cdot 10^{-3}$  mm/( $\mu\text{A}$  year), EW= equivalent weight (g/equivalent) = 11.768 g/eq., d = density ( $\text{g/cm}^3$ ) =  $4.420 \text{ g/cm}^3$ , A = sample area ( $\text{cm}^2$ ) =  $0.151 \text{ cm}^2$ .

The polarization curve (Tafel) diagram for TiN coated on Ti6Al4V alloy were presented in figure (4). When the Ti6Al4V alloy was immersed in simulated biological 3.5% NaCl solution (Bodunrin, Chown, van der Merwe, and Alaneme, 2018; Bodunrin, Chown, van der Merwe, and Alaneme, 2019; Dai, Zhang, Zhang, Chen, and Wu, 2016), the average corrosion potential is (-0.117) V. The corrosion potential shifted to the cathode side for samples coated with TiN before, and after annealing, the potential values were -0.0547 and -0.048 V, respectively. Moreover, the corrosion current  $I_{corr}$  was obtained from the polarization curves by extrapolation of the anodic and the cathodic branches of the polarization curve to the corrosion potential. The corrosion current of TiN films before and after annealing were  $4.6323 \cdot 10^{-8}$  and  $4.6541 \cdot 10^{-9}$  A/ $\text{cm}^2$ , respectively. Also, the corrosion rate of coated samples was lower compared with Ti-6Al-4V alloy, and this was expected because the reduction in corrosion rate means the reduction in weight loss from sample material. The weight loss (W) was calculated from Equation 3 (Hamil *et al.*, 2020), Table (2).

$$W = \text{Corr. Rate} \frac{mm}{y} \times \rho \times 3.17 \times 10^{-9} \quad (\text{Eq. 3})$$

Also, open-circuit potential (OCP) is the other typical technique to study the corrosion. Figure (5) shows the variation of OCP with immersion time for TiN coated Ti-6Al-4V alloy in 3.5 NaCl% solution at 25 °C. The initial OCP for uncoated Ti-6Al-4V was -0.772 V, the potential gradually increased to be -0.512 and 0.067 V for the samples TiN coated before and after thermal annealing.

In general, the coated samples show a positive shift in corrosion potential value and decreasing in both corrosion current and corrosion rate values in comparison with the bare substrate. Moreover, a positive shift in corrosion potential value and decreasing in both corrosion current and corrosion rate values with thermal annealing are observed. These results can be ascribed to the formation of a passive layer.

## 4. CONCLUSIONS:

TiN films were prepared by DC-magnetron sputtering technique, film annealed at 500 °C exhibited cubic phase TiN. It has been observed that the particle sizes and corrosion properties were strongly influenced by temperature

annealing, where the average particle size increased to 50 and 70 nm for the films heated at 400 and 500 °C. The corrosion rate of TiN film deposited on Ti-6Al-4V substrate decreased, where it was 0.1458 mm/year for uncoated sample while being  $2.685 \cdot 10^{-4}$  mm/year TiN for the sample annealed at 500 °C, this sample also presents the polarization resistance ( $R_p$ ) of 3247 KΩ/cm<sup>2</sup>, while it was 1.719 KΩ/cm<sup>2</sup> for the uncoated sample.

## RESUMO

Vários polimorfismos em diferentes locos gênicos afetam características de produção, como rendimento e composição do leite. O presente estudo teve como objetivo determinar a frequência alélica e genotípica do gene *DGAT1* e avaliar as associações entre variantes genéticas do *DGAT1* e produção de leite e sua composição química de bovinos iraquianos locais. Amostras de sangue de 100 vacas foram obtidas para isolamento do DNA. O iniciador usado neste estudo amplificou fragmentos de 411-pb no exon 8 do gene *DGAT1*. Métodos de sequenciamento de DNA foram aplicados para detectar polimorfismo de nucleotídeo único do gene *DGAT1* em 100 vacas. As sequências nucleotídicas do exon 8 do gene *DGAT1* foram registradas para bovinos iraquianos locais no Centro Nacional de Informações de Biotecnologia (NCBI), Banco de Dados de DNA do Japão (DDBJ) e Arquivo Europeu de Nucleotídeos (ENA) sob os seguintes números de acesso (LC492073 e LC492074). Os resultados mostraram a presença de dois sítios polimórficos, levando à construção de 2 haplótipos diferentes na vaca. A diversidade de haplótipos foi de 0,536, enquanto a diversidade de nucleotídeos foi de 0,0031. Foram detectados dois locais de polimorfismo de nucleotídeo único (SNP) do gene *DGAT1*, a saber A10433G (A / G) e A10434C (A / C). O resultado dessa mutação altera a substituição da lisina por alanina na posição 232 (mutação A232K) da sequência de aminoácidos. O software genético V. 2020.0.4 foi utilizado para detectar genótipos do gene *DGAT1*, pois o alinhamento da sequência mostrou a presença de três genótipos. As frequências genotípicas de KK, KA e AA foram de 0,40, 0,30 e 0,30, respectivamente. As frequências dos alelos K e A foram de 0,60 e 0,40, respectivamente. O genótipo KK foi significativamente ( $P < 0,05$ ) associado ao maior rendimento de gordura. Portanto, o gene *DGAT1* poderia servir como um marcador genético para a seleção do rendimento de gordura em vacas.

**Palavras-chave:** Gene *DGAT1*, gado iraquiano local, produção de leite, polimorfismo de nucleotídeo único.

## ABSTRACT

Several polymorphisms in different gene loci have been noted to affect production traits such as milk yield and milk composition. The present study aimed to determine the allelic and genotypic frequency of the *DGAT1* gene and evaluate the associations between *DGAT1* genetic variants and milk yield and its chemical composition of local Iraqi cattle. Blood samples from 100 cows were obtained for DNA isolation. The primer used in this study amplified 411-bp fragments at exon 8 of the *DGAT1* gene. DNA sequencing methods were applied to detect single nucleotide polymorphism of the *DGAT1* gene in 100 cows. The nucleotide sequences of exon 8 of the *DGAT1* gene were registered for local Iraqi cattle in the National Center for Biotechnology Information (NCBI), DNA Data Bank of Japan (DDBJ), and the European Nucleotide Archive (ENA) under the following accession numbers (LC492073 and LC492074). The results showed the presence of two polymorphic sites leading to the construction of 2 different haplotypes in the cow. Haplotype diversity was 0.536, while nucleotide diversity was 0.0031. Two single-nucleotide polymorphism (SNP) loci of the *DGAT1* gene were detected, namely A10433G (A/G) and A10434C (A/C). The resulting of this mutation changes lysine to alanine substitution at position 232 (A232K mutation) of amino acid sequence. Geneious software V. 2020.0.4 was used to detect genotypes of the *DGAT1*

gene, as the sequence alignment showed the presence of three genotypes. The genotypic frequencies of KK, KA, and AA were 0.40, 0.30, and 0.30, respectively. Frequencies of K and A alleles were 0.60 and 0.40, respectively. The KK genotype was significantly ( $P < 0.05$ ) associated with higher fat yield. Therefore, the DGAT1 gene could serve as a genetic marker for the selection of fat yield in cows.

**Keywords:** DGAT1 gene, local Iraqi cattle, Milk yield, single-nucleotide polymorphism.

## الخلاصة

العديد من التشكلات الوراثية في عدة مواقع جينية تم ملاحظة تأثيراتها في الصفات الانتاجية مثل انتاج الحليب ومكوناته. تهدف الدراسة الحالية قياس التباين الوراثي وتحديد تكرار الاليلات والتركييب الوراثية لجين DGAT1 وعلاقتها بأنتاج الحليب ومكوناته الكيميائية في الماشية المحلية العراقية. تم الحصول على عينات الدم من 100 بقرة لغرض استخلاص الحامض النووي منقوص الاوكسجين. البادئات المستخدمة في هذه الدراسة لتضخيم قطعة بطول 411 زوج قاعدي في الاكسون الثامن من جين DGAT1. استعملت تقنية تتابعات الحامض النووي منقوص الاوكسجين لغرض تحديد التشكلات الوراثية للنوكليوتيدات المنفردة. تم تسجيل تسلسل النوكليوتيدات exon 8 من جين DGAT1 للماشية المحلية العراقية في المركز الوطني لمعلومات التكنولوجيا الحيوية (NCBI) وبنك بيانات الحامض النووي الياباني (DDBJ) وأرشيف النوكليوتيد الأوروبي (ENA) تحت أرقام الانضمام التالية (LC492073 و LC492074). أظهرت النتائج وجود نمطين فرديين (H) نتج عنهما تشككين وراثيين (NH) في الالبغار المدروسة. كانت قيمة تنوع النمط الفردي 0.536 بينما كانت قيمة تنوع النوكليوتيدات 0.0031. تم تحديد تشككين وراثيين للنوكليوتيدات المنفردة (SNP) في جين DGAT1 هما A10433G و A10434C نتج عنها تغير الحامض الاميني اللابسين الى الحامض الاميني الالنين في الموقع 232 (A232K) من تسلسل الاحماض الامينية. استخدم برنامج Geneious (V. 2020.0.4) للكشف عن التراكيب الوراثية في الجين المدروس، إذ أظهرت محاذاة التتابعات عن وجود ثلاثة تراكيب وراثية. بلغ تكرار التراكيب الوراثية KK و KA و AA 0.40 و 0.30 و 0.30 على التوالي اما تكرار الاليلات K و A كانت 0.60 و 0.40 على التوالي. أظهر التركيب الوراثي KK فرق معنوي ( $P < 0.05$ ) بزيادة نسبة الدهن مقارنة بالتراكيب الوراثية الاخرى لذلك يمكن استخدام هذا الجين كواسم وراثي لعلاقته بدهن الحليب في الالبغار.

**الكلمات المفتاحية:** جين DGAT1، الالبغار المحلية العراقية، انتاج الحليب، التشكلات الوراثية للنوكليوتيدة المنفردة.

## 1. INTRODUCTION:

Iraqi local cattle are scattered on most areas and differ in appearance from each other and are believed to be due mostly to the origins of Indian cows (Zebu) where they have similar characteristics of the species (*Bos Indicus*), which occupy the hot areas, it differs from European cattle belonging to the *Bos Taurus* (Paulson and Thompson, 2015). Among these, Jenoubi is found in the southern, more humid part of Iraq. Alshawi *et al.*, (2019) showed that a significant level of genetic diversity in indigenous Iraqi cattle in line with their history and genome-wide analysis releases the genes that play an important role in immunity (parasitic, bacterial disease) and other environmental adaptive traits (heat tolerance).

The synthesis of milk components has to be increased to improve the efficiency of milk production. This may be carried out by way of combining genetic enhancements and true management, which include improving the availability of the vital nutrients that the udder uses to produce milk. After advances in molecular biology, it became clear that DNA transcription in a laboratory and identifying the form of the genome that made up it became a compelling manner to persuade the phenotypic systems of individuals. In addition to transcription, many post-translation events could significantly affect the phenotype, along with protein phosphorylation constitutes a primary one (Osorio *et al.*, 2016).

The amount of milk, milk fat, and proteins are important traits in the dairy cattle breeding. Milk production depends on the ability of the mammary gland to metabolize fat. Milk fat consists of approximately 98% triglycerides, and the acyl-CoA: diacylglycerol acyltransferase 1 (DGAT1) enzyme has an essential function in milk fat synthesis because it catalyzes the final step in the formation of triglycerides (Lu, *et al.*, 2015). Evidence has pointed to the role of DGAT1 enzyme on milk yield and composition (Cole *et al.*, 2011).

The Diacylglycerol Acyltransferase-1 (DGAT1) gene is one of the functional candidate genes affecting milk composition traits (Juhlin *et al.*, 2012). The cattle DGAT1 gene is located on chromosome 14 and contains 17 exons ((Lešková *et al.*, 2013). The dinucleotide change (AA/GC) at positions 10433 and 10434 (rs AJ318490.1) in exon 8 leads to a non-conservative substitution of Lysine by Alanine at position 232 and has been shown to affect milk yield strongly and milk composition in Italian Holsteins (Bobbo, *et al.*, 2018), White Fulani and Borgou cattle breeds (Houaga *et al.*, 2017) and Holstein, Simmental and Brown Swiss cattle breeds in Croatia (Dokso *et al.*, 2015). In a study, demonstrated that the lysine variant, which represents the "wild type" and is defined by K allele, is characterized by a higher velocity rate in producing triacylglycerols than the A allele (alanine variant) and thus increasing the fat content in animal milk (Grisart *et al.*, 2004). In animals with KK genotype, DGAT1 activity of KK

genotype was reported to be five times higher than AK and AA individuals (Lacorte *et al.*, 2006)

This study aimed to provide an overview of the association between DGAT1 polymorphisms and milk yield and its chemical composition of local Iraqi cattle.

## 2. MATERIALS AND METHODS:

The present study was undertaken in the Genetic Engineering Laboratory, Department of Animal Production, College of Agriculture, University of Basrah, Iraq.

### 2.1. Animals and genomic DNA isolation

The study included the use of 100 Iraqi local cattle. Farmers own the animals used in this study. Before sampling, the objectives of the study were explained to them in their local languages so that they could make an informed decision regarding giving consent to sample their animals. Government veterinary, animal welfare, and health regulations were observed during sampling of the populations analyzed here. The procedures involving animal sample collection also followed the recommendation of directive 2010/63/EU. Collection of blood samples was permitted by the Iraqi Ministry of Agriculture.

The blood samples (5ml/cow) from the jugular vein were collected and immediately transported to the laboratory in a cool box containing ice and stored at  $-20^{\circ}\text{C}$  until further analysis. A 50 ml tubes were used to collect milk samples and sent to the physiology laboratory (College of Agriculture, University of Babylon) for the analysis of milk components by Funke Gerber, Germany.

Genomic DNA was extracted from the whole blood using gSYNC™ DNA Extraction Kit manufactured by the Taiwanese Geneaid company. The DNA concentration was determined using Nanodrop Thermo scientific spectrophotometer (260/280) and then diluted to the final working concentration of a 50 ng/ $\mu\text{l}$ . A fragment (411bp) of the DGAT1 gene in cattle by using the primer F: 5'-GCACCATCCTCTTCTCAAG-3' and R: 5'-GGAAGCGCTTTCGGATG-3' (Kaupe *et al.*, 2004). The PCR amplifications were conducted in a 50  $\mu\text{l}$  volume containing 6  $\mu\text{l}$  genomic DNA, 25  $\mu\text{l}$  of Master Mix, 2  $\mu\text{l}$  each primer, 15  $\mu\text{l}$  free water. The amplification conditions included one cycle of denaturation at  $94^{\circ}\text{C}$  for 2 min and 35 cycles for 30 min, 30 sec of annealing at  $59^{\circ}\text{C}$ , and extension at  $72^{\circ}\text{C}$  for 45 sec, as well as the final extension at

$72^{\circ}\text{C}$  for 10 min. The PCR results were extracted using apparatus at 2% agarose gel with the visualized by contact with ultraviolet light. The PCR product was sequenced by Yang ling Tianrun aoka biotechnology company.

### 2.2. Data analysis

The sequencing results of the DGAT1 gene were compared with accession No. MF351623 at the NCBI by BioEdit 7.0 software (Hall, 1999). Haplotype diversity (HD) and nucleotide diversity ( $\pi$ ) were analyzed using DnaSP V5. 10 software (Librado and Rozas, 2009). The Geneious prime (version 2020.0.4) program was used to detect genotypes.

### 2.3. Statistical analysis

The Completely Randomized Design (CRD) was used to analyze the production data studied within the SPSS (2016) Statistical program Version 24. Least Significant Test within the program was performed to compare different means.

## 3. RESULTS AND DISCUSSION:

The nucleotide sequences of exon 8 of the DGAT1 gene were registered for Iraqi local cattle in the National Center for Biotechnology Information (NCBI), DNA Data Bank of Japan (DDBJ), and the European Nucleotide Archive (ENA) under the following accession numbers (LC492073 and LC492074).

### 3.1. Genetic Diversity

The results of the genetic diversity of the DGAT1 gene showed that their total number of sequences (N) was 100, and the number of haplotypes (H) was 2 haplotypes resulting in 2 genetic polymorphisms (NH). The values of haplotype diversity (HD) and nucleotide diversity ( $\pi$ ) were 0.536 and 0.0031, respectively (Table 1).

The results in Figure 1 and Table 2 showed the analysis of nucleotides and protein of exon 8. They recorded two SNPs; adenine (A) to guanine (G) and adenine (A) to cytosine (C) in position 10433 and 10434, respectively. Thus, the amino acids changed to A232K.

The sequencing analysis of the DGAT1 gene at exon 8 revealed three genotypes namely, KK, KA and AA in this fragment (Figure 2). The genotypic frequencies are shown in Table 3 (0.40, 0.30 and 0.30 respectively). Two different alleles K and A were identified. All alleles were present in

the studied animals but at different frequencies (0.60 and 0.40, respectively).

In this study, the higher frequency of the K allele (lysine variant, 0.60) at the DGAT1 locus was in line with reported frequencies in Kenya (Houaga *et al.*, 2017) alleles were 0.91 and 0.77 in White Fulani and Borgou breeds respectively, Croatia (Dokso *et al.*, 2015), New Zealand (Spelman *et al.*, 2002) and Greece (Oikonomou *et al.*, 2009), with values of 0.77, 0.60 and 0.62, respectively. But slightly different from other regions in German (Kaupe *et al.*, 2007), UK (Banos *et al.*, 2008), Polish (Nowacka-Woszek *et al.*, 2008) and France (Vanbergue *et al.*, 2016) Holsteins showed very similarly K allele frequency, ranging from 0.53 to 0.55. The differences in DGAT1 gene allele frequencies in different countries and regions may be due to differences in inbreeding and selection programs.

### 3.2. DGAT1 Polymorphisms and Milk Chemical Content

The present study supports the hypothesis that genotypes located within the DGAT1 gene may be associated with milk production traits in dairy cattle. The results were consistent with work in dairy cattle showing that the allele responsible for lysine (K) is usually associated with increased milk fat (Table 4). As in the following studies in Denmark (Bovenhuis *et al.*, 2015), Croatia (Dokso *et al.*, 2015) and Kenya (Houaga *et al.*, 2017). However, the effect of diallelic DGAT1 on milk production traits also can be partly explained by the presence of multiple alleles in the locus of DGAT1 or other mutations in genes closely related (Kühn *et al.*, 2004). The K allele is associated with a high-fat yield in milk (Argov-Argaman *et al.*, 2013), the A allele is associated with high milk yield (Marchitelli *et al.*, 2013). Previous studies on *Bos Taurus* and *Bos indicus* had determined the K allele index as a wild type and inferred that the replacement of A allele had occurred after the separation of the *Bos Taurus* and *Bos indicus* lineages (Kaupe *et al.*, 2007). It was well documented that DGAT1 encoded an enzyme play a major role in the synthesis of triglycerides (Ali, 2015). Triglycerides are the major components of fat are formed by binding of diacylglycerol to long-chain fatty acyl-CoAs. These reactions controlled by some enzymes, one of them encoded by the DGAT1 gene (Klimov, *et al.*, 2018). After these findings, DGAT1 was recommended as a functional candidate gene for milk production traits (Houaga *et al.*, 2018).

## 4. CONCLUSIONS:

A significant association between the KK genotype of the DGAT1 gene with higher fat yield in Iraqi local cattle was detected. These results implied that the DGAT1 gene could be great candidate genes or linked to significant genes that affect milk production traits in cattle.

## RESUMO

O problema da corrosão nas fábricas e instalações vitais continua sendo um dos obstáculos mais importantes que atrasam o progresso da produção e o aumento de sua quantidade. Para resolver o problema de corrosão, muitos inibidores inorgânicos e orgânicos têm sido usados. Recentemente, foram utilizados inibidores feitos de extratos vegetais, mais baratos e ambientalmente amigáveis. A inibição do extrato de sementes de abóbora na liga de aço leve à corrosão no meio ácido foi investigada por espectroscopia da impedância eletroquímica, técnica eletroquímica e método de perda de massa com solução aquosa estática ambiental. O efeito das concentrações de inibidores (10-50 mg/L) e o tempo de imersão (1 a 5 h) foram estudados na eficiência da inibição ( $\eta\%$ ) do extrato em aço leve (AL) imerso em uma solução de HCl 0,5 M. Todas as técnicas mostraram resultados muito bons nos valores do coeficiente de inibição. O percentual ótimo de  $\eta$  estava na faixa de 71 a 76%, dependendo do método utilizado. O tempo ideal foi de 5 horas. Os resultados das curvas de Tafel mostraram uma visão clara do comportamento do extrato, que atua como inibidor do tipo misto. Além disso, o teste de microscopia de força atômica foi aplicado para o estudo da morfologia da superfície da liga. Pelo exposto, o extrato de plantas de abóbora pode ser de grande benefício na inibição da corrosão na indústria.

**Palavras-chave:** AFM, Corrosão, Impedância eletroquímica, Polarização potenciodinâmica, Sementes de abóbora.

## ABSTRACT

The problem of corrosion in factories and vital installations remains one of the most important obstacles that delay the progress of production and the increasing of its quantity. To solve the problem of corrosion, many inorganic and organic inhibitors have been used. Recently, inhibitors made from plant extracts, cheaper and environmentally friendly, were used. The inhibition of pumpkin seed extract on the corrosion mild steel alloy in the acidic medium was investigated using spectroscopy of the electrochemical impedance, Electrochemical technique and mass losing method with a static environmental aqueous acidic solution. Effect of inhibitor concentrations (10-50 mg/L) and immersion time (1–5 h) was studied on the inhibition efficiency ( $\eta\%$ ) of the extract on Mild Steel (MS) immersed in a 0.5 M HCl solution. All techniques showed very good matching results in the inhibition coefficient values. The optimum  $\eta\%$  was in the range 71-76% depending on the method used. The optimum time was 5 hours. Tafel curves results showed a clear view of the extract behavior, which acts as a mixed-type inhibitor. Furthermore, the atomic force microscopy test was applied for studying surface morphology of alloy. From the foregoing, the pumpkin plant extract can be of great benefit in inhibiting corrosion in the industry.

**Keywords:** AFM, Corrosion, Electrochemical impedance, Potentiodynamic polarization, Pumpkin seed.

## 1. INTRODUCTION:

The acidic solutions may be used to remove the rust effect in different parts of the industrial processes. For example, diluted hydrochloric acid is used as broadly the pickling of steel alloys in oil and water pipes. Therefore,

different types of inhibitors, which may be organic, inorganic, and natural extracts are widely used to reduce or control the dissolutions of metal (Karthiga *et al.*, 2015; Kliškić *et al.*, 2000).

The organic and inorganic inhibitors had very good anticorrosive activity, but they are toxic to both humans and the environment. These

inhibitors may cause chronic or acute diseases because of damage in tissues of different organ systems or disturbing the vital function of metabolism or enzymic systems. In addition to these hazardous effects, this type of inhibitors is very costly and forced companies to spend millions on them that made the researchers instead of these synthetic inhibitors by naturally ones. Furthermore, this type of inhibitors are environmentally friendly, available sources, and cheap cost (El-Etre, 1998; Zhang *et al.*, 2015).

Up till now, many plant extracts have been investigated for their corrosion inhibitors behavior using acidic media on the mild steel. For example, *Murraya koenigii* (Yadav *et al.*, 2015; Sharmila *et al.*, 2010), *Terminalia chebula* (Patel *et al.*, 2009), *Carica papaya* (Kasuga *et al.*, 2018; Nwigwe *et al.*, 2019), *Nypa fruticans wurmb* (Orubite and Oforka, 2004; Michael and Olubunmi, 2014), *Emblia officianilis* (D'souza and Chattree, 2015; Saratha and Vasudha, 2010), and many other (El-Etre *et al.*, 2003). These studies including the effect of seed, leave or other parts extracts of plants as corrosion inhibitors on the mild steel in various concentrations of acidic media.

The inhibition behavior of *Murraya koenigii* (curry) leaves extract on the corrosion resistance of mild steel (MS) in nitric acid medium has been studied by gravimetric (or weight loss) measurements and scanning electron microscopy (Quraishi *et al.*, 2010). The inhibiting action of the fruit extract of *Terminalia chebula* (TC) on mild steel corrosion in 1 M HCl solution was studied using gravimetric, potentiodynamic polarization, and electrochemical impedance spectroscopy (EIS) techniques. Other plant extracts have been investigated for their corrosion inhibitors behavior using acidic media on mild steel (Oguzie *et al.*, 2014). Many other studies, including the effect of seed, leave or other parts extracts of plants as corrosion inhibitors on the mild steel in various concentrations of acidic media (El-Etre, 2006; Zucchi and Omar, 1985).

The purpose of this research was to study the pumpkin seed extract as a corrosion inhibitor for mild steel (MS) alloy in acidic solution using electrochemical impedance, polarization of the potentiodynamic technique and mass losing method along with the surface morphology study of alloy using Atomic Force Microscopy (AFM).

## 2. MATERIALS AND METHODS:

### 2.1. Preparation of seed extract

Pumpkin seed that collected from the market of Basrah Old City was left to dry and ground to a fine powder. Twelve grams of this plant powder were mixed with D.W. (1000 mL) and subjected to reflux for about three hours. The resulting solution was passed through fine filter paper, and the clear solution was reduced to obtain 1 gram of extracted solid material of the original volume. The resulting new volume was utilized to test the corrosive inhibitor behavior by preparing different concentrations of aqueous solutions 10, 20, 30, 40, and 50 mg/L.

The coupons of mild steel (N80) was used to study the corrosion properties on a supplied from South Oil Company in Basrah that have the composition (wt.%): 0.80% Mn, 0.3% C, 0.22% Cu, 0.07% Ni, 0.05% P, 0.041%S and Fe is the remainder. The coupon was cleaned by smooth emery papers with grade

The coupons were rinsed with D.W. and subjected to degreasing by acetone and left to dry at room temperature, then kept in a desiccator until use. The concentrated HCl was used to prepare the solution of 0.5 M HCl by dilution with D.W. All the experiments were performed and repeated in the static solution.

### 2.2. Mass losing method

The experiments of mass loss were carried out on the mild steel alloy with a coupon dimensions (2.5 cm length) × (2.0 cm width) × (0.025 cm height) in a static solution of 0.5 M HCl with and without plant aqueous extract with diverse concentrations. The mass of each coupon was recorded by a digital sensitive balance with four decimal digital values and then immersed in 100 mL of acid solution with duration times 1 to 5 h at the temperature 25°C.

After every immersing time, the coupon was washed with distilled water, and the weighed again so as to calculate the efficiency of inhibition ( $\eta_{WL}$ ) and the rate of corrosion ( $R_{corr}$ ). For each run, all solutions were freshly prepared, and the temperature of the tested solution was controlled by a thermostatic auxiliary tool to give an accurate value.

Equation (1) used to calculate the corrosion rate ( $R_{corr}$ ) of mild steel (Batah *et al.*, 2017):

$$R_{corr} = \frac{\Delta W * K}{A * D * T} \quad (\text{Eq. 1})$$

$\Delta W$ = mass losing of alloy (g),  $K$ = constant value ( $5.34 \times 10^5$ ),  $A$ = coupon area ( $\text{cm}^2$ ),  $D$ = density of alloy ( $\text{g}/\text{cm}^3$ ) and  $T$ = exposed time (h).

Equations (2) and (3) used to obtain the inhibition efficiency  $\eta_{WL}(\%)$  and the degree of surface coverage  $\theta_{WL}$ , respectively (Fouda *et al.*, 2017):

$$\eta_{WL}(\%) = \frac{W_o - W_i}{W_o} * 100 \quad (\text{Eq. 2})$$

$$\theta_{WL} = \frac{W_o - W_i}{W_o} \quad (\text{Eq. 3})$$

where,  $W_o$  and  $W_i$  ( $\text{mg dm}^{-2}$ ) mass of the coupon after the dipping in acidic solution without or with extracted inhibitor.

### 2.3. Electrochemical measurements

The assays were performed at room temperature using three-electrode electrochemical cells containing a carbon steel working electrode with a  $1 \text{ cm}^2$  surface area, a platinum auxiliary electrode, and a saturated calomel electrode (Reference electrode). The instrument used to obtain the curve of Tafel depends on the automatic changing in the potential electrode within the range from a positive value of 250 mV to the negative value of 250 mV assistant by scan rate of 0.5 mV per second of open circuit potential to investigate the inhibitory effect of the plant extract on the alloy of mild steel corrosion. The corrosion current densities ( $i$ ) were utilized to draw the linear relationship of the Tafel segment. Then finally, the equation (4) used to calculate the inhibition efficiency  $\eta_{pol}(\%)$  from the obtained values of current densities ( $i$ ) (El Aoufir *et al.*, 2017; Abdul-Nabi and Jasim, 2014):

$$\eta_{pol}(\%) = \frac{i - i_o}{i} \times 100 \quad (\text{Eq. 4})$$

where  $i$  and  $i_o$  are the uninhibited and inhibited corrosion current densities, respectively.

### 2.4. Impedance measurements

The impedance tests were investigated by AC signals of amplitude (10 mV) using the frequency spectrum range 100 kHz - 0.01 Hz. The values of charge transfer resistance (CTR) were obtained by Nyquist plots through the measurement of semi-circles diameter. The inhibition efficiency  $\eta_{EIC}(\%)$  of the inhibitor was

calculated from the values of CTR using equation (5) (Yang *et al.*, 2018):

$$\eta_{EIC}(\%) = \frac{R'_{ct} - R_{ct}^o}{R'_{ct}} \times 100 \quad (\text{Eq. 5})$$

where  $R_{ct}^o$  and  $R'_{ct}$  represent the resistance of charge-transfer (RC-T) in the without and in with the diverse concentration of inhibitor.

The values of impedance from the plot were used to obtain the magnitudes of double-layer capacitance ( $C_{dl}$ ) by using the equation (6) (Lgaz *et al.*, 2017):

$$|Z| = \frac{1}{2\pi f C_{dl}} \quad (\text{Eq. 6})$$

## 2.5. Atomic Force Microscopy (AFM)

Atomic Force Microscopy (AFM) model CentaurU HR (Russia) was utilized in Physics and Energetic Faculty, Udmurtia, The Federal Republic of Russia. The alloy of mild steel that used as sections with the dimensions of (length 2.5 cm x width 2.5 cm and height 0.4cm) were subjected to dipping in the specific acidic solution using different concentrations of pumpkin seed extract (10, 20, 30, 40 and 50 mg/L) as corrosive inhibitors at 25°C for 24 h. After this periodic time, the coupons were take out, washed with D.W., left to dry, and then used for AFM tests.

## 3. RESULTS AND DISCUSSION:

### 3.1. Mass losing measurements

Table 1 and Figure 1 represent the output data of the study for the corrosion process of mild steel alloy in the acidic solution of 0.5 M using different amounts of pumpkin seed extract at 25°C. The equations (1), (2) and (3) were used to calculate the corrosion rate ( $R_{corr}$ ), the efficiency of inhibition ( $\eta_{WL}(\%)$ ) and the coverage of surface ( $\theta$ ) values, respectively.

Table 1 and Figure 2 show the effect of concentration of plant extract on the inhibition efficiency, and the results indicate that by increasing the concentration the  $\eta_{WL}(\%)$  increases to reach the best effect of inhibitor at the concentration of 50 mg/L (Lgaz. *Et al.*, 2018). On the other hand, there is decreasing in the corrosion rate with increasing concentration, which gives a significant indication of the effect of the inhibitor on the corrosion process.

### 3.2. Tafel Polarization Measurements

The output data of the polarization measurements are listed in Table 2 for the corrosion of M-steel test in the 0.5 M acidic solution without and with different concentrations of pumpkin seed extract at the temperature of 25 °C. Figure 3 and Table 2 indicate that increasing the concentrations of pumpkin seed gives a significant decrease in reactions of H<sub>2</sub> reduction (cathodic process) and metal dissolution (anodic process). According to these results, the inhibitor gave the mechanisms of mixed type (Babic-Samardzija *et al.*, 2005; Jasim *et al.*, 2017).

The values of  $\eta_{pol}(\%)$  and  $\theta$  from pumpkin seed tests were calculated using Equation 4. Table 2 shows the determined values of  $I_{corr}$ ,  $E_{corr}$ , Tafel slopes ( $\beta_a$  and  $\beta_c$ ) and  $\eta_{pol}(\%)$ . The data indicated that there is an inversing effect between  $I_{corr}$  and the concentrations of pumpkin seed. The values of  $\beta_a$  and  $\beta_c$  remained almost unchanged with the addition of pumpkin seed concentrations, which gave a clear view that the adsorbed inhibitor decreases  $E_{corr}$  without affecting the reaction mechanism.

### 3.3. EIS measurements

EIS technique at OCP in a wide frequency range was used to study the capacitance at metal/electrolyte interface, which related to corrosion processes on the surface of mild steel coupons using the extract of pumpkin seed. Figure 4 shows Nyquist diagram for mild steel alloy dipped in 0.5M HCl solution at 25 °C using a series of concentrations of the extract as an inhibitor and without inhibitor at the certain open circuit potential.

From Figure 4, it's clear that there is increasing in the semi-circle diameter with inhibitor concentration rising. This result referred to the fact about an increase in corrosion resistance of the material. The optimum concentration of the extract was 50 mg/L, which gave  $R_p$  of 2100 reflected inhibition coefficient percentage of 76.19% as compared with the closed values calculated from Tafel and weight loss methods 74.41% and 71.93, respectively.

The opposite frequency values  $f_{max}$  can be used to calculate the magnitudes of electrochemical double-layer capacitance ( $C_{dl}$ ) by utilizing equation (7) (Migahed *et al.*, 2016):

$$C_{dl} = \frac{1}{2 \pi f_{max} R_{ct}} \quad (\text{Eq.7})$$

Where  $f_{max}$  is the opposite frequency when the imaginary component was maximum.

Table 3 referred to the EIS data which showed that the magnitudes of  $\eta_{EIC}(\%)$  and  $R_{ct}$  is proportional to the concentration of inhibitor, whereas the  $C_{dl}$  values are proportional reversibly.

These results may be referred to the lowering of dielectric constant which effect on the rising in the thickness of the adsorbed electric double layer, which referred to the action of the inhibitor molecules as a thin layer to isolate the alloy from acidic solution by mix adsorption mechanism (Jasim *et al.*, 2015).

### 3.4. Morphology analysis by AFM

Figures 5-*i*, 5-*ii*, and 5-*iii* show the images of AFM for clear metal (control), the surface that subjected to corrosion by acidic medium (0.5M HCl) using or not the inhibitor extract. The pictures of the AFM gave a clear view of the smooth surface of the metal by using pumpkin seed extract concentrations inhibitor in 0.5M HCl. Table 4 gives the results of the AFM study represented by the values of  $R_a$  and  $R_q$ . The value of RMS, which equal to 55.2 nm, referred to the smoothing of the metal surface due to the adsorption of plant extract, which prevents the corrosion process as compared with the RMS value in the absence of inhibitor (120nm) (Elmsellem *et al.*, 2014).

## 4. CONCLUSIONS:

The pumpkin seed aqueous extract can be used to inhibit the corrosion of MS in the static acidic medium at 25°C. The optimum concentration of plant extract should be determined and utilized to give perfect protection efficiency. Using of plant extract in the industry as corrosion inhibitor enhances the green chemistry and environment friendly. The pumpkin seed extract gave good corrosion inhibitor efficiency with closed values using different methods. Morphology analysis referred to the excellent inhibitory behavior of the plant extract.

**RESUMO**

O gerenciamento dos recursos de pastagem do Cazaquistão Ocidental é complicado devido à deterioração dos parâmetros físico-químicos dos solos, manifestando degradação e alcalinização como resultado de pastoreio intensivo. A pesquisa teve como objetivo estudar a tecnologia de pastejo de gado para preservar os parâmetros físico-químicos dos solos e aumentar a eficiência do uso de pastagens. A avaliação e análise estatística dos indicadores físico-químicos dos solos foram realizadas com métodos padronizados durante o período de 2018 a 2019, o que permitiu identificar a melhor tecnologia de pastejo. Os resultados da pesquisa mostraram que, sob a influência de pastoreio intensivo, os parâmetros físico-químicos pioraram, foi detectada uma diminuição nas reservas de húmus em 10,88-12,35%, o solo degradado até o terceiro grau e tornou-se alcalino como resultado do aumento da permutabilidade. sódio a 1,65 cmol (equiv.)/kg. A tecnologia de pastejo moderado afeta positivamente os parâmetros físico-químicos dos solos dos ecossistemas de pastagem. Os solos castanhos das pastagens, onde foi aplicada tecnologia moderada de pastejo, permaneceram resistentes à degradação e salinização. Com essa tecnologia, o húmus do solo foi preservado de forma confiável no nível de 1,15-2,50%, o fósforo móvel estava dentro da faixa ideal de 0,87-1,60 mg/100g. Concluiu-se que é importante usar a tecnologia de pastoreio moderado para melhorar o manejo dos recursos das pastagens, que é a novidade científica da pesquisa.

**ABSTRACT**

Managing pasture resources of Western Kazakhstan is complicated due to the deterioration of the physicochemical parameters of soils, manifesting degradation, and alkalinization as a result of intensive grazing. The research has been aimed at studying the technology of cattle grazing for preserving the physicochemical parameters of soils and increasing the efficiency of pasture use. The assessment and statistical analysis of physicochemical indicators of soils were carried out with standard methods during 2018 – 2019, which allowed identifying the most optimal grazing technology. The results of the research showed that under the influence of intensive grazing, physicochemical parameters worsened, a decrease in the humus reserves by 10.88-12.35% was detected, soil degraded to the third degree, and became alkaline as a result of the increase in exchangeable sodium to 1.65 cmol (equiv.)/kg. The technology of moderate cattle grazing favorably affects the physicochemical parameters of the soils of pasture ecosystems. The chestnut soils of the pastures, where moderate grazing technology was applied, remained resistant to degradation and salinization. With this technology, the soil humus was reliably preserved at the level of 1.15-2.50%, mobile phosphorus was within the optimal range of 0.87-1.60 mg/100g. It has been concluded that it is important to use the technology of moderate cattle grazing to improve the management of pasture resources, which is the scientific novelty of the research.

## ABSTRACT

Процесс управления пастбищными ресурсами Западного Казахстана усложняется из-за ухудшения физико-химических показателей почв с проявлением процессов деградации и солонцевания в результате интенсивного выпаса скота. Целью исследований является изучение технологии выпаса с.х. животных для сохранения физико-химических показателей почв и повышения эффективности использования пастбищ. Применение стандартных методов оценки и статистического анализа физико-химических показателей почв проводилось с 2018 по 2019 годы, что позволило выделить наиболее оптимальную технологию выпаса. Результаты исследований показали, что под воздействием интенсивного выпаса ухудшаются физико-химические показатели, выявлено снижения запаса гумуса на 10,88-12,35%, в результате увеличения обменного натрия до 1,65 смol(equiv.)/kg почва деградировалась до 3 степени и перешла в категорию солонцеватой. Умеренная технология выпаса с.х. животных благоприятно действует на физико-химические показатели почв пастбищных экосистем. Каштановые почвы пастбищ, где применялись умеренная технология выпаса сохраняли устойчивость к деградации и осолонцеванию. При такой технологии гумус почвы достоверно сохранился на уровне 1,15-2,50%, подвижный фосфор находился в оптимальных пределах 0,87-1,60 мг/100г. В этой работе был сделан вывод, что важно использовать умеренную технологию выпаса с.х. животных для повышения эффективности управления пастбищными ресурсами, в чем заключается и научная новизна исследований.

## 1. INTRODUCTION:

The global growth of the population (the world's population in 2050 is expected to be about 9.2 billion people), the global climate changes and their adverse effects on the agriculture, the depletion of natural resources, which is of great importance for the development of the world's agriculture, food safety, and new ethical requirements for the producers are the future challenges associated with sustainable management of natural resources, and investments in food production and agriculture (Kučera *et al.*, 2020).

Grasslands, which constitute a significant part of the global ecosystem, occupy 37 % of the Earth's land area and contribute significantly to the food security, providing the largest part of energy and proteins required by ruminant animals for the production of meat and milk. It is believed that proper pasture management and improvement of the state of degraded pastures can play a fundamental role in mitigating the effect of greenhouse gas emissions, especially concerning carbon accumulation and absorption (Conant *et al.*, 2011; O'Mara, 2012; Nordborg and Röö, 2016).

Multiple scientific studies and developments of agricultural and biological scientific institutions show that in order to maintain the pastures' capability of constant seed and vegetative regeneration and reproduction of the required level of feed resources, they are to be

used within the environmental imperative. The first environmental commandment for the rational use of the pastures is the compliance with the principle of matching their natural capacity with the number of grazing animals. Multiyear scientific studies performed in the second half of the 20th century by the scientists from various countries show that, without harm to the subsequent productivity of the pastures, it is possible to withdraw 25 – 75 % of the aboveground plant mass in various natural zones. In the arid conditions of Russia and Central Asia, 60 – 75 % of the annual plants' growth may be withdrawn (Shamsutdinov, 2012; Nasiyev *et al.*, 2015; Gayevskaya and Krasnopolin, 2016; Nasiyev, 2016; Baytkanov, 2017).

One of the essential levers for restoring and preserving the pastures' biodiversity is grazing management and ecological optimization of the grazing load, which would also improve the productivity of the pastures and ensure environmental sustainability and economic efficiency (Costas *et al.*, 2015).

Among the agrotechnical methods of increasing the pastures' productivity, providing rest from grazing for medium- and highly-degraded pastures is of paramount importance. Even one year's rest will allow pastures to significantly restore their sparse grass cover (Loris *et al.*, 2019).

Studies of the scientists from the USA and China have shown reduced productivity and deteriorated state of vegetation in the heavy grazing conditions (Raiymbekov *et al.*, 2017; Kubenkulov *et al.*,

2019). For improving the state and the rational use of pastures, monitoring the current state of pasture soil resources is the priority task.

## 2. MATERIALS AND METHODS:

### 2.1 Study area

The research was conducted during 2018 and 2019 years at the initiative of the Ministry of Agriculture in the territories of three zones of Western Kazakhstan with different types of chestnut soils for detecting changes in the physicochemical parameters of the soil cover under the influence of different technologies of cattle grazing, and efficient managing pasture resources.

*Zone 1* was the dry-steppe zone with the following coordinates of the reference plot and the pastures: reference plot —  $49^{\circ}01'N$ ;  $018^{\circ}27'103''E$ , moderate grazing pastures —  $50^{\circ}57'N$ ;  $050^{\circ}46'390''E$ , weak grazing pastures —  $50^{\circ}57'N$ ;  $050^{\circ}48'049''E$ , and intensive grazing pastures —  $50^{\circ}59'N$ ;  $E050^{\circ}47'223''E$ .

*Zone 2* was the arid steppe zone with the following coordinates of the reference plot and the pastures: reference plot —  $50^{\circ}21'N$ ;  $051^{\circ}00'073''E$ , moderate grazing pastures —  $50^{\circ}19'N$ ;  $050^{\circ}58'091''E$ , weak grazing pastures —  $50^{\circ}19'N$ ;  $050^{\circ}57'064''E$ , and intensive grazing pastures —  $50^{\circ}20'N$ ;  $E050^{\circ}53'225''E$ .

*Zone 3* was the semi-desert zone with the following coordinates of the reference plot and the pastures: reference plot —  $49^{\circ}05'N$ ;  $049^{\circ}08'101''E$ , moderate grazing pastures —  $49^{\circ}08'N$ ;  $048^{\circ}42'751''E$ , weak grazing pastures —  $49^{\circ}09'N$ ;  $E048^{\circ}42'452''E$ , and intensive grazing pastures —  $49^{\circ}08'N$ ;  $048^{\circ}41'017''E$ .

*Soil sampling.* To determine the effect of grazing on these indicators, soil samples were taken at three farms with moderately, weakly, and intensively used pastures located in three zones of Western Kazakhstan with dark chestnut (Haplic, Luvic), chestnut (Luvic Kastanozems) and Light chestnut soils (Calcic Kastanozems) from the 0 – 10 cm, 10 – 20 cm, and 20 – 30 cm layers. To identify the changes in the soil parameters through comparison, soil samples were taken from the reference plots (without grazing) from the 0 – 10 cm, 10 – 20 cm, and 20 – 30 cm layers in each zone. The experiment was repeated four times.

### 2.2 Physicochemical soil analysis

The changes in the physicochemical parameters of pastures were detected both in the

field and in the laboratory environment with the use of modern generally adopted methods.

Soil density was determined in the field environment using cylinder bores by N.A. Kachinsky. In the field, samples were taken from the soil horizon with a cylinder bore with a volume of about 500 cm<sup>3</sup>. At the same time, soil samples were collected in weighing bottles to determine moisture. In the laboratory, the soil was dried at 105°C to constant weight. Knowing the mass of the weighing bottle with dried soil and the mass of the empty weighing bottle, the mass of air-dry soil was found. Then, dividing the mass of dry soil by its volume (ring volume), the density of the soil was established.

The structural state of the soil was assessed by aggregate analysis using the dry sieving method. According to the results of the aggregate analysis, the structural coefficient (Cstr) was calculated, which was understood as the ratio of the number of aggregates from 0.25 to 10 mm (in%) to the total content of aggregates less than 0.25 and more than 10 mm (in%). The more Cstr was, the better the structure of the soil was. A scale developed by S.I. Dolgov and P.U. Bakhtin was used to assess the structural state of soils (Gabdulov *et al.*, 2018).

In the laboratory environment, the soil content of humus, mobile phosphorus, and exchangeable sodium was determined by the analysis of soil samples.

The content of humus in the soil was determined by the method of I.V. Tyurin based on the oxidation of soil organic matter by chromic acid until the release of carbon dioxide. A solution of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in sulfuric acid was used as an oxidizing agent.

Mobile phosphorus compounds were determined by the photometric method of I. Machigin based on the extraction of mobile phosphorus and potassium compounds from the soil with ammonium carbonate solution at a concentration of 10 g/dm<sup>3</sup> with soil to solution ratio of 1:20 and the subsequent determination of phosphorus in the form of a phosphorus-molybdenum blue complex on photoelectric colorimeter and of potassium on a flame photometer (Gabdulov *et al.*, 2018).

The content of exchangeable sodium in the soil was established by the photometric method by extracting exchangeable and soluble sodium with ammonium acetate solution at a concentration of 1 mol/dm<sup>3</sup> with soil sample mass to solution volume ratio of 1:20 and the subsequent

determination of sodium in the extract using a flame photometer. At the same time, soluble sodium in the aqueous extract was determined, and the difference in sodium was calculated. According to the content of the exchangeable sodium in the cation exchange capacity, the degree of soil alkalinization was established.

The degree of soil cover degradation was established by the physical criteria for land assessment approved by the Ministry of Agriculture of the Republic of Kazakhstan (Order No.185 of the Minister of Agriculture of the Republic of Kazakhstan, 2017).

**Statistical analysis.** The results of the studies were statistically processed following the method of the analysis of variance (Dospekhov, 2015) in the Statistica 6.0 application. Two individual samples were analyzed nonparametrically using the Mann-Whitney U-test, and statistical diagrams were made).

### 3. RESULTS AND DISCUSSION:

**Agrochemical parameters of the pastures.**  
**The dynamics of decreasing the humus content.** Studying the content and humus reserves in the pastures of Western Kazakhstan is a prerequisite for assessing their fertility and for addressing the issues of the rational use of pasture ecosystems. In the studies, the content and humus reserves depended on the technology of farm animals' grazing on the pastures. With that, more dynamic changes in the humus content occurred on the pastures with the arid climate of the third semi-desert zone with light chestnut soils. In the pastures with moderate grazing conditions in this zone, the humus content in the 0 – 30 cm soil layer reduced by 0.15 %, compared to the reference. The humus reserves were 44.16 t/ha, which was less by 7.19 %, compared to the reference. The humus content in the pastures with weak grazing conditions on light chestnut soils was 1.25 % with the humus reserves of 46.50 t/ha.

In the territory of the third semi-desert zone, the lowest humus content was found in the pastures with intensive grazing conditions. With the humus content of 0.83 %, the humus reserves in the 0 – 30 cm soil layer were 34.36 t/ha. Compared to the reference, the reduction of the humus reserves amounted to 27.78 %. In terms of the humus reserves, the soil in this plot degraded to the second degree. Since grazing has a significant effect on some ecosystem services (e.g., retention of nutrients, water storage, reduction of pollution), reduction of these

parameters may result in decreased soil fertility and, consequently, land degradation (Mamontov *et al.*, 2012). According to the hypotheses of the authors, a strong change in the content and reserves of humus in the pastures of the third semi-desert zone was the result of excessive loads from farm animals' grazing on the background of the arid climate (Nasiyev *et al.*, 2015).

On dark chestnut and chestnut soils of the pastures in zones 1 and 2 with the technology of weak and moderate grazing, compared to the soil in the reference plots, the humus content reduced insignificantly (from 0.11 to 0.22 %), and the humus reserves in the 0 – 30 cm soil layer amounted to 4.59 – 6.67 %. With a certain degree of conditionality, it may be assumed that the humus in the soil in these zones was as though "preserved" under the influence of grazing, accompanied by the reduced ingress of the live and dead plant materials into the soil. It should be noted that oxidation of the organic matter in the soil does not occur in the pastures, i.e., the phenomena resulting in the dehumification of the arable land due to its annual plowing do not manifest themselves; hummus is not consumed there, and formation of plants biomass changes its species composition and productivity under the influence of failure (Tesla, 2016; Nasiyev and Bekkaliyev, 2019).

In the case of intensive grazing, the content of humus in chestnut and light chestnut soils reduced by 0.35 - 0.42 %, while the humus reserves reduced by 10.88 - 12.35 %. With that, in terms of humus reserves, the soil degraded to the first degree.

The results of the statistical analysis confirmed the dependence of the humus content on the intensity of the pasture use. The intensity of the changes in the humus content was determined by the type of soil and had a negative tendency. This tendency was described by a linear regression equation. The most significant reduction in the percentage of humus with an increase in the grazing intensity was observed in light chestnut soils of the third semi-desert zone (Figure 1).

The changes in the humus reserves also occurred according to the linear function in all types of soil. Regression analysis showed that the highest rate of humus reserves reduction depended on the type of soil and had a linear tendency. The most intensive reduction of humus content in the soil with increasing the intensity of pasture use was observed on the light chestnut

soils of the third semi-arid zone.

*The content of mobile phosphorus and exchangeable sodium.* In chestnut soils, one of the limiting elements of soil fertility is the content of phosphorus (Barbara *et al.*, 2016). In this regard, it is important to maintain the content of mobile phosphorus in chestnut soils in agricultural use. According to the results of the studies, the grazing of farm animals insignificantly changed the content of mobile phosphorus in chestnut soils of the three zones of Western Kazakhstan. In the zone of dark chestnut soils, the reduction of mobile phosphorus content ranged from 0.23 to 0.59 mg/100 g of soil, compared to the reference. In chestnut soils of the pastures in the second zone, the changes in the content of mobile phosphorus from the reference were 0.43 - 0.69 mg/100 g of soil. In the third zone in the light chestnut soils, the content of mobile phosphorus reduced from 0.10 to 0.41 mg/100 g of soil, compared to the reference (Table 1).

The U-test showed the effect of the grazing technology on the response of the effective index of mobile phosphorus content. In the column with the *p-value* in the table, the significance of the effective index (F) response to the technology by the soil zones takes the *p-value* < 0.05. The exception is the technology of moderate grazing for the third zone. Based on this indicator, a conclusion may be drawn that all technologies in the first, second, and third zones have a significant effect on the content of mobile phosphorus.

The quantitative expression of this effect is determined by the difference between the median for the corresponding technology and the technology without grazing.

On dark chestnut soils of the first zone, the difference between the median values of phosphorus in the case of the technology of weak grazing, compared to that without grazing, was 0.24 mg/100 g, in the case of the technology of moderate grazing, the difference was 0.41 mg/100 g, and in the case of the technology of intensive grazing — 0.61 mg/100 g.

For chestnut soils in the second zone, the difference between the median values of the content of mobile phosphorus in the case of the technology without grazing and that of weak grazing was 0.45 mg/100 g, in the case of the technology without grazing and that of moderate grazing — 0.61 mg/100 g, and in the case of the technology without grazing and that of intensive grazing — 0.69 mg/100 g.

For light chestnut soils in the third zone, the response to the grazing technologies was the

following: weak grazing — 0.1 mg/100 g and intensive grazing — 0.41 mg/100 g, respectively. By the significance level of the *p-value*, the technology of moderate grazing in this sample did not cause a significant response to the quantitative indicator of mobile phosphorus content (F, mg/100 g).

Thus, it was found that the content of mobile phosphorus increased with increasing the intensity of grazing in all types of soil, except for the moderate grazing technology in the third zone of light chestnut soils.

In turn, the deterioration of the physicochemical properties resulted in the increased content of metabolic sodium in the soil, which was an indicator of salinity and increased soil salinization (Nasiev, 2016). In chestnut soils of pastures of the second zone, the content of exchangeable sodium, depending on the grazing technology, increased from 0.08 to 0.32 cmol (equiv.)/kg, compared to the reference. In the soils of the pastures, the content of exchangeable sodium ranged from 4.98 to 5.92 % of the amount of exchange bases, which corresponded to the degree of weak alkalinity. In light chestnut soils in the third zone, with the sum of exchange bases of 15.10 – 15.65 cmol (equiv.)/kg, the content of exchangeable sodium was 1.41 – 1.65 cmol (equiv.)/kg, or 9.33 – 10.54 % of the cationic exchange. By the content of exchangeable sodium, the soil in the pastures with weak and moderate grazing was weakly alkaline, and the soil with intensive grazing was medium alkaline.

In dark chestnut soils, the content of exchangeable sodium, depending on the grazing technology, amounted to 0.36 – 0.61 cmol (equiv.)/kg, or 1.71 – 2.77 % of the total amount of exchangeable bases. By the content of exchangeable sodium, dark chestnut soils in the first pasture zone were non-alkaline (Table 2).

The U-test showed the effect of the grazing technology on the response of the effective index of exchangeable sodium content. In the column with the *p-value* in the table, the significance of the effective index response to the technology by the soil zones takes the *p-value* < 0.05. Therefore, all technologies in the first, the second, and the third zones had a significant effect on the content of exchangeable sodium. The technology in this sample caused a significant response to the quantitative indicator of exchangeable sodium content.

The quantitative expression of this effect was determined by the difference between the median for the corresponding technology and the

technology without grazing.

In terms of the grazing technology on the dark-chestnut soils in the first zone, the difference between the median value of the exchange of sodium in the case of the technology of weak grazing and without grazing was 0.09 cmol (equiv.)/kg, in the case of the technology of moderate grazing and without grazing — 0.29 cmol (equiv.)/kg, and in the case of the technology of intensive grazing and without grazing — 0.33 cmol (equiv.)/kg.

For chestnut soils in the second zone, the difference between the median value for the technology without grazing and weak grazing was 0.09 cmol (equiv.)/kg, for the technology without grazing and that of moderate grazing — 0.29 cmol (equiv.)/kg, and for the technology without grazing and that of intensive grazing — 0.33 cmol (equiv.)/kg.

For light chestnut soils in the third zone, the responses to the grazing technologies were the following: weak grazing — 0.10 cmol (equiv.)/kg, moderate grazing — 0.19 cmol (equiv.)/kg, and intensive grazing — 0.34 cmol (equiv.)/kg.

The tests confirmed the presence of a statistical regularity of increasing the content of exchangeable sodium in all types of soil with increasing the intensity of grazing.

*Agrophysical indicators.* Soil density and structural coefficient are the most important indicators of its fertility. They do not provide the required nutrients to plants, but they can influence their growth and development. Therefore, the knowledge of the soil physical characteristics and the ability to adjust them are required for extended reproduction of soil fertility (Nasiyev, 2014; Blanco *et al.*, 2016; Tesla, 2016).

Assessment of the density and the structural coefficient of chestnut soils in Western Kazakhstan by the main indicators, depending on the grazing technology, showed their sensitivity to trampling. The agrophysical properties of chestnut soils depended on their types and grazing technology. However, with the reduction of loads by the use of weak and moderate grazing technologies, the physical properties of the pastures varied considerably compared to the virgin areas, which could be explained mainly by grass restoration processes in pastures and, therefore, by solid soil phase properties and soil structure stability. Therefore, in the case of weak and moderate grazing, the deterioration of the physicochemical properties of the pasture ecosystems occurred less rapidly than in the case

of intensive grazing (Angassa, 2014; Tesla, 2016).

The analysis of the dynamics of the structural-and-aggregate composition of dark chestnut, chestnut, and light chestnut soils showed certain deterioration in the soil structure under the influence of prolonged pasture use and the pronounced tendency to the restoration that had been observed during the observation period.

Despite the certain deterioration of the structure under the influence of grazing, the soil in the pasture areas with weak and moderate grazing conditions showed good content of agronomically valuable aggregates and structure due to the restoration of vegetation. For instance, on dark chestnut soils with moderate and weak grazing, the soil structure was 63.83 – 71.20 %, with a structural coefficient of 1.80 – 2.48.

On chestnut soils in the case of weak grazing, the soil structure was 65.57 % with the structural coefficient of 2.73, while in the case of moderate grazing, the structure was 65.57 % with the structural coefficient of 1.92.

In the case of moderate grazing, the soil structure of the pastures with light chestnut soils (67.50 %), compared to the structural properties of the soil of the reference plot (75.03 %), reduced by 7.53 %. The structural coefficient of the soil in this pasture plot was 2.10.

In the case of moderate grazing, the structural coefficient of the pastures on light chestnut soils was 1.88, while the soil structure was 64.41 %, which was 10.62 % less than in the reference. In all the soil and climatic zones on the pastures with weak and moderate grazing, the state of the soil structure was "good".

Intensive grazing can change the soil structure (Řeháček *et al.*, 2017). In all the types of chestnut soils with strong grazing, the soil structure reduced to 53.06 – 60.57 % with the structural coefficient of 1.22 – 1.50; the soil structure and the structural coefficient corresponded to "satisfactory" (Table 3).

The U-test showed the effect of the grazing technology on the response of the effective index of agronomically valuable structural aggregates. In the column with the p-value in Table 3, the meaning of the response of the content of agronomically valuable structural aggregates to soil-zone technologies takes a p-value < 0.05. The exception is the technology of weak grazing for the second zone. Based on this indicator, it may be concluded that all the technologies in the first, the second, and the third zones have a significant effect on the content of the agronomically valuable

structural aggregates. The quantitative expression of this effect is determined by the difference between the corresponding technology median and non-grazing technology.

On dark chestnut soils of the first zone, the difference between the median values of structural aggregates in the case of the technology of weak grazing, compared to that without grazing, was 5.6 %, compared to that of moderate grazing — 12.95 %, and compared to that of intensive grazing — 16.89 %.

For chestnut soils in the second zone, the difference between the median values for the technology without grazing and that of moderate grazing was 10.46 %, for the technology without grazing and that of intensive grazing — 21.2 %. The technology of weak grazing in this sample did not cause a significant response in the quantitative indicator of the content of the agronomically valuable structural aggregates.

For light chestnut soils in the third zone, the response to the grazing technologies was the following: weak grazing — 7.53 %, medium grazing — 10.13 %, and intensive grazing — 21.97 %.

Based on the obtained results, it may be concluded that there is a statistical regularity of decreasing the content of agronomically valuable structural aggregates with increasing the grazing intensity for all types of soil, except for the technology of weak grazing in the second zone of chestnut soils.

Another fundamental property of the soil is its density. In contrast to the soil structure, which is a well-known regulator of the physical conditions in it, and has only an indirect effect on plants, the density of the soil directly influences the processes of their life activity (Khadka *et al.*, 2019).

Without knowing the soil density, it is impossible to perform quantitative soil assessment. Therefore, the data about the density of the soil layers and horizons necessarily accompany a full description of the soil profile (Wojciechowski *et al.*, 2020).

Overgrazing may lead to soil degradation and loss of the fertile topsoil, especially in the case of little rainfall and significant evaporation (Khadka *et al.*, 2019). It was confirmed by the results of the research studies. In the third semi-arid zone with an arid climate, the soil in the pastures with intensive grazing in terms of the density degraded to the third degree, the soil density in the 0 – 30 cm soil layer was 1.38 g/cm<sup>3</sup>, or the level of light chestnut soils density under the influence of

grazing was 13.11 %. Such high soil compaction creates anaerobic-like conditions in the root layer and changes the structure of the soil horizons (Tesla, 2016; Lobanov *et al.*, 2020).

The destructive effect of intensive grazing on physical properties, especially on soil density, was reported by many researchers (Nasiyev, 2014; Angassa, 2014; Blanco *et al.*, 2016).

On light chestnut soils in the third zone, the soil density in the reference plot in the 0 – 30 cm horizon was 1.22 g/cm<sup>3</sup>. When grazing was organized following the technology of weak grazing, the density changes in the 0 – 30 cm soil layer were insignificant (1.24 g/cm<sup>3</sup> or soil compaction by 0.02 g/cm<sup>3</sup>). In the case of moderate grazing, slight soil compaction from 1.22 to 1.28 g/cm<sup>3</sup>, or by 4.91 %, was also observed.

The studies also revealed compaction of chestnut and dark chestnut soils in the first and the second zones upon the increased load on the pastures. For instance, in the first dry steppe zone of dark-chestnut soils with intensive grazing, the soil was compacted, compared to the density of the reference plot, by 5.38% (from 1.30 to 1.37 g/cm<sup>3</sup>). In the second zone of arid steppes on chestnut soils, in the case of intensive grazing, the soil density increased from 1.23 g/cm<sup>3</sup> (reference) to 1.30 g/cm<sup>3</sup>, or by 5.69 %. The soil of these zones in the case of intensive grazing degraded to the first degree.

The variation of physical conditions is one of the factors for preserving and maintaining the biodiversity, which is important ecological component of any ecosystem, including the soil one. Assessment of the parameters of linear regression allowed concluding that light chestnut soils had the greatest tendency toward compaction under the influence of grazing. The growth rate in the case of changing the technology was 0.052 g/cm<sup>3</sup>. The degree of degradation was the third one. In this regard, the study was very relevant (Figure 2).

#### 4. CONCLUSIONS:

1. The deterioration of physicochemical indicators, soil degradation, and salinization processes are the most common and significant complications in the management of pasture ecosystems in Western Kazakhstan, requiring for the right decisions due to their environmental impact, as well as reduction of the production rate of safe livestock products.

2. Physicochemical indicators affect the soil quality, which leads to deterioration of the ecological situation in agrocenoses and the

productivity and state of vegetation of pasture ecosystems.

3. Technology of moderate cattle grazing is necessary to solve the problems of qualitative and efficient use of pastures.

4. The main principle of moderate grazing technology implies the use of 65-75% of plants in the grazing season, which, resulting from the vital activity of plants, contributes to the improvement of the physicochemical parameters of soils. This hypothesis is confirmed by the data of standard assessment methods and statistical analysis of physicochemical parameters of chestnut soil types of pasture ecosystems in the territories of three zones of Western Kazakhstan.

5. The idea and research data serve as a prerequisite for the development of conservation measures for the efficient use of pasture ecosystems outside Kazakhstan, in countries and regions with similar pasture management systems.

## 5. ACKNOWLEDGMENTS:

The work was carried out in the Zhangir khan West Kazakhstan Agrarian-Technology University within the framework of program-targeted financing of the Ministry of Agriculture of the Republic of Kazakhstan on the topic BR 06249365 "Creating highly productive pasture lands in the context of North and West Kazakhstan region and the sustainable use thereof".

### RESUMO

O ácido ascórbico, geralmente conhecido como vitamina C, é um ácido fraco e antioxidante natural que exerce funções biológicas importantes na participação da formação do colágeno e na absorção de ferro pelo organismo. O objetivo desse trabalho foi verificar, através da modelagem molecular, cargas parciais e avaliação de parâmetros de reatividade PRM que o mesmo apresenta densidades eletrônicas favoráveis em posições estereoquimicamente localizadas para a formação de sais metálicos associados a pretensos sistemas complexos. Suas propriedades eletrolíticas mostraram um comportamento do tipo 1:1 em solução aquosa milimolar recém-preparada. Isto é concordante com os valores de pH,  $K_{a1}$  e  $K_{a2}$  respectivamente, avaliados para uma situação de equilíbrio através do programa RAÍZES 1.0, desenvolvido pelos autores. A decomposição térmica se inicia em torno de 180 - 190 °C, e segue até atingir a temperatura de 570,3 °C, na qual um pequeno percentual experimental de resíduo foi associado a presença de carbono reduzido. O espectro de absorção na região do infravermelho identificou as principais transições atribuídas a C=O, C-O, C=C, OH presentes em seus grupos funcionais. O espectro de absorção UV-Vis mostrou uma banda intensa que ocorre entre 207 – 312 nm, com pico de absorção máxima,  $A_{m\acute{a}x} = 3,6123$  em 249 e 250 nm. Esta banda se apresenta na região onde ocorrem as transições  $n \rightarrow \pi^*$ ,  $n \rightarrow \sigma^*$  e  $\pi \rightarrow \pi^*$  associada aos grupos cromóforos. A força do oscilador  $f$  é comparável aquelas apresentadas por grupos cromóforos que têm transições moleculares intensas, em que alguns tipos de moléculas são usadas como corantes e outras análogas utilizadas como sensibilizadoras em fotocélulas solares ou dispositivos emissores de radiação eletromagnética.

**Palavras-chave:** Ácido ascórbico, parâmetros de reatividade, força do oscilador, programa RAÍZES.

### ABSTRACT

Ascorbic acid, commonly known as vitamin C, is a weak acid and natural antioxidant that plays essential biological roles in the participation of collagen formation and the absorption of iron by the body. The objective of this work was to verify, through molecular modeling, partial loads and evaluation of PRM reactivity parameters, that it presents favorable electronic densities in stereochemically located positions, for the formation of metallic salts, associated with supposed complex systems. Its electrolytic properties showed a type 1: 1 behavior in freshly prepared aqueous millimolar solution. This is in agreement with the values of pH,  $K_{a1}$  and  $K_{a2}$  respectively, evaluated for an equilibrium situation through the program RAÍZES 1.0, developed by the authors. Thermal decomposition starts around 180-190°C and continues until reaching a temperature of 570.3 °C, in which a small experimental percentage of waste has been associated with the presence of reduced carbon. The absorption spectrum in the infrared region identified the main transitions attributed to C = O, C = C, OH, present in their functional groups. The UV-Vis absorption spectrum showed an intense band that occurs between 207 - 312 nm, with maximum absorption peak,  $A_{max} = 3,6123$  at 249, and 250 nm. This band presents itself in the region where the  $n \rightarrow \pi^*$ ,  $n \rightarrow \sigma^*$  e  $\pi \rightarrow \pi^*$  transitions occur associated with the chromophore groups. The strength of the oscillator is comparable to those presented by chromophore groups that have intense molecular transitions, in which some types of molecules are used as dyes and other analogs used as sensitizers in solar photocells or devices emitting electromagnetic radiation.

**Keywords:** Ascorbic acid, reactivity parameters, oscillator strength, RAÍZES program.

## 1. INTRODUÇÃO:

O ácido ascórbico ( $C_6H_8O_6$ ), denominado comumente de vitamina C, é um ácido fraco e antioxidante natural que exerce funções biológicas importantes na participação da formação do colágeno e na absorção de ferro pelo organismo (ARRIGONI and TULLIO, 2002; LYKKESFELDT and TVEDEN-NYBORG 2019). Além disso, sua ação antioxidante atribui capacidade de aumentar o tempo de conservação dos alimentos (BAUERNEFEIND and PINKERT, 1970). Foi observado neste trabalho que o mesmo apresenta densidades eletrônicas favoráveis para a formação de sais metálicos, precursores de pretensos sistemas complexos, atribuindo a esta substância outras aplicações também relevantes na ciência. Em sua estrutura há 4 grupos  $-OH$ , um oxigênio ligado internamente a um grupo de cinco átomos de carbono, e outro oxigênio periférico mais externo com uma dupla ligação, apresentando assim boa solubilidade em água, devido à formação de ligações de H. Possui ponto de fusão em torno de 190-192 °C, donde a partir daí se decompõe por aquecimento. Na presença da luz, oxigênio, em solução aquosa e sensibilizadores, sofre oxidação aos ácidos desidroascórbico e dicetogulônico, onde este último não apresenta mais nenhuma atividade do composto (TAVARES *et al.*, 2003; ZENG, 2005). Possui dois hidrogênios ionizáveis com  $pK_{a1} = 4,17$  e  $pK_{a2} = 11,2$  (BOBBIO and BOBBIO, 1995), porém tem-se observado na literatura, compostos de ascorbato monovalentes de sódio, lítio, magnésio e cálcio (KOZIOL *et al.*, 1992).

O ácido ascórbico forma também complexos com íons metálicos do tipo MA e MHA (M = metal, A = ascorbato, HA ácido ascórbico), dependendo do pH do meio, mas esses complexos são relativamente instáveis (FORNARO and COICHEV, 1997). Dados da literatura têm sugerido que para complexos formados com uma variedade de cátions divalentes como  $Ca^{2+}$ ,  $VO^{2+}$ ,  $Mn^{2+}$ ,  $Zn^{2+}$  e  $Cd^{2+}$ , o ácido ascórbico atua como ligante monodentado. Estudos de RMN de  $C^{13}$  levaram à conclusão de que para os íons metálicos  $Co^{2+}$ ,  $Fe^{2+}$  e  $Mn^{2+}$ , em pH 8,5, os complexos ascorbato-íon metálico são formados por quelação através dos átomos O5 e O6 na modelagem molecular realizada para este trabalho mostrada na Figura 1A para o ácido ascórbico e pelos átomos O-2 e O-3 na perspectiva proposta por KOZIOL e colaboradores (KOZIOL *et al.*, 1992), para o ânion ascorbato mostrado na Figura 1B. Estudos similares com  $Ni^{2+}$  em presença de ácido

ascórbico mostraram que o ascorbato também está ligado ao íon metálico pelos oxigênios, e a exemplo destes tem-se o Ferro(III)-ácido ascórbico e o cis-1,2-diaminociclohexano-platina(II)/ácido ascórbico, sendo que para este último, a Pt se coordena pelo O2 e C5 na modelagem molecular (Figura 1A) e pelos átomos O-5 e pelo C-2 na estrutura do íon (Figura 1B), segundo a literatura (FORNARO and COICHEV, 1997). Outros complexos envolvendo a Pt também corroboram a complexação através da Pt-C e Pt-O (YUGE *et al.*, 2002). A Figura 02 A, mostra a modelagem molecular para o ácido ascórbico, nuvem de potencial coulômbico, distância de ligação, ângulos de ligação e cargas parciais e a Figura 02 B, ilustra a comparação de algumas propriedades da modelagem do ácido ascórbico e do íon ascorbato segundo o programa WebLab (WEBLAB, 1998).

Poucos trabalhos foram encontrados na literatura sobre a determinação das estruturas de complexos estáveis em solução entre o ascorbato e íons metálicos. No entanto, muitos estudos comprovam a formação de complexos como espécies intermediárias durante as reações de oxidação do ácido ascórbico por íons metálicos (FORNARO and COICHEV, 1997).

O objetivo desse trabalho foi contribuir com informações adicionais desta espécie na formação de sistemas complexos, abordando propriedades estruturais, parâmetros de reatividade, estabilidade térmica, eletrônicas e espectrais do ácido ascórbico e o íon ascorbato livre e em solução.

## 2. DESENVOLVIMENTO:

A modelagem molecular foi realizada através do programa WebLab ViewerPro para os estudos preliminares de parâmetros de reatividade moleculares PRM's, seguindo metodologia proposta pela literatura (GEORGE, 1971; CHANDRA, 1981; WEBLAB, 1998; LIMA *et al.*, 2007, 2019; COSTA *et al.*, 2015). Os valores de cargas parciais foram obtidos através do programa WebLab-Viewer Pro© (WEBLAB, 1998) e os parâmetros de reatividade PRM calculados através da equação 01.

$$\Re = \frac{\int qid\tau}{\sum |\int qid\tau|} \quad (\text{Eq.01})$$

A Figura 2A e Tabela 1 mostram a modelagem, alguns parâmetros estruturais, ângulos e distâncias de ligação, cargas parciais e

os parâmetros de reatividades moleculares PRM's, calculados para o ácido ascórbico. A Figura 2B mostra a comparação de algumas propriedades da modelagem entre o ácido ascórbico e o íon ascorbato, pelo uso do programa WebLab (WEBLAB, 1998).

Nas práticas experimentais, foi utilizado o ácido ascórbico PA comercial de marca CRQ pureza 99,0 % para obter as medidas de pH e estudos do equilíbrio, medidas das condutividades molares, análise térmica, caracterização dos espectros infravermelhos e estudos dos espectros uv-vis do estado sólido e das soluções respectivamente.

Medidas de pH foram realizadas em diferentes concentrações em um pHmetro TECNOPON mPA-210 de precisão  $\pm 0,005$ , em temperatura ambiente de  $25 \pm 1$  °C. Também foi usado o programa RAÍZES 1.0 em linguagem QBASIC, elaborado com o propósito de avaliar o equilíbrio, e calcular as concentrações de  $H^+$  e valores de pH, para verificar a concordância teórico-experimental dos resultados deste trabalho (LIMA *et al.*, 2017, 2019; PERRIN, 1974; PRICHARD, 2003; VALCÁRCEL, 2000; VOGEL'S 1996). A Tabela 02 mostram os cálculos para  $[H^+]$  e pH teóricos em solução aquosa obtidos pelo programa RAÍZES 1.0 e as medidas de pH experimentais.

A condutividade foi medida através de um condutímetro MS-TECNPON mCa-150, com precisão  $\pm 0,001 \mu S cm^{-1}$ . O propósito de uso desta técnica é avaliar a condutância das amostras preparadas e observar o tipo de eletrólito da espécie molecular, com a expectativa de correlacionar com a condutividade repassada aos seus produtos derivados e a sua capacidade como íon livre coordenante (ANDJELKOVIÆ *et al.*, 2001; CHANDRAMOHAN and CHANDRALEKA, 2014; COSTA, *et al.*, 2013; GEARY, 1971; MELO *et al.*, 2009; SCHOLZ, 2010; SOUSA *et al.*, 2018; WANG, 2000). Os valores de condutividade molar foram calculados a partir da equação 02

$$\Lambda_M = (k_{sol} - k_{solv}) \cdot 10^3 / M \quad (Eq\ 02),$$

conforme suportado pela literatura pesquisada (COSTA, *et al.*, 2013; GEARY, 1971; GUTTMAN, 1976; LIMA, *et al.*, 2016).

A Tabela 3 mostra os dados e condições das soluções avaliadas, a condutividade  $k$  e a condutividade molar  $\Lambda_M$ .

A análise térmica foi realizada através de um equipamento TA Instruments, modelo SDTQ600. Os ensaios foram realizados em

cadinho de platina sob atmosfera de ar sintético com vazão do gás de purga 100 mL/min e razão de aquecimento de 10 °C/min iniciando em temperatura ambiente de 24 °C até 900 °C, com massa de amostra de 10,3 mg. A Figura 3 ilustra as curvas TG e DTG do ácido ascórbico e a Tabela 4 ilustra uma proposta para a decomposição térmica (ANDJELKOVIÆ *et al.*, 2001; CHANDRAMOHAN and CHANDRALEKA, 2014; OLIVEIRA *et al.*, 2011; SEIF *et al.*, 2020).

O espectro de absorção na região do infravermelho foi registrado em um espectrofotômetro com transformada de Fourier, modelo IR Affinity-1 da Shimadzu, utilizando amostras sólidas em pastilhas de KBr e as transições foram atribuídas para os grupos funcionais mais importantes (BUENO, 1980; HUHEY, 1983; COTTON, F. A. and WILKINSON, 1988; NAKAMOTO, 1978; SILVEIRA, 2018; SÓCRATES, 1980; THOMPSON, 1979). A Figura 4 mostra o espectro obtido e a Tabela 5 contém as atribuições experimentais.

Espectros uv-vis foram registrados em solução aquosa pelo uso de um equipamento UV-VIS SHIMADZU 1650 PC no intervalo de 190 – 900 nm, com precisão de absorbância de  $\pm 0,002$  e comprimento de onda  $\pm 0,1$  nm. As medidas foram obtidas em temperatura ambiente de  $25 \pm 1$  °C. A Figura 05 ilustra transições generalizadas entre estados eletrônicos moleculares, atribuições de transições, e o espectro uv-vis do HAsc  $5,00 \times 10^{-4}$  mol/L em solução aquosa completo 190 – 1000 nm e da área de interesse 190 – 350 nm. Na Tabela 06 estão os parâmetros espectrais uv-vis para o espectro obtido do HAsc.

A Tabela 6 contém os cálculos obtidos a partir dos dados espectrais. Foram utilizados os métodos citados na literatura para o cálculo da área sob a curva do espectro de absorção e a força do oscilador  $f$  (DRAGO, 1965; FIGGIS, 1966; LIMA *et al.*, 2014, 2018),

$$\text{Drago: } f = 4,6 \times 10^{-9} \cdot \int \epsilon_{(\sigma)} d\sigma \quad (Eq.03)$$

$$\text{Figgs: } f = 4,32 \times 10^{-9} \cdot \int \epsilon_{(\sigma)} d\sigma \quad (Eq\ 04)$$

Na qual a integral  $\int \epsilon_{(\sigma)} d\sigma$  corresponde a área sob a curva de absorção, e neste trabalho foi obtida pela aproximação da gaussiana através da avaliação da meia-banda,

$$\epsilon_{\text{máx}} \cdot (1/\lambda_1 - 1/\lambda_2) \quad (Eq.05)$$

### 3. RESULTADOS E DISCUSSÕES:

Através da modelagem molecular foi possível avaliar que o ascorbato possui

parâmetros de reatividade compatíveis e densidades eletrônicas favoráveis, localizadas em grupos de átomos doadores de elétrons, imprescindíveis para a formação de sistemas complexos, podendo se comportar como um versátil agente quelante na química de coordenação, como já observado em alguns compostos (KOZIOL, *et al.*, 1992; YUGE, *et al.*, 2002). As cargas parciais situadas nos átomos de maiores relevâncias se encontram no O1 (-0,3935), O2 (-0,3875) e O6 (-0,3597), (Figuras 1A, 2A, 2B e Tabela 01) podendo, inclusive ocorrer situações em que átomos de carbono formam ligações com algum centro metálico de natureza ácido mole, a exemplo da Pt no complexo cis-1,2-diaminociclohexano-platina(II)/ácido ascórbico, que se coordena pelo O(5) e pelo C(2) na estrutura do íon ascorbato da Figura 01 II e na modelagem molecular na Figura 01 I, pelo O2 (-0,3875) e C5 (+0,1738) segundo a literatura (FORNARO and COICHEV, 1997; YUGE, *et al.*, 2002). Acredita-se que a ligação entre O-Pt-C neste complexo, que ocorre através de densidades negativas e positivas, se dá por um mecanismo de transferência de elétrons (de densidade eletrônica), na qual a Pt recebe em alguma magnitude densidade eletrônica pelo átomo de oxigênio e doa, também parcialmente, densidade eletrônica para o átomo de carbono, em um tipo de retrodoação envolvendo orbitais  $\sigma$  e  $\pi$ .

As medidas de condutância realizadas indicam que o comportamento eletrolítico empírico da amostra é do tipo 1:1 em solução aquosa milimolar recém-preparada, o que é totalmente concordante com os valores de pH,  $K_{a1}$  e  $K_{a2}$  respectivamente, mesmo possuindo 4 grupos -OH e dois hidrogênios ionizáveis conforme mostrado na Figura 1 e Tabelas 2 e 3.

Observou-se que na análise térmica do ácido ascórbico, a decomposição se inicia em torno de 180 - 190 °C, sendo concordante com a literatura (REDA, 2011) e segue até atingir a temperatura de 570,3 °C, na qual o percentual experimental do resíduo, que foi associado a presença de carbono reduzido, atingiu 1,3615 % da amostra inicial. Em comparação com o calculado teoricamente de 1,364 %, verifica-se que está em boa concordância com o que foi proposto estequiometricamente para a decomposição completa da amostra, conforme a reação:

mostrado na Figura 3 e Tabela 4.

O espectro de absorção na região do infravermelho mostra as bandas principais proporcionadas pelos grupos funcionais da molécula, tais como: estiramentos C=O da lactona (1760  $\text{cm}^{-1}$ ), C-O (1109, 1110, 1134, 1195  $\text{cm}^{-1}$ ), C=C (1668  $\text{cm}^{-1}$ ), e bandas OH (3217, 3309, 3404, 3533  $\text{cm}^{-1}$ ) segundo a literatura (SILVEIRA, 2018; SOUZA *et al.*, 2015; UNARELOGLU, *et al.*, 2002). A Figura 04 e Tabela 5 mostram as atribuições especificadas. Estas transições serão de grande valia na constatação de evidências de formação de ligações químicas em sistemas complexos (BUENO, 1980; COTTON, F. A. and WILKINSON, 1988; HUHEY, 1983; NAKAMOTO, 1978; SILVEIRA, 2018; SÓCRATES, 1980; SOUZA *et al.*, 2015; THOMPSON, 1979; UNARELOGLU, *et al.*, 2002).

O espectro de absorção UV-Vis do HAsc em solução aquosa  $5 \times 10^{-4}$  mol/L recém-preparada, mostrou uma banda intensa que ocorre entre 207 - 312 nm, com pico de absorção máxima,  $A_{\text{máx}} = 3,6123$ , em 249 e 250 nm. Esta banda se apresenta na região onde ocorrem as transições  $n \rightarrow \pi^*$ ,  $n \rightarrow \sigma^*$  e  $\pi \rightarrow \pi^*$  (ASSIS, 2013; ATKINS, 1991; PAVIA, 2010; SKOOG, 2002), associada aos cromóforos C=C-C=O (220-315 nm), C=O (150-250 nm) e C=C (200-700 nm), também presentes em moléculas similares. A Figura 05 ilustra o mecanismo de absorção de fótons, atribuições de transições e o espectro UV-Vis para a solução aquosa do ácido ascórbico. A Tabela 06 contém os parâmetros espectrais calculados, conforme a literatura (LIMA *et al.*, 2014).

#### 4. CONCLUSÕES:

Através da modelagem molecular foi possível avaliar que o íon ascorbato possui parâmetros de reatividade compatíveis e densidades eletrônicas favoráveis, localizadas em grupos de átomos doadores de elétrons, para a formação de sistemas complexos, podendo se comportar como um versátil agente quelante na química de coordenação. As cargas parciais de densidade negativa de maiores relevâncias estão situadas nos átomos O1 (-0,3935), O2 (-0,3875) e O6 (-0,3597), (ver modelagem na Figura 1 I e Tabela 1). Ainda assim, a possibilidade de interações com moléculas de água, através de ligações de hidrogênio, favorece a uma grande solubilidade em água e podem inviabilizar algumas dessas possibilidades de ligações com cátions metálicos, dependendo do meio

reacional, além de ser possível, dependendo da reatividade do cátion metálico, reações que formem outros derivados como subprodutos oriundos de sucessivas etapas de oxidação do ácido ascórbico e do ascorbato.

O comportamento eletrolítico empírico do ácido ascórbico é do tipo 1:1 em solução aquosa milimolar (CHANDRAMOHAN and CHANDRALEKA, 2014; GEARY, 1971; GUTTMAN, 1976), o que é totalmente concordante com os valores de pH,  $K_{a1}$  e  $K_{a2}$  calculados e experimentalmente confirmados, mesmo possuindo 4 grupos -OH e dois hidrogênios ionizáveis.

Observou-se que na análise térmica do ácido ascórbico, ao atingir a temperatura de 570,3 °C o percentual de carbono residual experimental chegou a 1,3615 %, que em comparação ao teórico, está de acordo com o estabelecido estequiometricamente.

O espectro na região do IV do ácido ascórbico mostra as bandas principais proporcionadas pelos grupos funcionais da molécula, tais como os estiramentos C=O lactona (1760  $\text{cm}^{-1}$ ), C=C (1668  $\text{cm}^{-1}$ ), C-O (1109, 1110, 1134, 1195  $\text{cm}^{-1}$ ), O-H (3217, 3309, 3404, 3533  $\text{cm}^{-1}$ ), segundo a literatura (SILVEIRA, 2018; SOUZA *et al.*, 2015; UNARELOGLU, *et al.*, 2002), característicos para atribuições de formação de ligações envolvendo estes grupos em particular (BUENO, 1980; NAKAMOTO, 1978; SÓCRATES, 1980).

Os espectros UV-Vis revelaram uma banda de absorção entre 207-312 nm, com um pico em 249 nm de  $\epsilon_{\text{máx}} = 7,225 \times 10^3 \text{ L mol}^{-1} \text{ cm}^{-1}$ , atribuída às transições moleculares  $n \rightarrow \sigma^*$ ;  $\pi \rightarrow \pi^*$  e  $n \rightarrow \pi^*$ , referente a presença dos cromóforos C=O, C=C e O=C-C=C presentes na molécula. A força do oscilador  $f$  é comparável, aquelas apresentadas por grupos cromóforos em transições moleculares, em que alguns tipos de moléculas usadas como corantes e outras análogas usadas como sensibilizadoras de fotocélulas solares, apresentam valores da ordem de  $10^{-1} - 1$ , o que reforça a potencialidade de aplicação destes sistemas em dispositivos bombeadores de elétrons em sistemas químicos complexos (COTTON and WILKINSON, 1988; HUHEY, 1983; SHRIVER *et al.*, 1994; THOMPSON, 1979), e emissores de radiação e/ou de elétrons.

## 5. AGRADECIMENTOS:

Os autores agradecem ao IQ da UFRN,

pelo registro das curvas de análise térmica TG e DTG, e pelos espectros na região do Infravermelho e Uv-Visível. Também agradecem ao aluno de IC do IQ-UFRN Lucas da Silva Araújo pelas contribuições pontuais neste trabalho.

(\*) Valores de  $\Delta$  interpretados para cada átomo como:

$\delta_2 - \delta_1$ ;  $\Delta < 0$  aumento relativo de densidade de carga negativa e  $\Delta > 0$  aumento relativo de densidade de carga positiva.

$\mathfrak{R}_2 - \mathfrak{R}_1$ ;  $\Delta < 0$  aumento relativo de parâmetro de carga negativa e  $\Delta > 0$  aumento relativo de parâmetro de carga positiva.

Obs. Os valores de  $\Delta$  não devem ser interpretados como valores absolutos, mas como valores relativos para comparação superficial de resultados.

**Tabela 2.** Cálculos para  $[H^+]$  e pH em solução aquosa ( $pH_{\text{água}} = 6,80$ ), usando o programa “RAIZES”, para o ácido ascórbico de  $Ka_1 = 6,76 \times 10^{-5}$  em temperatura ambiente de  $25 \pm 1$  °C.

**RESUMO**

A química é uma das disciplinas científicas consideradas difíceis para a compreensão dos seus conceitos microscópicos e macroscópicos por parte dos alunos. Os estudantes também afirmam que esta disciplina é tediosa e complicada. Eles são incapazes de conectar o que é mostrado na estrutura visual ao processo e fenômeno. No contexto da automotivação dos estudantes universitários, há mais chances de expandir a estimulação da aprendizagem. Este estudo teve como objetivo melhorar a autoconfiança e o domínio de conceitos dos estudantes de ensino de química usando a aprendizagem baseada em problemas. Foi utilizado o método quase-experimental com o design do grupo de controle pré-teste-pós-teste não equivalente. A população incluiu todos os alunos da aula de eletroquímica da Universidade Lampung em 2019. A técnica de amostragem proposital empregada dividiu a amostra em dois grupos. O primeiro grupo foi chamado Classe A e foi considerado como a classe experimental - usando aprendizado baseado em problemas -. O segundo grupo, Classe B, foi considerado como a classe de controle - usando o modelo convencional em que o professor aplicava o método de fala na entrega dos materiais durante a aula -. A autoconfiança e o domínio de conceitos da classe A têm um valor n-Gain maior que a classe B e o resultado do tamanho do efeito é que a classe B tem um efeito maior que a classe A. Com base no resultado, pode-se concluir que a aprendizagem baseada em problemas tem um grande influência na melhoria da autoconfiança e do domínio de conceitos sobre o tema eletroquímico.

**Palavras-chave:** *aprendizagem baseada em problemas, autoconfiança, domínio de conceitos e eletroquímica*

**ABSTRACT**

Chemistry is one of the scientific disciplines considered difficult for students to understand its microscopic and macroscopic concepts. Students also claim that this discipline is tedious and complicated. They are unable to connect what is shown in the visual structure to the process and phenomenon. In the context of self-motivation among university students, there is a higher chance of expanding the stimulation of learning. This study aimed to improve self-confidence and the mastery of concepts of chemistry teaching students using problem-based learning. The quasi-experimental method was used with the design of the non-equivalent pre-test-post-test control group. The population included all students in the electrochemistry class at Lampung University in 2019. The purposeful sampling technique employed divided the sample into two groups. The first group was called Class A and was considered as the experimental class - using problem-based learning -. The second group, Class B, was recognized as the control class - using the conventional model in which the teacher applied the speech method in the delivery of materials during the class -. Class A's self-confidence and mastery of concepts have a higher n-Gain value than class B, and the result of the effect size is that class B has a more significant effect than class A. Based on the outcome, one can conclude that problem-based learning has a significant influence on improving self-confidence and mastery of concepts on the electrochemical theme.

**Keywords:** problem-based learning, self-confidence, concept mastering, and electrochemistry.

## 1. INTRODUCTION:

Either teachers or lecturers must develop their competence in teaching. Chemistry lesson needs experiences (Toshio, 2015; Ezazi and Nourian, 2016). A study has shown that students have difficulty experienced in solving a problem relating to the ability to visualize the structure and the processes that happened at a minimal level and relating between the phenomenons in chemistry at another level (Sunyono and Sudjarwo, 2018). Chemistry commonly refers to failure, boring, and the reluctance of most students (Nurhadi, 2004; Ayyildiz, and Tarhan, 2018). The condition can cause students hard to catch up with the materials given (Keller, 2016). The factor that causes the problems in chemistry is namely models, methods, and strategies that are not precisely used or not optimum used and the chemistry lesson itself.

Chemistry is a branch of science that involves either microscopic or macroscopic concepts, which cause students hard to understand and reluctant to continue their studies in chemistry (Sirhan, 2007). The ability to understand the idea must be improved moreover. (Sunyono and Meristin, 2018) shown that chemistry lesson must be guided to increase the student multi-representation both verbally and visually in order their ability to associate the chemistry phenomenon can be improved. Commonly students experience difficulty understanding the concept are namely misconception, incapable of interpreting information to relate to the chemistry topic given (Michaliskova and Proksa, 2018). More explained explicitly by (Tamani *et al.*, 2015) that senior high school students do not have ideas and contact related to the thermodynamics concept.

The understanding of students' learning can help the teacher to manage strategies in teaching. A correct learning model applying is needed to solve the problems. Other researchers used problem-based learning (PBL) to solve chemistry problems are (Maysara, 2016; Ayyildiz, and Tarhan, 2017; Acar-sesen and Tarhan, 2013). The Basic concept of PBL model is to provide the basic concepts, instructions, references, or links and skills needed in the learning where the teacher becomes facilitator (Leou, Abder, Riordan, and Zoller, 2006; Yazar Soyadı, 2015). This is intended so that students enter the learning atmosphere more quickly and get an accurate 'map' of the direction and purpose of learning (Pratiwi, Cari, Aminah, and Affandy, 2019; Rani, 2018; Rudibayani, 2018). Furthermore, this is needed to

ensure students get the primary key learning material, so there is no possibility of being missed by students as can happen if students learn independently. The concepts given need not be detailed, preferably in the form of outlines so that students can develop them independently in-depth (Nagarajan and Overton, 2019; Pratiwi *et al.*, 2019). Problem-based learning is recently used widely and improved because this model has an underlying assumption that the students can solve the problems in their daily life so that the students have learned (Marra *et al.*, 2014).

The problem-based learning model is a learning model that presents contextual problems that stimulate students to learn. In classes that apply problem-based learning, students work in teams to solve real-world problems (Isaksen and Lauer, 1998; Madhuri, Kantamreddi, and Prakash Goteti, 2012; Raiyn and Tilchin, 2015). In this model, the students will be faced with the daily problems that relate to the topic given to activate the prior knowledge, and then the experience will be brought in collaboration in a small group to discuss the problem given (Affandy, Aminah, and Supriyanto, 2019; Pratiwi *et al.*, 2019; Raiyn and Tilchin, 2015).

Schmidt *et al.*, (2011) shown something to be concerned about the problem given, it must: 1) Authentic 2) Adapted from prior knowledge 3) involve the students in discussion 4) guided to learning issues identification 5) stimulate self-directed learning (SDL) and 6) attractive. The effect of applying PBL with the pre-test/post-test method in learning compared to the conventional method in engineering students can increase the achievement (Yadev *et al.*, 2011).

In the PBL, the teacher gives the instructions then the student constructs their knowledge independently based on the guidance from the teacher. A teacher is a good facilitator in involving the students in collaboration, discussion, communication, and training their logic and critical thinking. The teacher that applied PBL helps the students to develop their ability that needed in daily life activities are namely cooperative, analysis, communicative, researching, synthesis, and problem solving (Abanikannda, 2016).

With PBL meaningful learning will occur. Students who learn to solve a problem will apply the knowledge they have or try to find out the knowledge needed (Isaksen and Lauer, 1998; Yazar Soyadı, 2015). Learning can be more meaningful and can be expanded when students are dealing with situations where the concept is applied (Isaksen and Lauer, 1998; Rosidin,

Maskur, Kadaritna, and Saputra, 2019). Besides the cognitive aspect, namely the ability to mastering the concept, the affective aspect also needs to be concerned in chemistry learning. One of the characters is self-confidence. Self-confidence is the positive attitude of an individual in developing good values for both the environment and themselves. (Schmude, Serow, and Tobias, 2011). There is no study related to problem-based learning model and self-confidence in chemistry learning at school. The students in their studies need confidence.

Self-confidence can improve the achievement of the student academically in the cognitive test (Kleitman and Stankov, 2005). A class that has a diversity of student input will give pressure on their self-development. Moreover, self-confidence can be influenced by gender, just like showed in the study of Federicova *et al*, (2018). Self-efficacy became a part of the self-esteem of a person. Around 46.82% of Mulawarman students showed self-efficacy to pass organic chemistry (Erika, 2017). The data of the Program for International Student Assessment (PISA) has shown that self- efficacy of the student affects their achievement both in academics and their attitude. To practice and improve the self-confidence of the students, the specific learning model is needed (Erika, 2017).

The proposed problem statement in this study is that "How does the application of PBL model improve the self-confidence and concept mastery of the student?"

Therefore, this study aimed to evaluate the effect of applying PBL model to the self-confidence and the concept mastery of the student in electrochemistry material at the university level.

## 2. MATERIALS AND METHODS:

The research method is quasi-experimental with a non-equivalent pretest-posttest control group design (Fraenkel, 2012; Sugiyono, 2013) to compare the PBL model and the conventional model. The design is shown in Table 1.

**Table 1.** Research design (Fraenkel, 2012; Sugiyono, 2013)

| Class        | Treatment      |   |                |
|--------------|----------------|---|----------------|
| Experimental | O <sub>1</sub> | X | O <sub>2</sub> |
| Control      | O <sub>1</sub> | - | O <sub>2</sub> |

Note: O<sub>1</sub> is pre-test; X is the PBL model, and O<sub>2</sub> is the post-test.

The participants who took part in the research consisted of 50 students in total for both classes (experiment and control class). Regarding the gender, it covers 30 female and 20 male students by age ranging from 20 to 21 years old. They sat in the first semester from the running academic year of 2019/ 2020 in their university calendar. There was no special exclusion or inclusion applied as the sample intended supposed to be diverse from age, gender, and character background. They had declared their agreement about to involve in the data collection from their responses to be used for scientific purposes without any term and conditions apply. They were two classes taken covering class A as the experimental that used a problem-based learning model and class B as the control group that used the conventional model. The random sampling was used as a sampling technique. The dependent variable in this research is the PBL model; the independent variable is self-confidence and concept mastery, while the control variable is the electrochemistry topic.

The type of data in this research was test result data of pre-test and post-test on concept mastery and self- confidence, the questionnaires of self-confidence, and also observation result of teaching-learning activity as the primary data. This research was used instruments to collect the data. Tools used in this research were pre-test and post-test questions about concept mastery that consist of 5 essay questions and 10 on questionnaires about self-confidence that comprised of 15 statements as described in Appendix 1 and 2. Besides that, there was an assignment paper, namely an observation sheet of PBL activity.

The validity and reliability of the instrument were analyzed with SPSS v.22 for windows software. The question validity was determined by comparing the r-table value (the fixed score of data showing the effectiveness) with the r-calculate value (the gained score data processing to see the significance) spreading by the range scale score is 1-100. The criteria are if the rtable < rcalculate then the question is valid. Cronbach's Alpha determined the reliability with the requirements of reliability degree (Arikunto, 2013; Istiyono, Mardapi, and Suparno, 2014; Mardapi, 2012).

The next is to know that the result applies to the population so that the t-test was conducted. Before it, the normality and homogeneity test was done to the pre-test and post-test results and the value of n-gain using SPSS v.22 for windows software. The normality test was determined by

the value of significance (Sig). In the Shapiro-Walk column. In contrast, the homogeneity test was established by the value of sig. in the Test of Homogeneity of Variance Column.

### 3. RESULTS AND DISCUSSION:

#### 3.1. Validity and Reliability

The result of the self-confidence instrument test is shown in Table 2 and Table 3 for the mastery concept. Based on Tables 2 and 3, all questions are valid. The result calculation of the instrument reliability test showed based on the value of Cronbach's Alpha is 0.904 for mastery concept and 0.958 for self-confidence, which means the instrument test has high criteria of reliability, so the test was stated valid and reliable.

#### 3.2. The result of Pre-test and Post-test

The average of pre-test and post-test value of mastery concept of the student is shown in Figure 1. Based on Figure 1, the average pre-test value of the control class is 47.29, and the experimental class is 35.00. While for the average post-test value of the control class is 71.97 and the experimental class is 80.45. It showed that the value of the experimental class was more significant than the control class.

The averages value of self-confidence can be seen in Figure 2. As shown in Figure 2, the average initial value of the control class is 63.45, and the experimental class is 63.14, while after treatment, the value of the control class is 73.31 and the experimental class is 83.88. It showed that the value of self-confidence in the experimental class is greater than the control class.

Then the result of the n-gain value of concept mastery and self-confidence was observed. All the data processing result were generated for all aspects by considering the n-Gain value for the self-confidence form initial and final ability. The n-Gain value for concept mastery was generated from pre-test and post-test that was tested to the experimental class using PBL model and the control class using conventional one.

The result of the data processing result was shown in Figure 3. Based on Figure 3, the average n-gain value of self-confidence in the experimental class is 0.53 with the "medium" criteria, and the control class is 0.26 with "low" criteria. While the average n-gain value of concept mastery in the experimental class is 0.71 with "high" criteria, and the control class is 0.29 with

"low" criteria. It showed that the average n-gain value in the experimental class has greater than the control class. The difference of n-gain caused by the treatment, the PBL model in the experimental class and the conventional model in the control class.

#### 3.3. The result of normality and homogeneity test

Based on the normality test of self-confidence n-gain value in the experimental class known that the significant value is 0.311 is greater than 0.05 so can be concluded that the hypothesis where PBL contributed positively to the students understanding on chemistry concept was accepted or the data comes from the normally distributed population. Then, the significant value for self-confidence n-gain of the control class was 0.069 has greater than 0.05, so it means the hypothesis H0 was accepted or H1 was rejected, or the data comes from the normally distributed population. The normality test of concept mastery n-gain value in the experimental class has a significant value 0.754, while for the control class is 0.379, both of them were greater than 0.05, so the hypothesis H0 was accepted or H1 was rejected, or the data comes from the normally distributed population.

The sig obtained the homogeneity test of self-confidence n-gain value is 0.080, and for the concept, mastery is 0.271. The result showed that significant value is higher than 0.05 it means H0 was accepted or the variance of the population was homogenous.

#### 3.4. The result of Independent Sample T-Test

The result of two average difference tests for self-confidence showed in Table 4, while the concept mastery aspect showed in Table 5.

**Table 4.** Independent sample t-test self-confidence test value

| Class        | The average value of n-Gain | p sig (2-tiled) |
|--------------|-----------------------------|-----------------|
| Experimental | 0.53                        | 0.000           |
| Control      | 0.26                        |                 |

Both the result was showed that the sig 2-tailed value is  $0.000 < 0.05$ ; it means that H0 was rejected, and H1 was accepted, or the average of n-gain in both aspects was higher in the experimental class with the PBL model than the control class with the conventional model. Hermawati stated that the concept of mastery of learning would be better if there were optimum

students' involvement in the learning process (Hermawati, 2012). Fuaidah (2017) showed the contextual approach-based worksheet could improve the self-confidence of the student in mathematics learning.

**Table 5.** Independent sample t-test value

| Class        | The average value of n- | p sig (2-tiled) |
|--------------|-------------------------|-----------------|
| Experimental | 0.71                    | 0,000           |
| Control      | 0.31                    |                 |

### 3.5. The calculation result of Effect Size

After the t-test of pre-test and post-test in both aspects self-confidence and concept mastery, then the value of tcalculate was used to calculate the effect size. The result of self-confidence showed in Table 6 and the concept mastery showed in Table 7.

**Table 6.** Self-confidence Effect size Value

| Class        | T <sub>count</sub> | Effect size | Criteria |
|--------------|--------------------|-------------|----------|
| Experimental | -17.31             | 0.81        | Large    |
| Control      | -10.73             | 0.63        | Medium   |

**Table 7.** Concept mastery Effect size Value

| Class        | T <sub>count</sub> | Efeect size | Criteria |
|--------------|--------------------|-------------|----------|
| Experimental | -21.634            | 0.87        | Large    |
| Control      | -10.189            | 0.60        | Medium   |

### 3.5. Implementation of the PBL model

The result in the experimental class showed in following Table 8.

**Table 8.** Implementation of the PBL model

| Meeting | %     | The average | Criteria  |
|---------|-------|-------------|-----------|
| 1       | 75.00 | 85.87       | Very high |
| 2       | 89.58 |             |           |
| 3       | 93.05 |             |           |

According to Table 8, the average value of the PBL model implementation in the experimental class increased from the first meeting to the third meeting, and it has "very high" criteria. These criteria showed that the learning activity ran well. The aspect that assigned in the implementation occupied the learning enthusiasm, student activity,

team-work, and the last was the result.

The analysis result of the PBL model implementation with very high achievement showed that the student improved in the experimental class. The improvement of student's activity in the experimental class showed that learning activity ran effectively. This result in line with Warsita's statement that a learning activity will run effectively if the student involved actively in organizing and founding the information. (Warsita, 2008). Wulandari (2011) stated the one of learning model that can solve the problem is the PBL model.

Students who learn to solve a problem will apply the knowledge they have or try to find out the experience needed (Adolphus, Alamina, Aderonmu, Education, and State, 2013; Bacong and S, 2015; Hake, 1998). In this situation, students integrate knowledge and skills simultaneously and apply them in relevant contexts. Learning can be more meaningful and can be expanded when students are dealing with cases where the concept is used. The facilitator presents the scenario or problem, and in the group, students carry out various activities (Lsaksen and Lauer, 1998; Wenno, 2010). First, brainstorming is carried out through all group members expressing opinions, ideas, and responses to scenarios freely, so that various alternative viewpoints can emerge. Each group member has the same right in giving and conveying ideas in discussions and documenting their own views in the working paper.

Also, each group must look for terms that are less well known in the scenario and try to discuss their intentions and their meanings. If there are students who know the meaning, immediately explain it to other friends. If there is a part that cannot be solved in the group, it is written in the group problem. Furthermore, if there is a part that cannot be solved in the group, it is written as an issue in the group's problem. Second, to make alternative selections to choose more focused opinions. Third, determine and carry out the division of tasks in groups to find references to solve the issues that were obtained. The facilitator validates the choices students make. At the end of the step, students are expected to have a clear picture of what they know, what they don't know, and what knowledge is needed to bridge it (Adolphus *et al.*, 2013; Retno, Sunarno, and Marzuki, 2019). To ensure each student follows this step, defining the problem is done by following the instructions.

The PBL model is a learning model that

collaborate in problem-solving and founding the concept independently. This model is sufficient to improve creative thinking skills because the student was given the freedom to state their ideas from the inside of themselves and the environment that supports their learning activities (Tan, 2009).

Abanikannda (2016) stated that problem-based learning became a practical pedagogic approach insight of affective and pedagogic changes. Especially in the medical, architecture, and engineering fields for more than forty years.

Uce (2016) stated that in science learning, the PBL model helps the students to improve their ability in learning science procedures are namely observation, measurement, communicating, prediction, determining variables, suggesting a hypothesis, planning, experiment, and many other.

Hermawati stated that the concept mastery would be better if the students were getting involved in the learning activity processes. (Hermawati, 2012).

#### 4. CONCLUSIONS:

It can be concluded that the applying of the PBL model has a significant effect on improving the self-confidence and concept mastery of the student in the electrochemistry topic. Problem Based Learning (PBL) is a learning model that encourages to be more active and maximize the ability of self-confidence to get solutions to problems in the real world. By implementing the PBL model, students can become more competent in solving and taking answers to a problem. Also, this method designs issues that motivate them to gain valuable knowledge so that they have their learning strategy and the ability to participate in discussion groups. The learning process uses a systemic approach to solving problems or challenges needed in everyday life. It has shown by the "very high" average percentage of the PBL implementation. The average n-Gain value of self-confidence is "medium" and "high" for concept mastery and also the value of size effect that categorized as "huge."

## RESUMO

As algas epífitas aderentes às plantas aquáticas são um elo essencial na composição da cadeia alimentar de qualquer ecossistema. As algas epífitas atuam como produtoras primárias da cadeia alimentar no ecossistema aquático e como alimento natural para o zooplâncton herbívoro e peixes. Este estudo teve como objetivo detectar a presença de colônias de algas através de sensoriamento remoto e analisar fatores que afetam o crescimento de algas por meio de levantamento de campo e interpretação visual de imagens de satélite no lago Um El-Naaaj. As amostras foram coletadas em seis locais no lago Um El-Naaaj no período de novembro de 2018 a junho de 2019. As amostras de algas foram coletadas de partes submersas de plantas aquáticas emergentes (macrófitas aquáticas *Phragmites australis*) e armazenadas em sacos plásticos com pouca água do ambiente e soluções para a preservação no campo e no laboratório. Amostras de água foram coletadas para estudar os fatores nutricionais que influenciam o crescimento das algas, incluindo a concentração de fosfato, nitrato e sílica (dióxido de silício). Os resultados mostraram que os valores de fósforo total apresentaram aumento de 1,0, 0,9 e 0,8 mg/L, em janeiro, nos locais 2, 5 e 6, respectivamente. O valor mais alto do nitrato foi de 11,2 mg/L, em dezembro, no local 5, enquanto os menores valores de concentração foram em novembro (2,2 mg/L no local 6, e 3,7 mg/L no local 4). Além disso, a menor concentração de silicato foi de 0,4 mg/L, em novembro, no local 2, ao passo que a maior foi 2,4 mg/L, em junho de 2019, no local 6. Com base nos achados, é possível concluir que, durante o inverno, o nível da água aumentou devido às chuvas. Por esse motivo, as concentrações de nutrientes foram baixas durante o último período. Além disso, com o uso de mapas e técnicas de sensoriamento remoto, é possível determinar os valores esperados em torno da localização da estação como leituras preditivas futuras que compensam a dificuldade de alcançar essas áreas.

**Palavras-chave:** Concentração de  $\text{NO}_3$ ,  $\text{PO}_4$  e  $\text{SiO}_2$ , Algas Nutrientes, Técnicas de Sensoriamento Remoto, Pântanos Um El-Naaaj, Qualidade da Água.

## ABSTRACT

Epiphytic algae adherent to aquatic plants are an essential link in the composition of the food chain of any ecosystem. Epiphytic algae act as primary producers of the food chain in the aquatic ecosystem and as natural food for herbivorous zooplankton and fish. This study aimed to detect the presence of algae colonies through remote sensing and to analyze factors that affect the growth of algae through field survey and visual interpretation of satellite images in Lake Um El-Naaaj. Samples were collected from six locations on Lake Um El-Naaaj from November 2018 to June 2019. The algae samples were collected from submerged parts of emerging aquatic plants (aquatic macrophytes *Phragmites australis*) and stored in plastic bags with little ambient water and solutions for preservation in the field and the laboratory. Water samples were collected to study the nutritional factors that influence the growth of algae, including the concentration of Phosphate, Nitrate, and Silica (silicon dioxide). The results showed that the values of total phosphorus increased by 1.0, 0.9, and 0.8 mg/L, in January, in places 2, 5, and 6, respectively. The highest nitrate value was 11.2 mg/L in December at site 5, while the lowest concentration values were in November (2.2 mg/L at site 6 and 3.7 mg/L at site 4). Besides, the lowest

silicate concentration was 0.4 mg/L in November at site 2, while the highest was 2.4 mg/L in June 2019 at site 6. Based on the findings, it is possible to conclude that, during the winter, the water level increased due to the rain. For this reason, nutrient concentrations were low during the last period. Also, with the use of maps and remote sensing techniques, it is possible to determine the expected values around the station's location as future predictive readings that compensate for the difficulty of reaching these areas.

**Keywords:**  $NO_3$ ,  $PO_4$ , and  $SiO_2$  concentration, Nutrient Algae, Remote Sensing Techniques, Um El-Naaj Marshes, Water Quality.

## المخلص

تعتبر الطحالب الملتصقة بالنباتات المائية حلقة مهمة في تكوين السلسلة الغذائية لأي نظام بيئي. تمثل الطحالب الملتصقة بالنباتات كمنتج رئيسي للسلسلة الغذائية في النظام البيئي المائي وكغذاء طبيعي للعوالق الحيوانية والأسماك العاشية. هدفت هذه الدراسة للكشف عن وجود مستعمرات الطحالب وتحليل العوامل المؤثرة على نمو الطحالب من خلال المسح الميداني والتفسير المرئي لصور الأقمار الصناعية في بحيرة أم النعاج. تم جمع العينات من ستة مواقع في بحيرة أم النعاج من شهر تشرين الثاني 2018 إلى شهر حزيران 2019. جُمعت عينات الطحالب من الأجزاء الغاطسة للنباتات المائية من نبات الطحالب المائية الناشئة (القيصوب الاسترالي). جُمعت عينات النباتات في أكياس بلاستيكية مع القليل من الماء البيئي واستخدمت محاليل للمحافظة على الطحالب في الحقل والمختبر. تم جمع عينات المياه لدراسة العوامل الغذائية المؤثرة على نمو الطحالب منها تركيز الفوسفات والنترات والسيليكا (ثاني أكسيد السيليكون). أوضحت النتائج أن قيم الفوسفور الكلي أظهرت ارتفاع (1.0، 0.9، و 0.8) ملغم في شهر كانون الثاني في المواقع 2، 5، و 6 على التوالي. أعلى قيمة للنترات كانت تركيز 11.2 ملغم في شهر كانون الأول في الموقع 5، وأدنى قيمة نترات تركيز 2.2 ملغم في شهر تشرين الثاني في موقع 6 و 3.7 ملغم في الموقع 4. كما أن أدنى قيمة للسيليكا كانت 0.4 ملغم في شهر تشرين الثاني في موقع 2 وأعلى تركيز 2.4 ملغم في شهر حزيران من 2019 في الموقع 6. بناء على النتائج يمكن استنتاج ارتفاع مستوى الماء خلال فصل الشتاء بسبب الأمطار، لهذا السبب كانت تراكيز المغذيات منخفضة خلال الفترة الأخيرة، كما أن استخدام خرائط تقنيات الاستشعار عن بعد للتنبؤ بالقيم المتوقعة المحيطة بموقع المحطة كقرارات تنبؤية مستقبلية تُعوض عن صعوبة الوصول إلى هذه المناطق.

**الكلمات المفتاحية:** تركيز النترات، والفوسفات، السيليكا، مغذيات الطحالب، الاستشعار عن بعد، هور ام النعاج، نوعية المياه.

## 1. INTRODUCTION:

Epiphytic algae are found attached on surfaces of plants like mosses, other algae, and higher plants. Benthic algae require enough light for growth and suitable sites for connecting like submerged aquatic plants and emergent aquatic plants that found at the edge of the water body (Edward and David, 2010). Epiphytic algae play a vital role in the freshwater ecosystems because they are sources of primary production and an excellent nutrition source for the zooplankton (herbivores and for fish) (Graham *et al.*, 2009). Furthermore, they participate in sediment stabilization and regulation of the nutrients cycle (AL-Hassany and Hindi, 2016; AL Naqeeb *et al.*, 2020).

Epiphytic algae move the energy from the sediment to the water column (Salman *et al.*, 2013) and play a crucial function in the photosynthesis process transforming inorganic materials into organic ones. Also, it recycles nutrients and contributes to oxygen production via photosynthesis (Pouličková *et al.*, 2008). Phosphorus is a major ingredient that all organisms need, including algae, to build up nucleic acids (RNA and DNA), energy materials (ATP and ADP), and plasma membranes (Jarvis, 2000).

The importance of total phosphorus is due to the possibility of being used by aquatic organisms as a source of Phosphate after

conversion to inorganic phosphorus by the group of enzymes (Phosphatase), and dissolved total phosphorus is a determining factor for the growth of algae (McDowell and Sharpley, 2001).

Phosphorus often shows low concentrations in natural Waters. Algae are characterized by their ability to use the optimum concentration of phosphorus available for absorption and storage at concentrations beyond their need and more than what is found in the médium. This is called Luxury Uptake. Mixing from rain helps to release Phosphate from sediment, a source of water-soluble Phosphate. Nitrogen is a major component of algal growth and has an important role in cell division and some metabolic activities such as the building of fatty acids and proteins in algal cells (Boney, 1975). Fatty acids are the main source of Nitrogen in water, and its presence is associated with organic matter in water because it is a determinant of primary productivity in some environment (Ault *et al.*, 2000).

Silicon dioxide,  $SiO_2$ , also known as Silica, is a major nutrient for the growth of diatoms in particular to build their structures (Reynolds, 1984). It is noted that the rate of dissolution of Silica has an essential role in regulating the pH as it acts as buffer solution Buffering Solution, and most natural water contains the element of Silica abundantly and available to diatoms in the basal water than acidic water (Wen and Chen, 2000; Hassan *et al.*, 2012). To study the growth of algae

and its effect on nutrients in the water surface.

A remote sensing program has been used. This progress has helped to achieve the accuracy in obtaining information from orthophoto imagery (aircraft, aerial photo, and satellite); it has become a basic science used to solve many issues related to land, atmosphere, surface phenomena and natural conditions without contact with any variances, through the amount of collection information provided and manipulation with digitization by high technology (Lillesand *et al.*, 2015; Hadi, and Mashee, 2017).

Sensing provides a unique method for obtaining land surface temperature (LST) information at the regional and global scale since most of the energy detected by the sensor in this spectral region is directly emitted by the land surface (Mashi, 2018).

The definitions interpolation process technique is making assumption areas that are closing to one another, which are corresponding to alike than those nearest apart, which led to clear predict values for any unmeasured regions, which influence those farther away. The inverse distance weighting (IDW) technique uses the values measured in observation stations to predict the expected values surrounding the station location as future predictive readings that compensate for the difficulty of reaching remote areas (Mitchel, 2005; Al Ramahi and Al Bahadly, 2017).

This study aimed to detect the presence of algae colonies that are environmentally friendly and community and analyze factors affecting algal traits through field survey and visual interpretation of satellite images and the use of statistical methods and theories.

## 2. MATERIALS AND METHODS:

### 2.1. Study area

The study area in Maysan Province that in the south of Iraq located in Universal Transverse Mercator (UTM) is in wright top 618607.7, 3632754.577 meter, and 770955.209, 3449601.505 meter in the left top. The Huwaizah marshes are located within the governorate of Maysan to the east of the Tigris River. The Huwaizah is bordered to the east and southeast by transnational area with Iran; to the south and southwest by the Basrah Governorates administer active boundary. The Huwaizah marshes represent the northeast corner of the property, with a total surface area of 90,691ha of primarily freshwater marsh.

The Huwaizah is the first national site that declared a Ramsar site for wetlands of international importance (Hassan *et al.*, 2012; Garstecki and Amr, 2011). Um El-Naaj lake, it is one of the most massive open water bodies partially dried during the marshes drying process in 1990. It is located in the northwest part of the Hawizeh marsh in Universal Transverse Mercator (UTM) is in wright top 5294772.863, 3523084.449 meter, and 5308522.835, 3511666.143 meter in left bottom, covering an area of between 140 and 200 km<sup>2</sup> (Garstecki and Amr, 2011). Six sites were selected in Hor Al Huweiza Um El-Naaj lake identified by Ground Positioning System (GPS), (Table 1 and Figure 1).

The algae samples were collected from the submersible aquatic macrophyte plant (*Phragmites australis*) in plastic bags with little of the environment water. Formalin 4% was used for the preservation of algae in the field. Lugol's solution was also used to keep the original characteristics of the samples. Lugol was prepared by dissolving 20 g of Potassium Iodide in 200 ml of distilled water. After, 10 g of Iodine crystals were added; then, glacial acetic acid was added to the mixture, and this solution was preserved in a dark bottle and used by a proportion of 1% (1mL of the solution to every 100 mL of the sample that contains algae) (Prescott, 1964).

### 2.2. Epiphytic Algae Colony

Epiphytic algae attached to plants or to artificial surfaces contribute to taking the phytonutrients present from the water column in the growing season, as they have a role in removing 80% of ammonium, 15% of nitrates and 70% of the adequate soluble phosphorus entering the water surface within 15 days of exposure to these plant nutrients as these high removal rates increase the growth of adherent Epiphytic algae and then use it to treat water-rich in plant nutrients.

The rate of taking phosphorous by adherent Epiphytic algae ranges from 1-3 mg phosphorous/m<sup>2</sup> of wetland area per week, so many of these algae are essential consumers of phosphorus from the water column. Therefore algae is vital evidence of the availability of plant nutrients and pollution as well as being a candidate for materials Water suspended solid (Morgan and Kitting, 1984; Cronk and Mitsch, 1994; Dere *et al.*, 2002).

Given the great environmental importance of algae, as it is an important factor in determining the nutritional level of any ecosystem, this has led to the researchers' interest in studying it

qualitatively and quantitatively (Figure 2).

### 2.3. Total Nitrogen ( $\mu\text{g/L}$ )

The total Nitrogen in the sample was converted to Nitrate in the digestion method with potassium persulphate. According to Rice *et al.*, 2012; Salman *et al.*, 2017, 25 mL of the sample were put in an autoclave  $121^{\circ}\text{C}$  for 30 minutes after the addition of 0.3 g of potassium persulphate; then, it was cooled to the room temperature and pH regulated with NaOH and HCl solution to reach 7 - 9; later, the volume was completed to 100 mL with  $\text{NH}_4\text{Cl}$ -EDTA concentrate solution. After that, the sample passed through the Cadmium column, and the given sample gathered after neglecting the first 25 mL. The first reagent Sulphanilamide has been added, and the sample was put in the darkness for 4 - 6 minutes. The second reagent, naphthyl ethylenediamine-dihydrochloride, has been added, and, finally, after 10 - 12 minutes, the absorption has been measured by the spectrophotometer on wavy length 543 nanometers.

### 2.4. Total Phosphate ( $\text{mg/L}$ )

The total Phosphate was measured by the method of absorption (Rice *et al.*, 2012; Parsons *et al.*, 1984). A total of 100 mL of the sample was put in the autoclave  $121^{\circ}\text{C}$  after the addition of 5 mL of sulphuric acid 1N and 0.7 g of potassium persulphate. Then, it was cooled to the room temperature and treated with 10 mL of the reduced solution composed of ascorbic acid, antimony potassium tartrate, ammonium molybdate, and diluted sulphuric acid. The color was changed to blue. Finally, the absorption was measured by the spectrophotometer on 885-nanometer wavy length.

### 2.5. Reactive Silicate (Silicon Dioxide $\text{SiO}_2$ , $\mu\text{g/L}$ )

The reactive silicate was measured according to the method described by Rice *et al.*, 2012; Salman *et al.*, 2017; and Parsons *et al.*, 1984. A total of 25 mL of the sample was taken. Another 10 mL of ammonium molybdate was added. Then, the flask was shaken. After 10 minutes, 15 mL of the reduced solution (sulfide, oxalic acid, and sulphuric acid) was added. The sample was then left 2-3 hours until the blue color stabilizes. Finally, the absorption was measured by the spectrophotometer on the 810-nanometer wavy length.

## 2.6. Remote Sensing (RS) Processing

Data of remote sensing techniques used in this study included three Imaginary, three periods of time, Landsat-8 OLI images Shaped and rectangular dimensions path: 167 km and row: 38 km. These data were acquired on the 22<sup>nd</sup> November 2018, 24<sup>th</sup> December 2018, and 20<sup>th</sup> January 2019. These periods matched with the timing of fieldwork data collection. The images were downloaded from the United States Geological Survey (USGS, 2017; Al-Ramahi, 2020).

The Landsat images were first converted to Top-of-Atmosphere (TOA) radiance using radiometric calibration coefficients in the metadata file. ArcGIS 10.5 is the digital image processing software used to process the Landsat 8 IMAGES. Twenty-six ground control points (GCPs) were selected from the images and rectified to the UTM (Universal Transverse Mercator). World Geodetic System 1984 (WGS 84) projection using coordinates obtained from Global Positioning System (GPS), (20). For the spatial interpolation of the geometric correction, the image's original digital numbers (DNs) were preserved by subsequently using a Bilinear resampling method. After geometric correction, the images were atmospherically corrected. The atmosphere may potentially affect image by absorbing, scattering, and refracting light.

## 3. RESULTS AND DISCUSSION:

### 3.1. Analysis of Factors Affecting Algal Trait ( $\text{NO}_3$ , $\text{PO}_4$ , $\text{SiO}_2$ )

The samples were analyzed in the laboratory and extracted the values of ( $\text{NO}_3$ ,  $\text{PO}_4$ ,  $\text{SiO}_2$ ). The data was tabulated to explain it in Geographic Information Systems (GIS) programs, which is the best application program to simulate spatial data with remote sensing techniques, and through Landsat 8 satellite imagery.

### 3.2. Spatial Analysis

The spatial analysis of these samples and the simulation of the study area maps were made, aiming to know the effect of these factors on the water quality and algae present in this region. Moreover, it was intended to know the unknown areas in which it is difficult to obtain data (the prediction process). Through these six stations, data is not sufficient to cover the study area. Through the application of theories and statistical

methods used in geographic information systems (GIS) (Al Ramahi, and Al Bahadly, 2020), it was possible to know and cover the study area of Um El-Naaj lake in Al-Hweizeh marsh (Table 2).

### 3.3. Factors Affecting ( $\text{PO}_4$ ) Analysis

Phosphorus is an important nutrient, representing an intermediate component of energy metabolism (Schulze *et al.*, 2005). Phosphorus is found in many forms and may be present in the soluble or pigmented form. The pigmented way is found mainly in algae and aquatic plants (Smith, 2004). The dissolved form is found in various forms such as Orthophosphate, Polyphosphate, and the Orthophosphate may be rapidly represented by living organisms, in natural water (Wetzel and Likens, 2013). The concentration of total phosphorus raised 1.0, 0.9, and 0.8 mg/L, in January, at sites 2, 5, and 6, respectively (Table 2). The lowest concentration was found in November and December on all sites. The results of phosphorus concentrations showed a significant increase that may be a result of high water levels or rainfall that washed off phosphorus compounds from soil to the river when washing agricultural land fertilized with phosphate fertilizers (Sims and Sharpley, 2005). The high concentration of Phosphate leads to the dense growth of algae, which in turn reduces light transmittance and dissolved oxygen concentrations, resulting in slow decomposition of organic matter and nutrient recycling (McDowell and Sharpley, 2001; Adamus, 2001). On the other hand, low concentrations may be explained by the consumption of Phosphate by algae and aquatic plants (Kassim and Al-Saadi 1995) (Figures 3 and 4).

### 3.4. Factors Affecting ( $\text{NO}_3$ ) Analysis

The Nitrate is the predominant form of inorganic Nitrogen in the aquatic environment (Smith, 2004), and the variation in nitrogen compounds is due to increased human activity in agriculture and industry and the resulting residues of a container on nitrogen compounds (Johnson, 2004). The results showed that the lowest nitrate concentrations were 2.2 mg/L in November at site 6, and 3.7 mg/L in the same month, but site 5. In December, the highest concentration was 11.2 mg/L (Table 2).

The high concentration of nitrates is due to the washing of the land adjacent to the river and the erosion of the soil containing nitrogen compounds from the animal residues (Al-Nimma, 1982). The decrease in Nitrate may be due to its

consumption of revival, which is the primary source of plants in general and algae in particular (Saad and Antoine 1978) (Figure 5).

### 3.5. Factors Affecting ( $\text{SiO}_2$ ) Analysis

Silicates are widely found in Iraqi waters, and they are of great importance for diatoms as they are needed for the building of their siliceous skeletons (Goldman and Horne, 1983). Its concentration ranges from 1-10 mg.L<sup>-1</sup> in natural water. The concentration of Silica between 0.5-0.8 mg.L<sup>-1</sup> is determinant for the growth of diatoms (Reid, 1961). It plays a vital role in increasing the number of diatoms and the length of their survival (Chatterjee, 2014). High concentrations of silicate characterize Iraq waters. This is due to the geological nature of land in which Tigris and Euphrates Rivers flow. The results showed the lowest concentration of silicate was 0.4 mg/L, in November, at site 2; The highest concentration was 2.4 mg/L in June 2019 at site 6, and there were no significant spatial differences among the study sites. In general, the active silicate concentrations in the studied area exceeded the need for phytoplankton. This phenomenon is known in Iraqi waters, which have high concentrations of active silicates. The concentrations of silicates obtained are not consistent with the study of (AL-Saeedy, 2014; AL-Hassany and Hindi, 2016), shown in Figure 6.

## 4. CONCLUSIONS:

The samples were analyzed in the laboratory and extracted the values of  $\text{NO}_3$ ,  $\text{PO}_4$ ,  $\text{SiO}_2$ . The data was tabulated to analyze in Geographic Information Systems (GIS) programs. The nutrient values ranged from 0.01 - 1 mg/L for  $\text{PO}_4$ ; 2.2 - 11.2 mg/L for  $\text{NO}_3$ ; and 0.4 - 2.44 mg/L for  $\text{SiO}_2$ . Also, it can be concluded that, during the winter, the water level was increased due to rainfall; that is, the nutrients concentrations were low during the last period.

The Sample concentrations were useful in determining the acceptable water quality, which helped in the presence of a great diversity of some species in the marshes (Um El-Naaj lake). By using remote sensing techniques, maps were produced to predict the expected values surrounding the station's location as future predictive readings that compensate for the difficulty in reaching these areas.

**RESUMO**

O artigo apresenta os resultados de um estudo experimental do grão de cevada da cultivar Baisheshek tratado com uma mistura de íon-ozônio. O objetivo deste estudo foi desenvolver uma tecnologia inovadora para o processamento de cevada com uma mistura íon-ozônio, a fim de aumentar seus parâmetros tecnológicos, produtividade, qualidade e segurança de grãos. O Cazaquistão aumentou drasticamente a exportação de cevada e todos os agrônomos, produtores e criadores estão migrando ativamente para o desenvolvimento dessa cultura, enquanto aumentam a produção, a produtividade, melhoram a qualidade do produto, reduzem suas perdas e garantem a segurança do armazenamento, que é uma tarefa urgente. Os microrganismos desempenham um papel importante durante o armazenamento, estes penetram nos produtos agrícolas de várias maneiras e, se caírem em condições desfavoráveis de armazenamento após a colheita, os produtos agrícolas se deterioram rapidamente, substâncias nocivas se acumulam - toxinas, fungos e outros, o que reduz o valor da mercadoria. Para resolver esses problemas, foram realizados estudos experimentais em cevada da cultivar Baisheshek, tratada com uma mistura de íon-ozônio com e sem o uso de pressão excessiva (cavitação). O delineamento fatorial completo calculado das experiências dos 2<sup>3</sup> (8 experimentos) e 2<sup>4</sup> (16 experimentos) possibilitou a obtenção de equações de regressão descrevendo a alteração nas propriedades semente, físicos bioquímicos e fisiológicas da cevada de Baisheshek. A solução de um modelo abrangente de otimização de programação para diferentes indicadores de cevada permitiu estabelecer ótimos modos de processamento tecnológico e níveis alcançáveis de qualidades tecnológicas de grãos. O efeito da tecnologia proposta para o tratamento de íons ozônio e cavitação íon ozônio foi a mistura do íon ozônio, que produz a desodorização, desinfecção de grãos, de acordo com processos físicos e químicos, aumenta o valor biológico, acelera os processos de metabolismo de grãos. Os estudos realizados para melhorar a germinação, viabilidade e força de crescimento mostram uma imagem bastante clara em termos de seu valor final. Observações fenológicas mostraram que os efeitos do tratamento com cavitação íon ozônio e cavidade íon ozônio são desencadeados após 25 a 30 dias. Verificou-se que a maior tendência à superioridade é observada no tratamento da cavitação íon ozônio, seguido pelo íon ozônio, e a amostra de controle está significativamente atrás.

**Palavras-chave:** cevada, variedade, de tratamento, de íon-ozônio, cavitação.

**ABSTRACT**

The article presents the results of an experimental study of Baisheshek barley grain treated with an ion-

ozone mixture. This study aims to develop an innovative technology for processing barley with an ion-ozone mixture in order to increase their technological parameters, yield, quality, and grain safety. Kazakhstan has sharply increased the export of barley, and all agronomists, producers, and breeders are actively moving to the cultivation of this crop, while increasing production, productivity, improving product quality, reducing their losses and ensuring storage safety are an urgent task. Microorganisms play an important role during storage, they fall into crop production in a variety of ways, and if they fall into unfavorable storage conditions after harvesting, crop production quickly deteriorates, harmful substances such as toxins, mold, and others accumulate in it, which reduces the commodity value. To solve these problems, experimental studies were conducted on barley of the Baisheshek cultivar treated with an ion-ozone mixture with and without using excess pressure (cavitation). The calculated full-factorial design of experiments of the 2<sup>3</sup> (8 experiments) and 2<sup>4</sup> (16 experiments) degrees made it possible to obtain regression equations describing the change in the seed, physico-biochemical, and physiological properties of barley of the Baisheshek variety. The solution of a comprehensive model for optimizing programming for different barley indices made it possible to establish optimal technological processing modes and achievable levels of technological qualities of grain. The effect of the proposed technology for ion-ozone and ion-ozone cavitation treatment is the ion-ozone mixture, which produces deodorization, disinfection of grain, following chemical-physical processes, increases biological value, accelerates the processes of grain metabolism. Studies conducted to improve germination, viability, and growth strength show a reasonably clear picture in terms of their ultimate value. Phenological observations showed that the effects of ion-ozone and ion-ozone cavitation treatment is triggered after 25-30 days. It was found that the greatest tendency for superiority is observed with ion-ozone cavitation treatment, followed by ion-ozone, and the control sample is significantly behind.

## АННОТАЦИЯ

В статье приведены результаты экспериментальных исследований зерна ячменя «Байшешек», обработанного ион-озонной смесью. Целью данного исследования является разработка инновационной технологии обработки ячменя с ион-озонной смесью с целью повышения их технологических показателей, урожайности, качества и обеспечения безопасности зерна. Казахстан резко нарастил экспорт ячменя и все агрономы, производители и селекционеры активно переходят к выращиванию этой культуры, при этом увеличение производства, урожайности, повышения качества продукции, сокращение их потерь и обеспечение безопасности при хранении являются актуальной задачей. При хранении большую роль играют микроорганизмы, в растениеводческую продукцию они попадают разнообразными путями и если они попадают после уборки урожая в неблагоприятные условия хранения, то растениеводческая продукция быстро портится, в ней накапливаются вредные вещества – токсины, плесень и другие, что снижает товарную ценность. Для решения данных проблем были проведены опытно-экспериментальные исследования ячменя сорта «Байшешек», обработанного ион-озонной смесью с и без использования избыточного давления (кавитация). Рассчитанные полнофакторные планирования экспериментов 2<sup>3</sup> (8 опытов) и 2<sup>4</sup> (16 опытов) степени позволили получить уравнения регрессии, описывающие изменение семенных, физико-биохимических и физиологических свойств ячменя сорта «Байшешек». Решение комплексной модели оптимизации программирования по разным показателям ячменя позволило установить оптимальные технологические режимы обработки и достижимые уровни технологических качеств зерна. Эффектом предлагаемой технологии по ион-озонной и ион-озон-кавитационной обработке является ион-озонная смесь, которая производит дезодорацию, дезинфекцию зерна, в соответствии с квантовофизическими процессами, повышает биологическую ценность, ускоряет процессы метаболизма зерна. Проведенные исследования, направленные на повышения всхожести, жизнеспособности и силы роста показывают достаточно четкую картину в смысле их окончательной ценности. Фенологические наблюдения показали, что эффекты от ион-озонной и ион-озонной кавитационной обработки срабатывает через 25-30 дней. Были установлены, что наибольшая тенденция превосходства наблюдается при ион-озонной кавитационной обработке, затем следует ион-озонная, а контрольный образец существенно отстает.

## 1. INTRODUCTION

Carriers of electricity in liquids are called ions: cations (positive ions, that are atomic ions) and anions (negative ions, that are molecular ions). Studying the effect on animals and

vegetation of animals only atomic and only molecular ions obtained artificially immediately revealed a remarkable difference in the biological effect of ions: molecular air ions turned out to be a biologically beneficial factor, atomic air ions most often had an adverse or even harmful effect

on the body. After it was firmly established in many experiments that molecular ions have a beneficial effect on the viability of animals and plants, increasing their growth and weight, protecting against several diseases, contributing to the conservation and proceeding from some theoretical facts, it was found that the carrier of negative charges polarity in atmospheric air is the oxygen of this air (Maemerov *et al.*, 2006; Urazaliev, 2012; Sagitov *et al.*, 2012).

Grains infected with pathogenic microorganisms are often the cause of mass human diseases and the death of birds and animals, and products prepared from them quickly deteriorate, harmful substances (toxins) accumulate, which reduces nutritional value. Of particular danger are mold fungi, which cause the accumulation of toxins in the finished product. The most dangerous is the complex toxin is aflatoxin, which affects both individual organs and entire body systems. Thus, microorganisms not only lead to the development of infection, but also to toxicosis, which causes great harm to humans, animals, and birds – inhibits growth and development, with severe bactericidal pollution lead to death (Naleev, 1993; Malin, 2005; Tikhonov *et al.*, 2006; Voblikov *et al.*, 2001).

The solution to this problem is ozone technology. The practical application of ozone technology was carried out in the research laboratory of food and processing industries of the Almaty Technological University, which allows cleaning grain, disinfection, increasing yields up to 20%, acquiring good sowing qualities with hereditary transmission to their offspring (Kokhmetova *et al.*, 2014; Maemerov, 2004).

In post-harvest processing, get refined crop products, improve the baking qualities of wheat. By combining the electrical circuits of the ionizer and ozonator installation, an ion-ozonator installation is developed that neutralizes all harmful synthesized impurities. As a result, a pure ion-ozone mixture without harmful side impurities is obtained. The oxides of nitrogen and carbon, together with other harmful impurities and radiation during the synthesis of the ion-ozone mixture in the ion-ozonator installation, are neutralized.

The technology of ion-ozone cavitation treatment of seeds of sowing grain materials is environmentally safe and does not use chemicals and types of radiation harmful to humans, animals, and the environment.

The use of a cavitation installation before sowing almost destroys insect pests, eliminates

the need for pesticides, eliminates plant diseases, activates plant growth forces and eliminates the lack of nitrogen and water in plant leaves, which will significantly reduce chemical and soil pollution pesticides and reduce the use of mineral fertilizers (Erkmen, 2001; Akulichev, 1978; Pirsol, 1975; Ivanov, 1980; Maemerov *et al.*, 2011).

Structural and functional changes in the membrane formations of cells and intracellular organelles, which in our understanding are targets of ion-ozone cavitation, are the basis for increasing the biological value of the processed seed and food grains and obtaining the effect.

As a result of this interaction, a physicochemical basis is created for changing metabolic processes associated with proton and electron transfers in cell membranes. On this basis, successive nonspecific reactions of the cell and the organism as a whole arise. Differences exist only in the biophysical subtleties of the interaction of ion-ozone cavitation and biological tissues (Sereev, 2014; Baymagambetova *et al.*, 2014; Kim *et al.*, 2003).

The technical solution to the problem is achieved by the simultaneous processing of the moistened grain with an ion-ozone mixture in the cavitation zone with an overpressure of 2.0-6.0 at in the moistened grain processing tank with a grain processing exposure of 5.0 to 20.0 minutes, with an ozone concentration of 2.0 to 6.0 mg/m<sup>3</sup>, molecular ions from 1000 to 5000 m<sup>3</sup>. After the processing time has elapsed in the tank for ion-ozone processing of moistened grain, a sharp discharge of excess pressure to atmospheric pressure occurs (Iztaev *et al.*, 2013; Iztaev *et al.*, 2018c).

Ion-ozone treatment of moistened grain in the cavitation field is carried out at an ozone concentration of 2 mg/m<sup>3</sup> to 6 mg/m<sup>3</sup> and from 1000 units/cm<sup>3</sup> to 50,000 units/cm<sup>3</sup> of molecular oxygen ions, depending on:

- increase the biological value (2,0–10,0 mg/m<sup>3</sup>);
- destruction of harmful microorganisms and grain pests, grain disinfection, and rodent disinfection (20,0–80,0 mg/m<sup>3</sup>) (Iztaev *et al.*, 2018a).

At the post-harvest stage, to obtain purified grain mass from pests improved the technological qualities of grain crops. From year to year, environmental requirements are violated, and in this regard, special attention is being paid to the food safety of foodstuffs consumed by the

population. In meeting the requirements of environmental friendliness and safety of the production of products from seed preparation, in the processes of cultivation, harvesting, transportation, primary processing at grain enterprises, storage, and further processing, the production of flour, cereals, animal feed, bread, pasta, flour and confectionery products and other food products first of all pay attention to the original quality of crops used for this chain (Urazaliev *et al.*, 2010; Knapp *et al.*, 1974).

In this regard, special experimental studies have been carried out to identify the environmental friendliness and food safety of ion-ozone and ion-ozone cavitation technology, processing by electro-ion-charged particles of the air-flow during the cultivation of grain crops.

To improve the seed, yield and technological qualities of grain during short-term and long-term storage, ion-ozone flow processing of grain products in a stream of electrically charged particles is effective, which makes it possible to use the potential of biological and environmental resources.

In order to increase the efficiency of the use of crop products, scientists of the Almaty Technological University have developed various electrophysical methods for processing, storage, and processing of crop products: ion-ozone, ion-ozone cavitation processing of crop products, which contribute to improving the quality and preservation of grain.

The controlled effect on the biological environment of the ion-ozone mixture using ion-ozone cavitation allows for intensive bubbling of biological products of crop production with activation and stimulation, as well as inhibiting viruses, bacteria, spore formations with a delay in the flow of physiological and physicochemical processes in them, with suppression their infectious activity (Tursunbayeva *et al.*, 2019; Iztayev *et al.*, 2018b; Yakiyayeva *et al.*, 2016).

## 2. MATERIALS AND METHODS

The object of the study is the pre-sowing ion-ozone, ion-ozone cavitation treatment of the pre-sowing material, as well as the treatment of sprouts of crop products in the field in the zone of charged particles of molecular and atomic ions. As an object of research, plots of Baisheshek barley varieties were prepared for the treatment of green plants in the full earing phase.

The following regulatory documents were used in this work: GOST 10845-98. Grain and products of its processing. Method for the determination of starch; GOST 10846-91. Grain and products of its processing. Method for determination of protein; GOST 12041-82. Seeds of crops. Method for determination of moisture content; GOST 12042-80 Seeds of crops. Methods for determining the mass of 1000 seeds; GOST 10968-88. Grain. Methods for determining germination energy and germination capacity; ST RK GOST R 51411-2006 Grain and products of its processing. Method for the determination of ash.

Such indicators as the energy of germination and germinability belong to seed characteristics. As seed germinability, there is understood the quantity of normally germinated seeds in the test, taken for the analysis, evaluated as a percentage. The energy of the germination of seeds characterizes an aggregate of the appearance of normal germinants for the term fixed for each culture.

The seeds are couched in the germinators or Petri dishes, placed in the thermostat with a specified temperature condition. As a ground litter (bed), use quartz sand or filter paper. Quartz sand for decontamination has to be well washed and calcined, and filter paper must be sterilized in an exsiccator at a temperature of 130°C within 1 hour. The ground litter is damped before the seed sprouting: quartz sand - to 60% of the full moisture and filter paper and gauze - completely, allowing draining of excess water.

If the seeds are couched on filter paper, then they are arranged in rows at a distance of not less than 0,5-1,5 cm from each other over the ground litter, which is placed on the bottom of the germinator in 2-3 layers. The germinators are closed by the glass plates and are placed in the thermostat. On each of them, there is stuck down a label with the indication of the sample number and test, date of seed laying, and dates of determination of germinability and energy of germination. The majority of grain crops and leguminous plants are couched at a constant temperature of 20 °C. It is necessary to check constantly moistening of the ground litter, without allowing its drying.

The sprouted seeds are counted in two terms: in 3-5 days for determination of the energy of germination and in 7-10 days for determination of germinability. Both indicators are expressed as a percentage of the sprouted seeds to their total in the test. Sprouted seeds are considered those

at which the rootlets or one main rootlet have a length not less than the length of a seed, and a sprout is not less than half of the length of the seed. Average values of germinability and energy of germination of seeds are considered reliable if deviations are expressed in all four tests within  $\pm 2\%$  at average germinability from 98 to 100%;  $\pm 3\%$  – at 95-97,9%,  $\pm 4\%$  – at 90-94, 9% and  $\pm 5\%$  – at 85-89,9%. Otherwise, average values are fixed by the three tests if deviations in them don't exceed admissibly; or the analysis is repeated again if admissible values have only two tests (Odjo *et al.*, 2018; Morales-de la Peña *et al.*, 2019; Naumenko *et al.*, 2018; Singh *et al.*, 2015).

In experimental studies, two methods of processing crops were studied:

- ion-ozone treatment of cereals;
- ion-ozone cavitation treatment of cereals.

Carriers of electricity in liquids are called ions: cations (positive ions, that are atomic ions) and anions (negative ions, that are molecular ions). Ions of air allowed to solve a number of mysteries of atmospheric electricity (thunderstorms, lightnings, electrical conductivity of gases, and others).

Molecular ions differ from atomic ions in greater mobility, greater diffusion coefficient, "greater ionizing force". It has been established that molecular ions arise in the air due to oxygen molecules, and atomic ions due to nitrogen and carbon dioxide molecules.

By combining the electrical circuits of the ionizer and ozonator installation, an ion-ozonator installation has been developed that neutralizes all harmful synthesized impurities, as a result, a pure ion-ozone mixture is obtained without harmful impurities. Oxides of nitrogen and carbon, together with other harmful impurities and radiation during the synthesis of the ion-ozone mixture in the ion-ozonator installation, are neutralized.

When the corresponding voltage of the electric current is applied to the electrodes of the ion-ozonizer, an ion-ozone mixture is formed, in accordance with Figure 1, namely, in the ozone generator, the primary processes of ozone formation from air proceed depending on the amount of applied energy. In accordance with the energy potential, the electrons in the ionization volume in the electric field of the ozone generator accelerate, ionizing the gas, creating an avalanche of new electrons. In this case, the emission of

electrons from the cathode to the anode is formed by positive ions, subsequently rushing towards the cathode, also ionizing neutral atoms and molecules, forming negative ions. Upon collision with the cathode, ions knock electrons out of it, which, falling into the volume, again cause ionization.

Excitation of an oxygen molecule occurs at an electron energy of 6.1 eV and all free electrons are captured by oxygen molecules, as a result of electron energy of 12.2 eV, molecular ions are formed and, with an increase in energy within 19.2 eV, dissociation occurs in oxygen and with the participation of the atom and molecular ions, when the molecule is excited, ozone formation occurs (Figure 2).

Along with this, oxygen, molecular and atomic ions, nitrogen and carbon oxides, atomic oxygen, atomic ozone, and others are formed. With the appropriate energy, the formation of ions, electrons, and molecules is associated with their collision with other particles (electrons, atoms, ions). In this case, the formation of positive ions and free electrons from atoms or molecules with an appropriate degree of ionization accompany the origin of impact ionization. The probability of the occurrence of impact ionization is characterized by an effective ionization cross-section and depends on the kind of ionizable and bombarding particles, depending on the kinetic energy with a certain minimum (threshold) value. This minimum value is probably equal to zero, and, with an increase in energy above the threshold, it first rapidly increases, reaches a maximum, and then, with corresponding energy potentials, decreases (Iztayev *et al.*, 2018d; Kalinina *et al.*, 2016).

The energy that needs to be reported to an atom (molecule) for its ionization is called the ionization energy. If the energy transferred to ionized particles in collisions is large enough, then under certain conditions, a particle can ionize in collisions. In this case, only part of the energy necessary for ionization is transferred to it, and first, the atoms (molecules) in the primary collisions are transferred to the excited state, after which shock ionization occurs, and it is enough to tell the missing energy (equal to the difference between the ionization energy and the excitation energy), multistage ionization occurs. It is possible if collisions occur so often that the particle in the interval between two collisions does not have time to lose the energy received in the first of them. And also, in the same cases when the particle has metastable states, and with

the ability to conserve the excitation energy relatively long, multiple ionization occurs.

The processes associated with impact, multistage, and multiple ionization play an important role in the synthesis of ozone, which occurs in a strong electric field of an ion-ozonator generator. As a result, in such a field, the electrons in the conduction band acquire kinetic energy greater than the bandgap, and electrons are knocked out of the valence band of the molecules with the transformation of the energy of other molecules. At a certain critical field strength, impact, multistage, and multiple ionization leads to a sharp increase in current density, to an increase in ozone concentration, and in the absence of regulation of the energy potential, with repeated ionization, the electrical breakdown is possible.

The ability to transform the energy of nitrogen and carbon into an increase in ozone concentration shows that with an increase in the voltage of the electric current in the ozone generator from 0.5 to 3.0 kV, the rate of ozone formation is higher than after impact ionization. The intensity of ozone formation increases, apparently due to the transformation of the energy of nitrogen and carbon, since the degree of oxygen ionization is 13.618 eV, nitrogen - 14.53 eV, and the degree of carbon ionization - 11.26 eV. When the corresponding energy is supplied during the ionization period, the nitrogen and carbon atoms are able to attract electrons. Namely, the nitrogen atom attracts one electron into the outer orbit, the carbon atom two electrons. As a result, six electrons are obtained in the outer orbit of the nitrogen and carbon atoms, which corresponds to the number of oxygen electrons. Nitrogen and carbon atoms, transforming into oxygen, contribute to the synthesis of ozone.

At the same time, an ion generator having an electric charge of negative polarity produces molecular ions and attracts atomic ions, nitrogen, and carbon oxides having an electric charge of positive polarity, knocking out oxygen not only from the ozone synthesized by it but also from the environment. The synthesized ozone, oxygen, molecular ions, having a negative polarity, slip through an ozone generator having a negative polarity of the electric current and, interacting with each other, form oxygen, and then ozone. Molecular ions, combining with a neutral atom, form a stable molecular ion, and with further connection with the electron 9, form a heavy molecular ion 10.

Positive ion 11 and other positively charged particles from the environment rush to the ion generator, where they are neutralized. Further, ozone enters into a chemical reaction with biological substances or, as an unstable gas, decomposes into oxygen, which subsequently forms other compounds. With a positive polarity of the ion generator 6, we obtain the components of the positive sign ion-ozone technology, that is, atomic ozone, atomic oxygen and atomic ions, nitrogen and carbon oxides harmful to all living things.

Ion-ozone cavitation occurs as a result of a local critical increase in excess pressure above 4 at and a sharp release of excess pressure to the atmospheric environment during product processing. And they can also occur either with an increase in its velocity or with the creation of a sharp drop in excess pressure during the half-cycle of rarefaction (acoustic ion-ozone cavitation), there are other reasons for the effect. Moving with the flow to a region with a higher overpressure or during the half-compression period, the cavitation bubble filled with the ion-ozone mixture slams, emitting a shock wave with an ozone explosion, which facilitates the interaction of the ion-ozone mixture with the processed product. At the same time, bubbling, instant destruction of microorganisms, pests of products of biological origin, on the basis of quantum-physical processes in comparison with similar technologies occurs intensively, the biological value of the product increases more, resistance to external irritants is acquired, and the time of the positive effect of ion-ozone interaction on the processed product is reduced.

Usually, this is achieved due to a critical overpressure of 4 at or more with a sharp release of excess pressure to atmospheric pressure, the design of hydroturbines, or by passing an ion-ozone mixture through a ring-shaped opening that has a narrow inlet and a significantly larger outlet: a forced decrease in pressure leads to ion-ozone cavitation since the ion-ozone mixture tends to the side of a larger volume (with increasing pressure, ozone acquires potential energy to explode). This method can be controlled by devices that control the size of the inlet, which allows you to adjust the process in various environments. The outer side of the mixing valves, along which the ion-ozone-cavitation bubbles move in the opposite direction to cause implosion (internal explosion), is subjected to tremendous pressure and is often made of heavy-duty or rigid materials, for example, stainless steel, stellite. This device is

called the ion-ozone cavitation installation (Kalinina *et al.*, 2018; Zhakatayeva *et al.*, 2020; Zapevalov *et al.*, 2015).

Grain processing was carried out on an experimental ion-ozone cavitation installation, consisting of an ion-ozonator generator 1 and a cavitation capacity 2 (Figure 3).

During ion-ozone treatment, crops are loaded into an ion-ozone cavitation unit pre-filled with an ion-ozone mixture with an ozone concentration of 0.5 mg/dm<sup>3</sup> to 4 mg/dm<sup>3</sup> (or from 0.5·10<sup>-3</sup> to 4·10<sup>-3</sup> mg/cm<sup>3</sup>) and molecular ions ranging from 500 to 60,000 units/cm<sup>3</sup>. In this case, the ratio of ion concentration (units/cm<sup>3</sup>) to ozone concentration (mg/cm<sup>3</sup>)  $C_{i/o}$  is (1-15)·10<sup>-6</sup> units/mg, that is 1-15 million units/mg. Then for 10 to 20 minutes produce ion-ozone ventilation of crops.

In the case of ion-ozone cavitation treatment of grain after ventilation, the cavitation installation is hermetically closed, and the ion-ozone mixture is pumped into the tank until an overpressure of 2 to 4 at is created, after which the overpressure is sharply discharged, while the ozone tends to explode. In this case, a sharp discharge of excess pressure and the power of an ozone explosion adds up. During the explosion, cavitation processes occur, in which the pores of the treated cultures increase, the ion-ozone mixture penetrates more efficiently. At the same time, ozone destroys harmful impurities, and harmful insects, molecular oxygen ions based on quantum-physical processes increase the biological value of the product.

The following factors were selected as factors affecting the properties and quality indicators of the treated crops:

- ratio of ion concentration (units/cm<sup>3</sup>) to ozone concentration (mg/cm<sup>3</sup>)  $C_{i/o}$ , units/mg;
- overpressure (for cavitation treatment)  $P$ , at;
- sample moisture before processing  $w$ , %;
- processing time  $t_1$ , min.

In the experiments for all the studied crops, the following quality indicators were determined:

- $y_1$  – germination energy, %;
- $y_2$  – germination in 5 days, %;
- $y_3$  – germination in 7 days, %;
- $y_4$  – humidity after processing, %;
- $y_5$  – nature, g/l;
- $y_6$  – grain density, g/cm<sup>3</sup>;

- $y_7$  – weight of 1000 grains, g;
- $y_8$  – protein, %;
- $y_9$  – starch, %;
- $y_{10}$  – greenery index, ml.

The same quality indicators were also determined for control (untreated) grain samples.

To optimize the processing regimes of grain crops, the following indicators were selected as target functions:

- for seed properties – germination energy ( $y_1$ );
- for physical properties – density ( $y_6$ );
- for biochemical properties – protein ( $y_8$ );

The rest of the above grain quality indicators were considered as limitations.

### 3. RESULTS AND DISCUSSION

Given the relatively large number of factors, in order to reduce the number of experiments and obtain reliable results in the studies, methods for planning multi-factor experiments were used, in particular, the use of plans for full factor experiments (FFE) of the FFE-2<sup>3</sup> type (for ion-ozone treatment) and FFE-2<sup>4</sup> (for ion-ozone cavitation treatment).

Based on the least-squares studies of the developed algorithms and sequential regression analysis programs (Ostapchuk *et al.*, 1992; Ostapchuk, 2007), regression equations were obtained that adequately (according to the Fisher's Criterion) describe the dependences of the above quality indicators of processed crops, respectively, on conditions and modes of their ion-ozone (IO) and ion-ozone cavitation treatment (IOC).

The concentration of ozone in the ion-ozone mixture is from 2.0 to 6.0 g/m<sup>3</sup>, molecular ions from 1000 to 50,000 units/cm<sup>3</sup>. Exposure time from 5 to 20 min, which is determined to a greater extent by the quality and infection of the grain.

The optimal regimes of ion-ozone processing of seed and food grains identified during experimental studies are of practical value, which made it possible to develop, with a refinement in the engineering calculation of the plant parameters, and to create a laboratory-controlled ion-ozone mixture for processing seed

and food grains.

Quality indicators of control (unprocessed) cereal crops are given in Tables 1. The matrices for planning experiments with the experimental conditions and the results of determining the quality indicators of the treated crops are given in Tables 2 and 3.

here:

$C_{i/o}$  – ratio of ion concentration (units/cm<sup>3</sup>) to ozone concentration (mg/cm<sup>3</sup>), units/mg;  
 $P$  – overpressure (for cavitation treatment), at;  
 $w$  – sample moisture before processing, %;  
 $t_1$  – processing time, min.  
 $y_1$  – germination energy, %;  
 $y_2$  – germination in 5 days, %;  
 $y_3$  – germination in 7 days, %;  
 $y_4$  – humidity after processing, %;  
 $y_5$  – nature, g/l;  
 $y_6$  – grain density, g/cm<sup>3</sup>;  
 $y_7$  – weight of 1000 grains, g;  
 $y_8$  – protein, %;  
 $y_9$  – starch, %;  
 $y_{10}$  – greenery index, ml.

The regression equations obtained based on processing the results of the experiments are given below in the corresponding mathematical models used in optimizing the processing regimes of the cultures studied. All the equations obtained adequately describe the experimental data.

From the data in Tables 1 to 3, it can be seen that during processing, the preparation of seeds of barley of the Baisheshek variety requires bioenergetic activation due to ion-ozone and ion-ozone cavitation treatment. As a result, the germ cells of these cultures pass from the deceased to an active state, and the seed germination energy is manifested rapidly.

With ion-ozone and ion-ozone cavitation treatment of seeds of grain crops, the energy of germination and germination of seeds is significantly increased. It accelerates their germination, increases the productivity of agricultural plants, and the technological quality of food products by 25-30 %. After ion-ozone cavitation treatment of barley seeds, the biological and nutritional value of processed grain seeds increases more intensively due to increased accumulation of proteins, sugars, organic acids, vitamins, and macronutrients in them.

Ion-ozone treatment of the dry and wet state of seeds of grain crops helps to maintain

stability during the storage of barley varieties without increasing acidity and respiratory rate. Ion-ozone cavitation treatment of the dry and wet state of grain seeds allows creating more favorable conditions for the storage of barley varieties compared to ion-ozone treatment.

Data processing and calculations were carried out using the algorithm developed by the Odessa National Academy of Food Technologies and the sequential regression analysis program PLAN. The program first gives the values of all the regression coefficients and their confidence intervals (errors), then checks the significance of the regression coefficients and, after removing all the insignificant coefficients, the remaining significant coefficients and their confidence errors are printed.

Mathematical models of ion-ozone seed treatment of grain crops are shown in table 4.

here:

$y_{ger}$  – germination, %;  
 $x_2$  – overpressure, at;  
 $s_y, s_{ag}$  – Root mean square deviation;  
 $F_r, F_{cr}$  – Fisher's Criterion;  
 $t_{cr}$  – Student Criterion.

Restrictions on the range of variation in the regime parameters of ion-ozone treatment of all the investigated cereal crops were as follows:

$$1 \text{ mln. unit/mg} \leq C_{i/o} \leq 15 \text{ mln. unit/mg}$$

$$13 \% \leq w \leq 20 \%; 10 \text{ min} \leq t_1 \leq 20 \text{ min}$$

The mathematical model for optimizing the modes of ion-ozone treatment of barley of the variety Baisheshek has this form:

*Seed properties:*

– objective function:

$$80 \leq y_1 = 132,50 - 2,50 \cdot w - 2,32 \cdot t + 0,129 \cdot w \cdot t, \% \leq 100 \rightarrow \max \text{ (Eq. 1)}$$

– restrictions on quality indicators:

$$85 \leq y_2 = 119,89 + 1,61 \cdot w, \% \leq 100 \text{ (Eq. 2)}$$

$$85 \leq y_3 = 117,57 - 1,43 \cdot w, \% \leq 100 \text{ (Eq. 3)}$$

*Physical properties:*

– objective function

$$1,0 \leq y_6 = 1,105, \text{ g/cm}^3 \leq 1,2 \rightarrow \max \text{ (Eq. 4)}$$

– restrictions on quality indicators:

$$12,0 \leq y_4 = 4,47 + 0,634 \cdot w, \% \leq 22,0 \text{ (Eq. 5)}$$

$$600 \leq y_5 = (62,86) \cdot 10 \text{ g/l} \leq 650 \text{ (Eq. 6)}$$

$$45,0 \leq y_7 = 16,55 + 1,59 \cdot C_{i/o} + 2,23 \cdot w - 0,0867 \cdot C_{i/o} \cdot w, \text{ g} \leq 65,0 \text{ (Eq. 7)}$$

#### *Biochemical properties:*

– objective function

$$5,5 \leq y_8 = 12,04 - 0,174 \cdot w, \% \leq 10,0 \rightarrow \max; \text{ (Eq. 8)}$$

– restrictions on quality indicators:

$$56,0 \leq y_9 = 62,67, \% \leq 75,0 \text{ (Eq. 9)}$$

$$28,0 \leq y_{10} = 33,01, \% \leq 35,0 \text{ (Eq. 10)}$$

here:

$C_{i/o}$  – ratio of ion concentration (units/cm<sup>3</sup>) to ozone concentration (mg/cm<sup>3</sup>), units/mg;  
 $P$  – overpressure (for cavitation treatment), ati;  
 $w$  – sample moisture before processing, %;  
 $t_1$  – processing time, min.  
 $y_1$  – germination energy, %;  
 $y_2$  – germination in 5 days, %;  
 $y_3$  – germination in 7 days, %;  
 $y_4$  – humidity after processing, %;  
 $y_5$  – nature, g/l;  
 $y_6$  – grain density, g/cm<sup>3</sup>;  
 $y_7$  – weight of 1000 grains, g;  
 $y_8$  – protein, %.  
 $y_9$  – starch, %;  
 $y_{10}$  – greenery index, ml.

The nature of the dependence of the energy of barley germination Baisheshek on the factors  $w$  and  $t$  is shown in Figure 4. The remaining dependencies of objective functions on the investigated factors, as follows from mathematical models, do not need graphical representation.

Using ion-ozone processing (IO), mathematical models were obtained for optimizing the technological regimes and quality indicators of barley of the Baisheshek variety. The results are shown in Table 5.

here:

$C_{i/o}$  – ratio of ion concentration (units/cm<sup>3</sup>) to ozone concentration (mg/cm<sup>3</sup>), units/mg;  
 $w$  – sample moisture before processing, %;

$t_1$  – processing time, min.

$y_1$  – germination energy, %;

$y_2$  – germination in 5 days, %;

$y_3$  – germination in 7 days, %;

$y_4$  – humidity after processing, %;

$y_5$  – nature, g/l;

$y_6$  – grain density, g/cm<sup>3</sup>;

$y_7$  – weight of 1000 grains, g;

$y_8$  – protein, %.

$y_9$  – starch, %;

$y_{10}$  – greenery index, ml.

The data in Table 5 indicates that there is no need for the nature of the dependence of the germination energy of Baisheshek barley on the factors  $w$  and  $t$  and the rest of the dependence of the objective functions on the factors studied.

Restrictions on the range of variation in the regime parameters of ion-ozone cavitation treatment of all the investigated cereal crops were as follows:

$$1 \text{ mln. unit./mg} \leq C_{i/o} \leq 15 \text{ mln. unit./mg}$$

$$1 \text{ ati} \leq P \leq 4 \text{ ati}$$

$$13 \% \leq w \leq 20 \%$$

$$10 \text{ min} \leq t \leq 20 \text{ min}$$

Taking into account the acceptable ranges of changes in the investigated factors ( $C_{i/o}$ ,  $P$ ,  $w$ , and  $t$ ), mathematical models for optimization of ion-ozone cavitation processing of grain are presented below.

The mathematical model for optimizing the modes of ion-ozone cavitation processing of barley of the variety Baisheshek has this form:

#### *Seed properties:*

– objective function

$$84 \leq y_1 = 113,95 - 0,929 \cdot w - 0,275 \cdot t, \% \leq 100 \rightarrow \max \text{ (Eq. 11)}$$

– restrictions on quality indicators:

$$86 \leq y_2 = 113,48 - 0,893 \cdot w - 0,200 \cdot t, \% \leq 100 \text{ (Eq. 12)}$$

$$88 \leq y_3 = 98,25 + 0,769 \cdot t - 0,0557 \cdot w \cdot t, \% \leq 100 \text{ (Eq. 13)}$$

#### *Physical properties:*

– objective function

$$1,0 \leq y_6 = 1,11, \text{ g/cm}^3 \leq 1,14 \rightarrow \max \text{ (Eq. 14)}$$

– restrictions on quality indicators:

$$12,0 \leq y_4 = 4,14 + 0,660 \cdot w, \% \leq 18,0 \text{ (Eq. 15)}$$

$$600 \leq y_5 = 627,3, \text{ g/l} \leq 650 \text{ (Eq. 16)}$$

$$47,0 \leq y_7 = 35,68 + 1,05 \cdot w, \text{ g} \leq 62,0 \text{ (Eq. 17)}$$

#### *Biochemical properties:*

– objective function

$$7,0 \leq y_8 = 11,59 - 0,167 \cdot w, \% \leq 11,0 \rightarrow \max \text{ (Eq. 18)}$$

– restrictions on quality indicators:

$$55,0 \leq y_9 = 62,49, \% \leq 67,0 \text{ (Eq. 19)}$$

$$28 \leq y_{10} = 33,78 - 0,121 \cdot C_{i/o} + 0,127 \cdot t + 0,0434 \cdot C_{i/o} \cdot P - 0,0321 \cdot P \cdot t, \% \leq 38 \text{ (Eq. 20)}$$

From the mathematical models, it can be seen that all the objective functions of barley have a simple character - the germination energy depends only on two factors (grain moisture and processing time), the density of barley grain does not change statistically (constant), and the mass fraction of the starch depends only on the moisture content of the grain. Therefore, the graphical dependence is presented only for the germination energy (Figure 5). It is seen that it inversely decreases with increasing barley moisture and the duration of its treatment.

The optimal modes and quality indicators of the grain of barley Baisheshek after ion-ozone cavitation treatment are shown in table 6.

here:

$C_{i/o}$  – ratio of ion concentration (units/cm<sup>3</sup>) to ozone concentration (mg/cm<sup>3</sup>), units/mg;  
 $P$  – overpressure (for cavitation treatment), at;  
 $w$  – sample moisture before processing, %;  
 $t_1$  – processing time, min.  
 $y_1$  – germination energy, %;  
 $y_2$  – germination in 5 days, %;  
 $y_3$  – germination in 7 days, %;  
 $y_4$  – humidity after processing, %;  
 $y_5$  – nature, g/l;  
 $y_6$  – grain density, g/cm<sup>3</sup>;  
 $y_7$  – weight of 1000 grains, g;  
 $y_8$  – protein, %;  
 $y_9$  – starch, %;

$y_{10}$  – greenery index, ml.

Table 6 indicates that in order to improve the seed and biochemical properties of Baisheshek barley, ion-ozone cavitation treatment should be carried out at  $C_{i/o} = 1$  million units/mg,  $P = 1$  at,  $W = 13\%$  and  $t = 10$  min. With the same values of  $C_{i/o}$ ,  $P$ ,  $t$ , physical properties will also improve, but grain processing should be carried out at grain moisture of 20 %.

To compare the quality of control (unprocessed) samples of the studied cultures and the optimal parameters obtained after their ion-ozone (IO) and ion-ozone cavitation (IOC) treatment.

Summary of the optimal indicators of the quality of barley after ion-ozone and ion-ozone cavitation treatment in comparison with control (unprocessed) samples are shown in Table 7.

here:

$y_1$  – germination energy, %;  
 $y_2$  – germination in 5 days, %;  
 $y_3$  – germination in 7 days, %;  
 $y_4$  – humidity after processing, %;  
 $y_5$  – nature, g/l;  
 $y_6$  – grain density, g/cm<sup>3</sup>;  
 $y_7$  – weight of 1000 grains, g;  
 $y_8$  – protein, %;  
 $y_9$  – starch, %;  
 $y_{10}$  – greenery index, ml.

Analysis of these tables showed that the optimum regimes of ion-ozone and ion-ozone cavitation treatment to improve the considered seed, physical, biochemical properties and the state of preservation of grain is the same, in the moisture content of the grain – optimal results were obtained when processing wet grain (20%). For seed, physical, biochemical, and state of preservation, the best results were obtained when processing dry grain (13%).

The full-factor planning of experiments of 2<sup>3</sup> and 2<sup>4</sup> degrees made it possible to obtain regression equations describing the change in the seed, physico-biochemical and physiological properties of grain crops from the influencing factors of ion-ozone and ion-ozone cavitation processing of grain and to identify priority grain indicators for constructing a linear and non-linear programming model with the indication of target and restrictive functions.

Integrated programming optimization models for individual varieties of grain crops made it possible to establish optimal

technological processing modes (IO and IOC) and increase achievable levels of seed, physico-biochemical, flour, baking, physiological properties, and their technological qualities for the intended purpose.

Thus, mathematical models have been calculated and developed that describe changes in the seed and technological properties of grain seeds during ion-ozone and ion-ozone cavitation preparation of grain seeds, which subsequently allow optimizing processing conditions. As a result, regression models were obtained based on  $2^3$  and  $2^4$  full-factor experts for the Baisheshek barley variety.

Photographs were taken of growing Baisheshek barley under experimental conditions. When growing crops, the treatment with electrically charged air particles was carried out in two versions: open and closed in the form of greenhouses during treatment with air ions with a duration of 25 minutes, and the results are shown in Figures 6-8.

The physical and biochemical studies aimed at increasing germination, vitality, and growth strength show a reasonably clear picture in terms of their final value. Phenological observations have shown that the effects of ion-ozone and ion-ozone cavitation treatment are triggered after 25-30 days, where the greatest tendency of the superiority of ion-ozone cavitation treatment is observed, ion-ozone follows, and the control, of course, significantly lags.

#### 4. CONCLUSIONS

Determining the strength of seed growth provides higher objectivity in assessing seeds by their ability to germinate and form seedlings. Along with a high growth force, seeds during germination formed seedlings with four and five roots and seedlings with three roots predominated in those variants.

Studies of changes in the seed properties and technological qualities of grain crops using ion-ozone (IO) and ion-ozone cavitation (IOC) processing of cereals into full-factor experiments  $2^3$  (8 experiments) and  $2^4$  (16 experiments) allowed to create the basis for the development of regression models to describe the change indicators of seed properties and technological qualities and in the future for the rational organization of equipment and technology of IO and IOC processing.

Ion-ozone treatment of seeds for sowing barley varieties and further cultivation with the treatment of plants with a stream of electrically charged air particles generally increase their yield, seed, and technological properties. The obtained data of these properties during ion-ozone treatment are much better compared to the traditional version, while there is an improvement in physical and biochemical parameters, and the seeds become more stable during storage, providing an increase in their safety.

The obtained results of the above properties during ion-ozone cavitation treatment (IOC) become better compared to traditional and ion-ozone treatment (IO). Moreover, indicators characterizing the studied properties of grain varieties in terms of their physical and biochemical properties and state of conservation have high potentials for their effective use in the production of grain products and meeting the requirements for preparing export batches of grain crops.

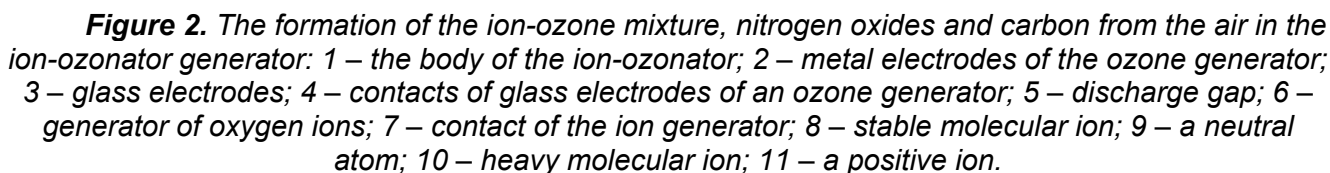

The developed mathematical models describe changes in the seed and technological properties of grain seeds during ion-ozone and ion-ozone cavitation preparation of barley seeds, and they can be used to optimize processing conditions.

**RESUMO**

O artigo discute as reservas de matérias-primas secundárias, fertilizantes orgânicos locais e ameliorantes (turfa, sapropel, fosfogesso, fosforitos, carvões de linhito, zeólitos, gipsita, calcário) na República do Bascortostão. O efeito do fosfogesso e do esterco de aves na fertilidade do solo e no rendimento da batata é estudado. O uso de gesso para melhorar o solo tem sido estudado e utilizado na agricultura e na restauração ambiental há muitos anos. A maior parte da literatura publicada é dedicada à influência do uso de gesso nas propriedades do solo e não no rendimento. O artigo apresenta os resultados de um experimento de campo sobre o uso de fosfogesso juntamente com resíduos de aves, com documentação detalhada de alterações na composição de microelementos dos solos, modo de precipitação e rendimento total após a fertilização. Os resultados do trabalho fornecido serão úteis na determinação das normas de aplicação de gesso; há também recomendações para pesquisas futuras sobre o uso de gesso para a melhoria do solo. A melhoria do rendimento pode ser o resultado de um efeito aditivo ou sinérgico; portanto, é altamente recomendável uma meta-análise de experimentos de gesso para melhorar as recomendações para o uso de gesso em vários ambientes. As taxas ideais de aplicação de matérias-primas secundárias são encontradas. O conteúdo do húmus do solo melhora e o rendimento da batata aumenta de 13,9 para 75,7 C/ha quando o fosfogesso é aplicado separadamente e em combinação com o esterco de aves. Existe o valor nutricional do esterco de aves, com os principais elementos como nitrogênio, fósforo e potássio. O fosfogesso é caracterizado com alto teor de estrôncio (14691 mg/kg) e elementos de terras raras (cério - 1358 mg/kg, praseodímio - 123,9 mg/kg, neodímio - 418,5 mg/kg, samário - 77,5 mg/kg, európio - 19,9 mg/kg, gadolínio - 58,9 mg/kg, térbio - 6,91 mg/kg e disprósio - 25 mg/kg). O conteúdo das formas totais de elementos no fosfogesso foi determinado por espectrometria de massa por plasma acoplado indutivamente (ICP-MS) usando um espectrômetro de massa VG Plasma Quad e Elan-6100.

**ABSTRACT**

The paper discusses reserves of secondary raw materials, local organic fertilizers, and ameliorants (peat, sapropel, phosphogypsum, phosphorites, lignite coals, zeolites, gypsum, limestone) in the Republic of Bashkortostan. The effect of phosphogypsum and poultry manure on soil fertility and potato yields is studied. The use of gypsum to improve soil has been studied and used in agriculture and environmental restoration for many years. Most of the published literature is devoted to the influence of the use of gypsum on soil properties and not on yield. The paper presents the results of a field experiment on the use of phosphogypsum together with poultry waste, with detailed documentation of changes in the microelement composition of soils, the mode of precipitation, and the total yield after fertilizing. The results of the given work will be useful in determining gypsum application norms; there are also recommendations for future research on the use of gypsum for soil improvement. The yield improvement may be the result of an additive or synergistic effect; therefore, a meta-analysis of gypsum experiments is strongly recommended to improve recommendations for the use of gypsum in various environments. The optimal application rates of secondary raw materials are found. The soil humus

content improves, and potato yield increases from 13.9 to 75.7 C/ha when phosphogypsum is applied separately and in combination with poultry litter. There is the nutritional value of the poultry manure, with the main elements as nitrogen, phosphorus, and potassium. Phosphogypsum is characterized with high content of strontium (14691 mg/kg) and rare earth elements (cerium – 1358 mg/kg, praseodymium – 123.9 mg/kg, neodymium – 418.5 mg/kg, samarium – 77.5 mg/kg, europium – 19.9 mg/kg, gadolinium – 58.9 mg/kg, terbium – 6.91 mg/kg and dysprosium – 25 mg/kg). The content of total element forms in phosphogypsum was determined by inductively coupled plasma mass spectrometry (IPC-MS) using a VG Plasma Quad and Elan-6100 mass spectrometer.

## АННОТАЦИЯ

В статье рассматриваются запасы вторичного сырья, местных органических удобрений и мелиорантов (торф, сапропель, фосфогипс, фосфориты, лигнитные угли, цеолиты, гипс, известняк) в Республике Башкортостан. Изучено влияние фосфогипса и птичьего помета на плодородие почвы и урожайность картофеля. Использование гипса для улучшения почвы изучалось и использовалось в сельском хозяйстве и восстановлении окружающей среды в течение многих лет. Большая часть опубликованной литературы посвящена влиянию использования гипса на свойства почвы, а не на урожайность. Мы предлагаем результаты полевого эксперимента по использованию фосфогипса вместе с отходами птицеводства с результатами изменения микроэлементного состава почв, количества осадков и урожая после внесения удобрений. Результаты нашей работы будут полезны при определении норм применения гипса и использованию гипса для улучшения почвы. Повышение урожайности в наших исследованиях может быть результатом аддитивного или синергетического эффекта, поэтому перед применением фосфогипса в различных средах рекомендуется предварительный его метаанализ. Найдены оптимальные нормы внесения вторичного сырья. Содержание гумуса в почве улучшается, а урожай картофеля увеличивается с 13,9 до 75,7 ц / га при применении фосфогипса отдельно и в сочетании с птичьим пометом. Существует питательная ценность птичьего помета с основными элементами, такими как азот, фосфор и калий. Фосфогипс характеризуется высоким содержанием стронция (14691 мг/кг) и редкоземельных элементов (церия - 1358 мг/кг, празеодима - 123,9 мг / кг, неодима - 418,5 мг/кг, самария - 77,5 мг/кг, европия - 19,9 мг/кг, гадолиний - 58,9 мг/кг, тербий - 6,91 мг/кг и диспрозий - 25 мг/кг). Общее содержание элементов в фосфогипсе было определено с помощью масс-спектрометрии с индукционной плазмой используя спектрометры VG Plasma Quad и Elan-6100.

**Ключевые слова:** *удобрение; органическое земледелие; фосфогипс; птичий помет; урожайность.*

## 1. INTRODUCTION

Soil is a living substance with a sanitary ecological function being one of the most important (Dobrovolsky and Grishina, 1985). The soil can process a large amount of foreign materials and convert them into humus substances useful to restore fertility. The soil systems are more adapted to process organic substances of animal and plant origin (droppings of wild birds, animals) into stable organomineral humus compounds due to their enzymatic mechanisms developed during the evolution (Nasir *et al.*, 2019; Szajdak and Simakina, 2008). However, this does not work the same for mineral fertilizers (Kiryushin, 2012; Willer and Kilcher, 2011).

The distinctive features of current farming systems are the prevention of soil degradation and the reduction of the risk of environmental violations in the production of agricultural products (Gabassova *et al.*, 2017; Khamaletdinov *et al.*, 2018; Surekha *et al.*, 2013). Improved

environmental performance of agriculture requires bringing it in line with the laws of fertility, addressing the issues of biodiversity conservation, adaptation to agroecological conditions, optimizing the ratio of natural and agricultural lands, creating an optimal infrastructure of agricultural landscapes taking into account energy and mass transfer (Kiryushin, 2012; Willer and Kilcher, 2011). It has now become evident that natural, biological technologies are the alternative to the chemical load on agriculture (Gelashvili *et al.*, 2002). Biotechnology uses the ability of microorganisms, worms, cell cultures, tissues, their constituent parts to synthesize compounds important for humans (Gukalov, 2009). At the same time, the soil accumulates carbon, nitrogen, potassium, phosphorus, and microelements, getting better regime and structure and less effect of toxic substances (Kiryushin, 2012, 2015). Biotechnologies can restore soil fertility as well as its productivity as a result of lower pesticide load, higher plant resistance to adverse environmental

conditions (Khaibullin *et al.*, 2018; Sokolov, 1975).

Organic farming is a system that uses organic sources to feed crops and biological sources to control pests and diseases. Biofertilizers are also essential components of organic farming. They stimulate plant growth, biological restoration of the soil and its natural fertility, protect against drought, and some plant diseases. Composting can play an essential role in solid waste management programs and can significantly reduce the amount of wastes in a landfill. Moreover, it saves resources and reduces soil pollution (Pathak, 2011; Surekha *et al.*, 2013).

The growing interest in more significant organic farming and agricultural production is due to the constant increase in prices for agrochemicals and energy sources, low utilization of mineral fertilizers by plants, significant soil nutrient losses, decreased product quality with intensive use of mineral fertilizers and pesticides. The total number of farms introducing biological methods of agriculture is growing by about 8,9% per year. Their area has grown from 15.8 million hectares to 37.2 million hectares worldwide over the past decade (Paull, 2011; Wai, 2007; Willer and Kilcher, 2011).

The soil can process significant amounts of foreign material into stable organomineral humus compounds to restore and improve the fertility of leached Chernozem and increase the productivity of cultivated crops. The need to develop effective methods of soil fertility recovery to create optimal conditions and increase the agricultural biocenoses productivity underlies the importance of this direction.

The goal of this work is to assess the efficiency in using secondary resources (wastes of the poultry industry and the production of mineral fertilizers) as the primary sources of organic substances and nutrients entering the soil.

## 2. MATERIAL AND METHODS

### 2.1. Experimental site

The experimental work was carried out by stationary field and laboratory-analytical methods. Stationary field studies were conducted on leached Chernozem (*Luvic Chernozems*) in the southern forest-steppe zone during the plantation of the Nevsky potato variety in 2015-2017.

Mainly, it was the experimental field of the Educational and scientific center of the Bashkir State Agrarian University, Russia. The sections of the field experiment had a width of 4–5, a length of 8–9 m, and a slope of 1–3°. A topographic survey (scale 1:100) in the international coordinate system (WGS) -84) and the Baltic elevation system with an interval between the contours of 0.1 m was performed to obtain more fundamental characteristics of the plots. The plots were leveled, equipped with sewage and water intake, bordered around the perimeter and separated from each other by earthen walls; On the arable land, plowing of slabs to a depth of 20 cm was practiced; the original vegetation cover of the deposit consisted of purple alfalfa (*Medicago sativa*) and meadow and weed plants: reeds (*Anthemisarvensis*), milk thistle (*Sonchus arvensis*), common wormwood (*Artemisia absinthium* L.) and field bindweed (*Convolvulus arven* L.). The soil was suitable for weakly leached and weakly weathered clay-clay-illuvial arable chernozem (*Luvic Chernozem* (*Clayic, Aric, Pachic*)). It was characterized by medium-deep humus horizons (AU + AU<sub>b</sub> 60 cm), average humus content, and slightly acid reaction. The aggregate state and porosity of the plow layer were evaluated as ideal; The water-resistance of the soil structure was high. The total amount of irrigation water was determined using rain gauges (5 sensors) installed around the periphery of the studied areas.

### 2.2. Sampling

The water permeability of the soil was determined by the cylindrical method (Vadiunina & Korchagina, 1986). Soil samples for determining the structural-aggregate composition and density were taken in layers of 0–10 and 10–20 cm in four repetitions. Samples were taken before, and after irrigation, soil moisture in the upper layer between irrigation was 15–20%, air temperature 20–25 °C; wind speed did not exceed 2 m/s.

### 2.3. Fertilizer application

After moldboard plowing and secondary tillage (harrowing), two plots of 0,1 hectares each were selected. The experiment scheme included a traditional farming system and variants to improve soil fertility: 1- control (without application); 2- Phosphogypsum, 5 t/ha; 3- Phosphogypsum, 10 t/ha; 4- Phosphogypsum, 20 t/ha; 5- poultry manure, 40 t/ha; 6-

Phosphogypsum+poultry manure, 1:10 ratio of 1:10, dose 40 t/ha.

#### 2.4. Laboratory analytical methods

Soil samples were selected based on the upper genetic horizons of the soil profile, laboratory and analytical studies were carried out using methods accepted in soil science. The total humus was determined by the method of I. V. Tyurin, soil moisture, and macronutrients (nitrogen, phosphorus, potassium) were detected according to the available guidelines for agrochemical indicators (Arinushkina, 1970; Vadiunina and Korchagina, 1986).

The content of total element forms in phosphogypsum was determined by mass spectrometry with inductively coupled plasma-ICP-MS on a VG Plasma Quad and Elan-6100 mass spectrometer under standard change conditions using imported reference samples in the laboratory of the Federal State Unitary Enterprise "All-Russian Research Institute of mineral raw materials named after N. M. Fedorovsky". The measurement error at the level of units and hundredths is no more than 15%. The device was calibrated with standard solutions containing a set of appropriate elements. The element concentration was based on the following: the analyzed solution was sprayed, the flow of argon brings it into a high-temperature plasma, where most of the atoms are ionized. Some of the ions formed in the plasma fall into a vacuum chamber, where they were accelerated and focused using ion lenses. Then the ion beam enters the inhomogeneous electromagnetic field of the quadrupole, where ions are spatially separated by weight. When scanning the electromagnetic field of the quadrupole, ions of a certain weight fell sequentially on the ion detector and were registered using electrical measuring devices. The received signals were proportional to the content of certain ions in the plasma, were processed using a computer system, and the analyses results were printed out.

Statistical processing of experimental data was performed using Microsoft Office Excel 2007 and SNEDECOR V. 5.80 software.

### 3. RESULTS AND DISCUSSION

Due to the sharp disparity in prices for agricultural products, and material costs for its production, the use of mineral fertilizers is sharply limited at present. There is much concern about

the reproduction of soil fertility. Having conducted an analytical analysis of the possible economically and environmentally beneficial ways to reproduce soil fertility, we figured it to be possible to use the available resources, which the Republic of Bashkortostan possesses.

Stocks of the secondary material resources, local organic fertilizers, and ameliorants are huge, but they are not used to the full (Khabirov, 2015). Some of them are practically not used (Table 1).

The Meleuz plant of mineral fertilizers has 11 million tons of phosphogypsum, which is practically not used. Phosphogypsum stacks occupy a large area and are a danger to the local ecological situation, although phosphogypsum is a valuable multi-component fertilizer. It is not actually applied to the soils of the Republic of Bashkortostan since there are no enough recommendations for its use. Poultry farms of the Republic of Bashkortostan collect hundreds of thousands of tons of poultry manure every year. For example, in storage facilities of the Poultry Production unit named after M. Gafuri, there about 500 thousand tons of high-quality turkey manure. We have taken the first steps to develop complex multi-component organic and mineral fertilizers based on phosphogypsum, and turkey manure, since the sources of raw materials are close to each other.

At the site where raw poultry manure of the M. Gafuri Poultry Production unit is stored, there is an unpleasant stinking smell. The manure mass contains much weed seeds, eggs and larvae of worms and flies, and a lot of microorganisms. Long-distance transportation of manure is not economically justified and requires a lot of equipment, labor, and money. However, waste is usually concentrated in small areas, which exacerbates its negative effect. As a result, the components of ecosystems located in the zone of large poultry farms are significantly transformed (Kiryushin, 2012; Gabassova *et al.*, 2017).

Manure processing can be a reasonable solution to this situation. In particular, high-temperature drying turns manure into a decontaminated, highly concentrated fast-acting organic fertilizer with favorable physical properties, devoid of smell, and germinating weed seeds. The value and nutritional properties of dry manure will be determined by the chemical composition of the raw materials taken for processing (the original raw manure) and the drying technology. However, before

recommending the final product (dry manure) for use as a fertilizer, it is necessary to determine its potential fertilizing properties and assess its safety for environmental components.

The nutritional value of manure, like any other fertilizer, is determined by the content of the main elements of plant nutrition as nitrogen, phosphorus, and potassium (Table 2).

The nitrogen content in the manure taken for processing is low. One ton of this organic fertilizer can introduce just 6.3 kg of nitrogen into the soil. It is due to both the high moisture content of the source material and the relatively low concentration of the element per dry substance. As a rule, the nitrogen content is reduced during the drying process for its ammonia form that rapidly evaporates under thermal action.

Poultry manure is evenly applied to the fallow once per crop rotation with further placement to accelerate the transformation process.

Such important plant nutrition elements as calcium, phosphorus, and sulfur make phosphogypsum an attractive fertilizer (Davari *et al.*, 2002). Currently, the average level of the nutritive efficiency of this industrial waste is no more than 2.0 %, although in previous years it was about 2.5 million tons/year (over 10% of the current output) In agricultural production phosphogypsum can be used for the following purposes:

- for improving physical soil properties;
- for the optimization of plant nutrition with calcium, sulfur, silicon, phosphorus and trace elements;
- for soil reclamation (Tayibi *et al.*, 2009).

For Chernozem soils, the use of phosphogypsum is even more in demand, since the content of phosphorus is one of the main limiting factors.

According to literature data, recommended doses of phosphogypsum vary from 2 to 35 t / ha depending on the type of soil, crops to be grown, method and type (continuous or selective) of application and fertilizers to be used (Kotova *et al.*, 2002)

The analysis of phosphogypsum (waste from the Meleuz mineral plant) shows a high content of strontium (14691 mg/kg) and rare earth elements (cerium-1358 mg/kg, praseodymium – 123.9 mg/kg, neodymium – 418.5 mg/kg, samarium – 77.5 mg/kg, europium

– 19.9 mg/kg, gadolinium – 58.9 mg/kg, terbium-6.91 mg/kg and dysprosium 25 mg/kg), which is not typical for soils and rocks of the southern Urals. The content of oxides in phosphogypsum is shown in Table 3.

Taking into account the chemical composition of phosphogypsum, its direct and indirect influence on soil fertility, the following experimental scheme was developed:

- control
- phosphogypsum, 5 t / ha;
- phosphogypsum, 10 t / ha;
- phosphogypsum, 20 t / ha;
- poultry manure, 40 t / ha;
- phosphogypsum+poultry manure, 1:10 (40 t/ha)

Based on the current situation, a sharp decrease in the content of organic matter in the soil, the paper presents the content of humus.

When conducting experimental research, there were changes in the humus state of the soil. When applying pure phosphogypsum, there was no significant effect on the content of humus in the soil. However, when applying it together with poultry manure, there was an increase in the humus content by 0.34%. Maximum values of 7.02-7.10 % were observed when applying pure poultry manure at a dose of 40 t / ha (Table 4).

Potatoes of the Nevsky variety were grown on the experimental plots for three years. In the first year of studies, the maximum increase (307C/ha) was observed in the variants with 40 T/ha of introduced poultry manure. The use of phosphogypsum in pure form also increased from 22.2 to 91.7 C/ha with higher rates of application (Table 5). There was a higher yield at 137 C/ha in the variant with applied manure and phosphogypsum compared to the control one. As scientists claim (Baibekov *et al.*, 2012; Belyuchenko and Muravyov, 2009), at the phosphogypsum application rate of 5 t/ha, 100-130 kg of P<sub>2</sub>O<sub>5</sub> in digestible form can enter the soil. It covers the costs of agriculture significantly for phosphogypsum transportation and introduction.

The second year of research (2016) was dry, and the soil moisture content was 140 mm. It affected the yield of potatoes. The yield development by variants remained in the same sequence as the first year of research (Zinkovskaya, 2010). It is established that the phosphogypsum application at the rate of 2-4

C/ha can meet the needs of agricultural plants in nutrients and increase crop yields.

In 2017, the largest increase was observed on the variants with pure poultry manure and in a mixture with phosphogypsum, 75.7, and 63.2, respectively. The aftereffect of phosphogypsum provided a significant increase in all years of research. The application of a higher rate of phosphogypsum resulted in lower potato yield. A negative impact on the growth and development of plants led to potato inhibition. There were no toxic metals and nitrates in potato tubers in examining.

The current scientific papers provide similar ways to improve the agrochemical qualities of the soil, neutralize the reaction of the soil solution medium (Pavani and Shanmugam, 2019). Alternatively, to suppress the intake of heavy metal salts in plants (Sattar *et al.*, 2019).

However, an approach comparable to ours, involving the simultaneous synergistic use of phosphate gypsum with poultry waste, is relatively rare (Xue *et al.*, 2020).

Also, more often the mechanism of the positive effect on the crop is not appropriately discussed, and it is difficult to translate the improvement of individual soil qualities in connection with the improvement of the yield, despite the obviousness of this connection, the fact is that it is difficult to accurately determine the positive effects of the use of gypsum, which are responsible for the increase in yield because in the soil there are often many simultaneous physical and chemical changes. Improving yields may result from the additive or synergistic effect of each of these potential changes. Besides, these potential changes, no matter how different they may seem, also differ depending on the crop, soil type, and precipitation regime (Zoca and Penn, 2017).

Taking into account the chemical composition of phosphogypsum, research variants with different application rates, climatic conditions for three years provide reliable data on their impact on crop yields.

The problem of heavy metals in soils is relevant for agriculture, scientists Santos *et al.* (2006), Davari *et al.* (2012), Alloway (1990), and Mineev (1990) point out the possible accumulation of toxic metals in the soil as a result of the phosphogypsum application. Nevertheless, the authors found no significant changes in the natural levels of heavy metals if ameliorant is introduced at recommended rates directly after

the phosphogypsum application as well as in long biogeosystem sequences. Moreover, it was shown in the work of Sattar *et al.* (2019) that the use of gypsum together with poultry waste could contribute to the reduction of heavy metals in agricultural products, even at high levels of heavy metal charging of the original soils (before the application of gypsum and poultry waste).

In addition, the essential role of phosphogypsum as a fertilizer is that it has other macro and microelements in its composition. When applied to the soil in small rates, it does not have a harmful effect and, therefore, can serve as a mineral supplement (Bauer *et al.*, 2019). Another component of the fertilizer offered by the authors is poultry waste, having been widely used as a fertilizer, the subject of many papers for a long time (Szogi *et al.*, 2019). Thus, the first results of studies have shown the phosphogypsum efficiency applied both separately and in a mixture with poultry manure.

#### 4. CONCLUSIONS

The application of phosphogypsum and poultry droppings in pure form and a mixture is characterized by environmental safety. There is a high potential fertilizing value and expediency of applying secondary resources as organic fertilizers. When applied to the soil in all ratios and rates, phosphogypsum and poultry manure improve the humus state, significantly increase the yield of potatoes from 13.9 to 75.7 C/ha. Meanwhile, potatoes do not contain toxic elements and nitrates exceeding the MPC values.

**RESUMO**

O problema de preparar produtos de petróleo de alta qualidade é que produz água para reutilização e injeção no reservatório em condições de capacidade limitada das instalações. Essa é uma questão relevante no setor de petróleo e gás. Assim, o objetivo desta pesquisa foi desenvolver uma abordagem para a justificativa das decisões de projeto durante a reconstrução da Unidade Preliminar de Descarga de Água. O artigo considera a questão da modelagem de soluções de projeto para a reconstrução da unidade preliminar de descarga de água (região de Perm) com uma unidade móvel. As principais tarefas industriais são reduzir o corte de água do produto e o volume de bombeamento de lastro na Unidade de Preparação de Óleo (OPU) para fornecer a qualidade da água de fundo para injeção na formação atendendo aos requisitos da norma industrial. A instalação móvel é um desenvolvimento inovador e possui todo o equipamento necessário para recriar o processo de produção da preparação de produtos de poço em uma escala de aproximadamente 1: 100. Os resultados da simulação do processo de produção do poço mostraram que pode ser alcançado 1% com aquecimento a 30°C na injeção dos desmulsificadores SNPH-4880, STH-9. O método complicado mostrou uma dependência funcional e estável dos indicadores de temperatura e qualidade do processo na presença de um desmulsificador. Durante os testes de bancada foram encontrados valores de indicadores tecnológicos que proporcionaram a redução do volume de bombeamento de lastro em uma média de 5-6%. Estudos de amostras de água da saída da unidade móvel mostraram os melhores resultados ao testar o STH-9. Os resultados obtidos são de grande importância prática, e o método e o equipamento móvel especial proposto no artigo podem ser usados em qualquer planta de produção de tratamento de óleo.

**Palavras-chave:** refino de petróleo, refino de águas profundas, produção de poços, instalação móvel, emulsão de água e óleo.

**ABSTRACT**

The problem with preparing high-quality petroleum products is that it produces water for reuse and injection into the reservoir under conditions of limited facility capacity. This is a relevant issue in the oil and gas sector. Thus, the objective of this research was to develop an approach to justify project decisions during the reconstruction of the Preliminary Water Discharge Unit. The article considers the issue of modeling design solutions for the restoration of the preliminary water discharge unit (Perm region) with a mobile unit. The main industrial tasks are to reduce the water cut of the product and the volume of ballast pumping in the Oil Preparation Unit (OPU) to provide the quality of the background water for injection in the formation meeting the requirements of the industrial standard. The mobile installation is an innovative development and has all the necessary equipment to recreate the production process of the preparation of well products on a scale of approximately 1: 100. The results of the simulation of the well production process showed that it could be achieved 1 % with heating at 30°C in the injection of demulsifiers SNPH-4880, STH-9. The complicated method showed a functional and stable dependence on the temperature and quality indicators of the process in the presence of a demulsifier.

During bench tests, values of technical indicators were found that reduced the volume of ballast pumping by an average of 5-6%. Studies of water samples from the outlet of the mobile unit showed the best results when testing the STH-9. The results obtained are of great practical importance, and the method and the special mobile equipment proposed in the article can be used in any oil treatment production plant.

## АННОТАЦИЯ

Проблема подготовки высокого качества нефтепродуктов заключается в том, что в процессе образуется попутно добываемой вода для повторной использования и закачки в пласт в условиях ограниченных производственных мощностях. Это актуальная проблема в нефтегазовой области. Таким образом, цель этого исследования состояла в том, чтобы разработать подход для обоснования проектных решений по реконструкции установки предварительного сброса воды. В статье рассматривается вопрос моделирования проектных решений для восстановления работы установки предварительного сброса воды (Пермский край) с использованием мобильной установки. Основными производственными задачами являются снижение обводненности подготовленной продукции, уменьшение объема балластных перекачек на установке подготовки нефти (УПН), а также доведение качества подтоварной воды для закачки в пласт до требований отраслевого стандарта. Мобильная установка является инновационной разработкой и обладает всеми необходимым оборудованием для воссоздания производственного технологического процесса подготовки скважинной продукции в масштабе примерно 1:100. Результаты моделирования процесса подготовки скважинной продукции показали, что возможно достичь обводненность 1% при нагреве до 30°C в присутствии деэмульгаторов СНПХ-4880, СТХ-9. Комплексный метод на показал устойчивую функциональную зависимость температуры процесса и показателей качества в присутствии деэмульгатора. В ходе стендовых испытаний установлены диапазоны технологических показателей, при которых снизился объем балластных перекачек, в среднем, на 5-6%. Исследования проб воды по выходу из мобильной установки показали наилучшие результаты при испытании СТХ-9. Полученные результаты имеют важное практическое значение, а предложенные в статье метод и специальное мобильное оборудование может быть использовано на любой производственной установке подготовки нефти.

**Ключевые слова:** *подготовка нефти, подготовка подтоварной воды, скважинная продукция, мобильная установка, водонефтяная эмульсия*

## 1. INTRODUCTION:

To refine oil and wastewater, there is a regular need for technologies and technical means to be used and to improve the quality of the final product up to the relevant standards, regulated by the state authorities and regulatory documentation of oil and gas companies. There is no detected strictly defined combination of methods and technologies in industry practice to bring the quality of products to the commercial standards or standards of a company within the terms of physical and chemical properties diversity and variable composition of the crude oil (Kokal, 2002). Therefore, there is a need for oil and gas companies to test the most appropriate and effective methods regarding the refining of oil and wastewater per each area facility. This question becomes particularly relevant as the current time technology of refining at the area facility in the short term will not be sufficient, which will require operational changes in the technological process (Kokal, Wingrove, 2000). Any change of procedure of the area facility requires a significant investment (time, administrative, finance) and,

ultimately, might be technologically and economically feasible (Marquez-Silva, 1997). The results of laboratory modeling of the process regarding the refining are often turned to be estimated due to researching within the conditions to be different from the real (Tronov, 1977).

Increasing interest is received by mini- and micro-installations, the use of which is aimed at solving a specific problem within an industrial facility (Lekomtsev, Ilyushin, *et al.*, 2018). Laboratory studies performed on model samples, when well production has complex compositions and properties, become uninformative (Ilyushin, Usenkov *et al.*, 2017). The results of the studies often do not correlate with the actual situation in production (Tretyakov, Mazein, *et al.*, 2017). The current trend in the refining of downhole products is minimizing the size of the equipment with an increase in their level of manufacturability (Bahadori, 2014), as well as the transition from laboratory research to field tests (Li, Wengerter, *et al.*, 2016). This opinion proves the need to create a site (testing ground) for testing modern scientific methods and technologies and adapting

theoretical studies to the existing practice (Lekomtsev, Ilyushin, 2016). The way out is the creation of mobile units (The Canadian Association of Petroleum Producers, 2014).

A disadvantage of the known studies is the lack of a systematic approach and the corresponding technology for carrying out bench (field) testing of techniques for improving the quality of the preparation of tank oil and water for injection into the reservoir. Based on the Scientific-educational Centre for Geology and the Development of Oil and Gas Fields of the Perm National Research Polytechnic University, there is a unit created allowing to simulate different technological modes onto the current facility of refining without affecting the primary process (Tretyakov, Usenkov, *et al.*, 2016).

The principle of the unit is the destruction of Water-Oil Emulsion (WOE) by traditional and new technologies that are available at industrial facilities (Rzayev, Rasulov, 2013). Modern ideas about the stability of water-oil emulsions are concentrated in the theory of Deryagin-Landau-Fairway-Overbek (DLFO theory) (Deryagin, 1986). According to the method, the formation of structural-mechanical protective layers at the interphase boundaries is decisive importance in ensuring the stability of a WOE (Salager, 1990). Resistant layers can resist deformation and destruction and can "heal" defects arising from the contact of particles of the dispersed phase (the wedging effect of the Rebinder). Three stages determine the staging of the process of destruction of a WOE. For each stage, it is used technologies that are characterized by different efficiency and manufacturability (Zhang, 2010). The main ones are the use of chemical reagents, coalescing nozzles, magnetic, electric, and acoustic impact (Wallau, Schlawitschek *et al.*, 2016), heating (Schubert, Brandner, 2001), centrifugation and sedimentation with specific equipment and materials (Wang, 2016).

The developed unit has all the necessary equipment to recreate the production process of refining well products on a scale of approximately 1: 100. Due to this, in real-time, it is possible to assess the current and future possibilities of the refining facility when changing volume and composition crude oil production. It has the potential to allow to predict the product quality for several years ahead in the future.

The main practical value of the unit is the approbation of projects for the modernization of industrial plants and the rationale for investment costs for the purchase of equipment and the

construction of additional facilities. The article considers the issue of assessing design solutions for the reconstruction of a Preliminary Water Discharging Unit (PWDU) using a developed mobile unit in the Perm region (Russia). The aim of technological reconstruction of the area facility was the bringing of oil quality to the conformity of group 3 under Russian Government Standard requirements (GOST 51858-2002) regarding the content of water to reduce ballast pumpings up to Oil Preparing Unit (OPU) and to improve the quality of produced water (SSP – 15 mg/L; oil products – 15 mg/L).

The target of field treatment of crude oil is to reduce the resistance of WOE, to their disintegration, and to degrade the SSP and oil ratio within the wastewater (Tumanyan, 2000). To disintegrate the WOE, the most important aspect is the process of Armoured Shells (AS) removing of Emulsified Water Droplets (EWDs) and the separation of oil and water into separate phases (Nebogina, 2010). WOE stability is a critical factor regarding the disintegration of oil and water mixture and characterizes the ability not to be exfoliated for oil and water within a time specified. The factors greatly influence a drop AS stability (kinetic and aggregative) within the emulsion as following: coagulation and fragmentation of drops within a turbulent flow; disperse composition; physical and chemical properties of natural emulsifiers forming armored shells; the double emulsion layer presence on EWDs; the temperature of miscible liquids (oil and water); specific consumption of demulsifier; the pH of the reservoir water emulsified (Sakhabutdinov, Kosmacheva *et al.*, 2007). Also, one of the methods of water refining is electrocoagulation. Electrocoagulation is a progressive technological direction for getting rid of water from polluting substances by cleaning it in an electrolyzer with soluble electrodes. When an aqueous solution is found under the influence of a constant electric field, coarse impurities are destroyed, colloidal contaminants are aggregated, which stimulates the process of phase separation and water purification. The method of electrocoagulation of water shows excellent results in the refining of industrial water from finely dispersed organic monomers and polymers, emulsions, and refined products. It is useful in ridding water solutions of excess phosphates and chromates (Tetreault, 2003).

The purpose of this work was to develop an approach to the justification of design decisions during the reconstruction of the Preliminary Water Discharging Unit and select the necessary

equipment to reduce the water content of products refined. Also, it is aimed to decrease the number of ballast pumpings onto OPU, as well as bringing the quality of the produced water to be injected into the formation up to the requirements of Industrial Standard (IS-39-225-88).

During the research and pilot tests, the following tasks were solved:

- the confirmation of the technological scheme of the facility;
- the determination of temperature mode of refining;
- the selection of reagent-demulsifier from the number of recommended ones due to the results of laboratory tests.

## 2. MATERIALS AND METHODS:

### 2.1. The description of the mobile unit

The mobile well production preparing unit (MU) provides a core technology for oil refining (regarding the Russian government standard GOST 51858-2002): demulsification (dehydration), desalting, purification from mechanical impurities, oil stabilization (hot separation). According to this standard, oil is divided into three groups depending on the value of this parameter. Refining of wastewater used for flooding oil fields (regarding the Industrial Standard IS 39-225-88) – removal of oil products and Solid Suspended Particles (SSP). Due to mobility, the unit allows executing the refining of oil and water onto the well cluster sites with their low capacity of the product pumped without capital construction and arrangement of the area facility (Figures 1a and 1b). The mobile well production preparing unit technical characteristics are represented in Table 1. The PWDU existing and technological design schemes are shown in Figures 2a and 2b.

Under the technological project scheme of refining, the products shall come into the BE-2 container, which is used as a two/three-phase separator with its possibility of separating and discharging of formation water. From BE-2, the liquid separated from the gas under the pressure of 0.2-0.25 MPa is supplied to the pump intake of inner pumping P-1,2, which pumps the pressure up to 0.45 MPa, and feed the fluid into the heating block, consisting of two heaters H-1,2, which provides the liquid heating up to 40-45 °C. The heated flow past the heaters is fed to the OG-1 oil sumps, 2, where the thermochemical process of

oil dehydrating at a pressure of 0.3 MPa is performed. The dehydrated oil with its water content of up to 3 % is supplied into the BE-3 buffer tank. From BE-3 via the pump of oil external transporting through the oil metering unit, it is periodically pumped out onto the OPU. The gas separated in the process is sent to the gas turbine unit and is used as an energy source for heating the incoming raw materials. The content of sulfur-containing volatile compounds is low; therefore, associated petroleum gas is used without preliminary treatment.

Under the current scheme, the mobile unit was connected prior to the BE-2 serving as a buffer-degasser (E-1 in the MU). The modeling of piping the heaters was implemented by the heating system consisting of a heat exchanger, the H-4 pump, and the E-4 tank with the heaters. The E-5 horizontal type unit was consistent with the oil-settling tanks OG-1, 2. The products from the E-5 output were supplied into the drainage system. Within the field activities onto the mobile well production preparing unit prior to the maintenance, the demulsifier was brought into. To keep the experiment pure, the feeding of the demulsifier at the facility was not executed.

The properties of oil feeding into the PWDU are represented in table 2. Crude oil has an average viscosity, high gas factor, and is highly asphaltenic (Vyatkin, Kochnev, *et al.*, 2017).

### 2.2. The calibration and testing of the mobile unit

The calibration of the mobile unit prior conducting the simulation was to define the operating parameters (flow, pressure, temperature) under which the quality parameters (water content within the oil, chlorinated salts, mechanical impurities) of the mobile well production preparing unit output product and the refining facility were corresponding. The mobile unit performed the calibration mode past a series of experiments with regard to compliance of well products time spent within technological devices while ensuring the performance indicators as following (Table 3).

The water content at the outfeed of the bench (MU) and field installations is equal to 2%. The indicators of formation water quality have their differences, and the SSP content past the stand is above the field data, the oil content in water is lower than within the field facility. This fact indicates the high velocity of water discharging and capturing a more significant number of solid particles within the flow. The consumption rate at the time of the recording mode exceeded the

estimated per 53%. The increased content of oil products in the water at the outfeed from the production facility in comparison with the bench data is associated with the process temperature, which at the time of the experiment differed per 3 °C.

When increasing the flow rate of oil up to 0.76 m<sup>3</sup>/h (corresponds to 88 m<sup>3</sup>/h at the PWDU), the water content is risen sharply at the outfeed up to 18%, and the water quality worsens: SSP – 76 mg/l; oil products – 159 mg/L. Thus, the mobile well production preparing unit calculated mode fully describes the technological process of the PWDU.

### 2.3. The experimental-industrial testing

The modeling of advanced technological scheme past establishing a calibration mode of operation was performed under the rates calculated below.

The consumption of oil within the mobile well production preparing unit when testing is selected based on the equil time of treatment into operating volumes of OG-1, 2 at the PWDU and the E-5 tank installed on Mobile Unit:

$$Q_{MWPPU} = Q_{PWDU} \frac{\frac{L_{liq\ E-1}}{d_{E-1}} V_{E-5}}{V_{OG-1\ perf} + V_{OG-2\ perf}} = 0.22 \frac{m^3}{h} \quad (\text{Eq. 1})$$

Where  $V_{nom\ E-1}$  – the E-5 nominal volume – 1.6 m<sup>3</sup>;  $L_{liq\ E-1}$  – the liquid level – 740 mm;  $d_{E-1}$  – the E-5 diameter – 800 mm;  $V_{OG-1\ perf}$ ,  $V_{OG-2\ perf}$  – the operating volumes of OG-1, 2 – 100 m<sup>3</sup>,  $Q_{PWDU}$  – the pumping of oil from PWDU – 720 m<sup>3</sup>/day or 30 m<sup>3</sup>/h; daily water injection under the PWDU – 200-220 m<sup>3</sup>/day 8.3-9.2 m<sup>3</sup>/h; the ratio of oil pumping out/water pumping out – 27.8-30.6%.

To ensure the time of degassing of products input into the Mobile Unit, corresponding to a PWDU, the working volume of the E-1 should be:

$$V_{E-1} = V_{BE-2\ nom} \frac{L_{liq}}{L_{nom}} \frac{Q_{MU}}{Q_{PWDU}} = 0.82 m^3 \quad (\text{Eq. 2})$$

Where  $L_{liq}$  – the fluid level within the BE-2 – 1.9 m,  $L_{nom}$  – the nominal level within the BE-2 – 3.4 m. The fluid level in E-1 will be:

$$L_{liq\ E-1} = L_{nom\ E-1} \frac{V_{E-1}}{V_{nom\ E-1}} = 0.94 m \quad (\text{Eq. 3})$$

The consumption of water within the mobile well production preparing unit is regulated regarding the interface level in the E-5 at around

280-350 mm and, on average,  $Q_{MU(v)} = 0,076 m^3/h$ , which is 30% of the pumping volume of oil.

When conducting the field tests, the technological standards met the calculated values accordingly. Before the pilot tests on a mobile unit for model samples of emulsions, demulsifiers were selected. The most effective were brand demulsifier SNPH-4880, SNH-4114, STH-9 with the consumption of 70 g/ton. Demulsifiers showed the highest rate of emulsion separation; therefore, they were selected for field tests. Within the modeling process, it was succeeded to heat the products up to 30 °C in connection with the frequency of fluid intake because of the presence of the cork of the pumping mode till the PWDU and high velocity of the liquid phase flowing under images.

### 3. RESULTS AND DISCUSSION:

The results of the process modelling on refining of well production show that under the existing volumes of crude oil feeding, the refined oil pumping to the OPU and time and sediment term, it was enabled to reduce the water content u to 1% when heated to 30 °C in the presence of demulsifiers SNPH-4880, STH-9 (Figures 3 and 4).

The quality of oil refining onto the PWDU under the current scheme is not regulated and the water content at the outfeed of the installation varies from 2 to 10%. The proportion of the fluid fed at the OPU is 8.6%. The reducing and maintaining the water content up to 3% will decrease the daily volume of ballast pumping more than 40 m<sup>3</sup>.

The studies of water samples at the mobile well production preparing unit output have shown their best results within the testing of the STH-9. It is clear from Figures 3 and 4 that the synergistic effect of heating and chemical reagent supplying is decreased under the process temperature increasing. This is due to the high emulsion stability and the strength of armored shells of small droplets within the dispersed phase, requiring higher energy to perform its disintegrating (Zlobin, 2015). Besides, the size of the particles remaining in suspension under the flow temperature increased is not involved in the process of sedimentation and put away with water flow. The limitations on the effectiveness of thermo-chemical and gravitational processes of water refining are estimated at up to 45 °C for the given conditions (Figures 3 and 4). The bench tests, together with the results of sewage samples analysis, represent stable, functional dependence

of the process temperature and the quality parameters under the action of the demulsifier. They are ensuring the temperature of the refining process up to 37-40 °C evidences the fulfillment of the industrial standard requirements regarding the SSP and oil content within produced water.

In this field research, the similarity method is used to study the effect of destruction WOE and application study results to the real industry (Yemelyanov et al., 2019). This section discusses the technique of modeling crude oil refining with a developed mobile unit.

#### 4. CONCLUSIONS:

Thus, within the course of bench tests regarding the modeling of the refining process at the pilot mobile unit, the effectiveness of the PWDU designed technological scheme has been approved. According to the results of the studies conducted, it is possible to conclude the following:

1. The new product developed – mobile well production preparing unit – is industrially applicable and has shown its high convergence of scalable technology.
2. The proposed approach regarding the transition from the laboratory modelling to the field testing within a facility real conditions allows to increase the reliability of the results obtained and to justify the design decisions.
3. The ranges of technological parameters onto an area facility are set, under which it is possible to reduce the volume of ballast pumping an average of 5-6%.

The dependence of the wastewater quality indicators is set, based on the design scheme of an area facility depending on the process temperature and the demulsifier brand. The calculated boundaries per the heating temperature of the well production in the range of 37-40 °C to meet the requirements for commercial water quality up to the requirements of industry standards have been defined.

## RESUMO

A abordagem de aprendizado CTEM (Ciência, Tecnologia, Engenharia e Matemática) integra quatro disciplinas, a saber, ciência, tecnologia, engenharia e matemática na resolução de problemas da vida cotidiana e no fornecimento de muitas experiências de aprendizado aos alunos. Este estudo teve como objetivo analisar o interesse profissional no campo de CTEM para futuros professores indonésios de Matemática e Ciências Naturais (MIPA), estudando os padrões de relacionamento entre fatores, níveis de preferência e quais fatores o influenciam. A amostra da pesquisa foi de 300 futuros professores do MIPA na Faculdade de Formação e Educação de Professores da Universidade de Lampung. Este trabalho envolveu várias etapas como (1) adaptação e transliteração dos instrumentos de interesses de carreira STEM com base em fontes da literatura, (2) análise da validade do conteúdo com base no julgamento de especialistas, (3) disseminação de ferramentas para amostras de pesquisa e (4) avaliação de resultados de pesquisa, avaliação bivariada correlações e o nível de preferência de interesse. Os dados obtidos foram analisados estatisticamente utilizando técnicas de análise fatorial exploratória e confirmatória, análise de confiabilidade e variância e correlação produto-momento de Pearson. Os resultados da pesquisa mostraram que as informações referentes aos itens do questionário foram agrupadas em quatro fatores: atitude na carreira de engenharia, atitude na carreira em matemática, atitude na carreira em ciências e atitude na carreira em tecnologia com fatores de carga que variando de 0,575 a 0,848. Todos esses fatores foram capazes de explicar a atitude profissional da CTEM na soma de 62,43%. A atitude profissional em ciências e matemática é a preferência dominante para os futuros alunos de professores de Matemática e Ciências Naturais terem uma carreira no futuro. Além disso, os instrumentos utilizados são válidos e confiáveis para serem usados para analisar as atitudes profissionais de CTEM nos candidatos a professores de Matemática e Ciências Naturais.

**Palavras-chave:** *Interesses de carreira CTEM, candidatos a professores do MIPA, Universidade de Lampung.*

## ABSTRACT

STEM (Science, Technology, Engineering, and Math) learning approach integrates four disciplines, namely science, technology, engineering, and mathematics, in solving everyday life problems and giving many learning experiences to students. This study aimed to analyze career interest in the field of STEM for prospective Indonesian Mathematics and Natural Sciences (MIPA) teachers, studying the patterns of relationships between factors, preference levels, and what factors influence it. The research sample was 300 prospective MIPA teachers at the Faculty of Teacher Training and Education, Lampung University. This work involved several stages as (1) adapting and transliterating STEM career interests instruments based on literature sources, (2) analyzing content validity based on expert judgment, (3) spreading tools to research samples and (4) evaluating research data results, assessing bivariate correlations, and the level of interest preference. The data obtained were analyzed statistically using exploratory and confirmatory factor analysis techniques, reliability and variance analysis, and Pearson product-moment correlation. The research results showed information regarding the items in the questionnaire were grouped into four factors, namely engineering career attitude, mathematics career attitude, science career attitude, technology career attitude with loading factors ranging from 0.575 to 0.848. All these factors were able to explain the career attitude of STEM to the sum of 62.43%. The science and mathematics career attitude is the dominant preference for prospective students of Mathematics and Natural Sciences teachers to have a career in the future. Furthermore, the instruments used are valid and reliable to be used to analyze

**Keywords:** *STEM career interests, MIPA teacher candidates, Lampung University.*

## 1. INTRODUCTION:

STEM education is a learning approach that integrates four disciplines, namely science, technology, engineering, and mathematics, to solve problems in everyday life (Lin *et al.*, 2015; Jurdak, 2016; Shahali *et al.*, 2016; Tsai *et al.*, 2017; Gullen, 2018; Thibaut *et al.*, 2018; Chai, 2019). The learning curricula in several developed countries starting from elementary school to tertiary level nowadays have adopted the STEM approach because it is believed that this approach can provide a lot of learning experiences to students (Stohlmann, 2011; Pinnel, 2013; Barrak and Assal, 2018; Garner *et al.*, 2018; Roberts *et al.*, 2018; Bennett and Saunders, 2019; Morris *et al.*, 2019; Tytler *et al.*, 2019; Wu *et al.*, 2019). The continued application of the STEM approach in the learning process is believed to be able to shape and strengthen student character as a problem solver who is better, independent, innovative, inventive, creative, logical thinker, critical, and technology literate (Wells, 2019; Ibáñez, and Delgado-Kloos, 2018; Morrison, 2006). Moreover, STEM education positively impacts students' attitudes and interests in school (Bragow, Gragow and Smith, 1995), motivates students to learn (Guthrie, Wigfield and Von Secker, 2000) and improves student learning achievement (Hurley, 2001). Compared to teaching four disciplines as separate and discrete subjects, STEM integrates these disciplines into a cohesive paradigm based learning based on real-world applications (Hom, 2014).

Recently, the demand for a workforce well educated in science, technology, engineering, and math (STEM) is growing to stimulate economic growth and enhance innovation. The positive impact of the STEM approach to the learning process should be able to influence and enlarge the interest of students who will graduate vocational schools or students who will graduate from undergraduate to continue their education and/or have a career in the STEM field. However, many countries in the world face difficulties in carrying out the task of recruiting more people into science, the technology industry, engineering, and mathematics (STEM) (Hill *et al.* 2010; Regisford, 2012). The government, observers, and education practitioners want the STEM education curriculum to be able to internalize STEM values in student life to encourage increased student interest in a

career in the field of STEM after graduating from college. Especially as prospective MIPA teachers, it is hoped that they will have careers in the STEM field after graduation.

Several studies have examined STEM career interests at various levels of education ranging from elementary (Kim *et al.*, 2015; Campbell *et al.*, 2017; Peterson, 2018; Toma and Greca, 2018), intermediate (Aeschlimann, Herzog and Makarova, 2016; Kier *et al.*, 2014; Sadler, 2014; Robnett, and Leaper, 2013), and higher education levels (Beier *et al.*, 2019; Moakler and Kim, 2014). Knowledge about STEM career interests of teacher candidates can help researchers, teachers, government, and other education stakeholders to map their career tendency and create innovative learning strategies.

This study aimed to analyze the STEM career interest of prospective math and science teacher at Lampung University.

## 2. MATERIALS AND METHODS:

### 2.1. Research Sample

This study used a traditional survey method involving 300 students (269 female and 31 male) in which all participants agreed to spontaneously participate in this study once there is no official document demanded by the University to this kind of study. Participants were active students of Mathematics and Natural Sciences (physics, chemistry, biology) Education in the Department of Mathematics and Natural Sciences, Lampung University. The survey research design is a procedure in quantitative research in which the researcher surveys the sample to describe the attitudes, opinions, behavior, or characteristics of the population (Creswell, 2012).

### 2.2. Instrument

The instrument (survey) was adapted from the STEM Career Interest Survey (STEM-CIS) instrument developed by Kier *et al.* (2014). The instrument was adapted and transliterated into Indonesian, making it easier for research subjects to understand each item in the instrument. The instrument was then converted into a *google form* to make it easier for students to access, easy to

collect data, and paperless.

This 5-point Likert scale questionnaire consists of four dimensions or variables, namely career interests in the fields of science, mathematics, technology, and engineering, where each size includes eleven items. The full detail of the questionnaire is presented in Appendix 1.

### 2.3. Data Collection Technique and Analysis

The data collection technique is a conventional survey technique through the distribution of a questionnaire instrument to each sample. The students are asked to access the Google form website page, fill in questions in the form of a 5-Likert scale, and submit the results of their answers online.

Subsequently, the construct validity of the instrument used was determined for the data obtained using the exploratory factor analysis technique (EFA) using SPSS software version 23. Exploratory factor analysis (EFA) was carried out to uncover factor structures and correlation patterns between the observed variables (questionnaire items) and latent variables, which were considered as hidden variables representing these items.

Before further EFAs are carried out, it must first be tested against a group of data obtained, whether it is suitable for analysis by EFA. This can be done by observing the value of the Kaiser-Meyer-Olkin (KMO) sampling adequacy test and the Bartlett sphericity test. The Kaiser-Meyer-Olkin (KMO) test is a measure of how well the data fit for Factor Analysis. This test measures the adequacy of the sample for each variable in the model and the complete model. Statistics is a measure of the proportion of variance between variables that might be general variance. The lower the balance, the more your data fits in with Factor Analysis.

Meanwhile, the Bartlett sphericity test is used to compare the obtained correlation matrix (in this case, the Pearson correlation matrix) with the identity matrix. In other words, the Bartlett test checks whether there is redundancy between variables, which can be summarized by several factors. The Bartlett test is also able to identify unrelated variables and is therefore not suitable for structural detection. Small values (less than 0.05) of the significance level indicate that factor analysis might yield useful information with the data used.

The validation criteria in the EFA analysis are based on Stevens (2002), where items retained in the instrument must have a loading

factor more than 0.40, so items with a loading factor less than 0.40 will automatically be eliminated in the analysis of each item in the instrument. The principle of extraction of the main components with orthogonal rotation was used to estimate the number of possible factors while contributing to the construct validity in the developed instrument.

The reliability test for each dimension in the instrument is based on Cronbach's alpha coefficient calculation. Furthermore, determining the level of preference of STEM career interest (according to their perceptions) is conducted by determining the mean and standard deviation for each dimension and comparing them to the grand mean scores. The correlation of each dimension of STEM career interest is conducted by using the Pearson product-moment analysis.

### 3. RESULTS AND DISCUSSION:

The KMO and Bartlett chi-square test values obtained were 0.937 and 11872.889 ( $p < 0.05$ ), as shown in Table 1. These values indicate that the research data are suitable for use in the EFA analysis and are expected to provide useful interpretation.

After finding out that the research data obtained was ideal for EFA analysis, an investigation was carried out on the value of extraction communalities. Communalities shows the amount of variance in each variable that is considered. Initial communalities are estimates of variation in each variable recorded by all components or factors. For central component extraction, this is always equal to 1.0 for correlation analysis. Meanwhile, Extraction communalities are estimates of the variance in each variable that is taken into account by the component. Communalities have high enough extraction values ranging from 0.611 to 0.787, which shows that the components extracted represent the variables well (Table 2)

The researcher makes a limitation that items that can be accepted to represent latent factors are items that have a loading factor of more than 0.40, according to Stevens (2002) criteria. Stevens (2002) suggested that retained questions in the questionnaire must have a loading factor of more than 0.40. This has implications for the removal of items that have a loading factor of less than 0.40. The principle of extracting major components with orthogonal rotation was used in this study to estimate the number of possible factors while contributing to the construct validity in the scientific attitude instruments

developed. From the results of the EFA analysis, it was found that the items clustered into four main factors, with loading factors ranging from 0.575 to 0.848. Meanwhile, eight items were excluded from the EFA analysis due to factor loading values below 0.40. Furthermore, each factor can be declared reliable based on Cronbach's alpha complete information is 0.980, which indicates that the factors in the instrument have a high level of internal consistency to evaluate the attitude of prospective MIPA teachers for a career in the STEM field (Table 3).

### 3.1. Attitude level towards STEM careers

The STEM career attitude level analysis was conducted by comparing the mean values obtained for each latent factor against the grand mean, according to Suprpto (2016). A mean value more significant than the dignified way is seen as a dominant tendency for STEM careers in prospective MIPA teacher candidates. From the data in Table 4, information is obtained that science and mathematics have a mean value more significant than the grand mean. These results indicate that science and mathematics are the dominant tendencies of the attitude of prospective MIPA teacher students compared to technology and engineering.

### 3.2. Correlation between factors

Correlation analysis between factors was conducted by taking into account the Pearson product-moment correlation coefficient. From the results of the correlation analysis, information is obtained that all factors correlate significantly with a 99% confidence level (Table 5)

A factor analysis technique was used to identify structural factors of the attitude of the prospective MIPA teacher students to have a career in STEM. In general, the instruments have high validity and reliability for measuring the positions of prospective MIPA teacher students to pursue careers in the STEM field. The STEM career attitude instrument consists of 36 statement items in which these items can explain 62.437% of STEM career attitudes with a breakdown of 17.320%; 15.842%; 15.105%; and 14.171% for careers in science, mathematics, technology, and engineering. The results of this study also provided information that the attitude of the prospective MIPA teacher students for a career in the STEM field can be classified into four main factors, namely:

- a. Science career attitude (factor 1) consisting of 9 items ( $\alpha = 0.917$ ;  $s^2 = 7.320\%$ ); explore the

position of prospective MIPA teacher students to pursue careers in the field of science such as science assignments and study at school, interest in working in the sciences, and seriousness in science courses.

- b. Mathematics career attitude (factor 2) consisting of 9 items ( $\alpha = 0.927$ ;  $s^2 = 15.842\%$ ); explore the attitudes of prospective MIPA teacher students to pursue careers in the field of mathematics such as mathematics assignments and learning in school, interest in working in mathematics, and seriousness in mathematics courses.
- c. Technological career attitude (factor 3) consisting of 9 items ( $\alpha = 0.911$ ;  $s^2 = 15.105\%$ ); explore the perspectives of prospective MIPA teacher students to pursue careers in technology such as assignments and technology learning at school, interest in working in technology, and seriousness in technology courses.
- d. Engineering career attitude (factor 4) consisting of 9 items ( $\alpha = 0.936$ ;  $s^2 = 14.171\%$ ); explore the perspectives of prospective MIPA teacher students to pursue careers in engineering such as assignments and learning about engineering at school, interest in working in engineering, and seriousness in engineering courses.

Out of the four STEM career attitudes, the majority of MIPA teacher candidates prefer a career in the fields of mathematics and science over technology and engineering. This is indicated based on the mean value of the career of science and mathematics is higher than the value of the grand mean compared to technology and engineering. This certainly can be understood based on the specialization curriculum pursued by prospective MIPA teacher students, where most of the courses are dominated by science and mathematics. At the same time, classes that contain technological and engineering content will certainly not be too dominant. The results of the Pearson product-moment correlation analysis illustrate that each factor or dimension of STEM career attitudes correlates with each other significantly with a 99% confidence level. This result can be understood because STEM attitudes are indeed associated with each other, like the results of research from Suprpto (2016). Hence it does not rule out that STEM career attitudes will also influence each other.

The results of this study are consistent with previous studies that found that there is a positive impact of the STEM approach to the learning

process, which affects and increases the interest of students of vocational schools or undergraduate program students to continuing education and/or have a career in the field of STEM (Business Europe, 2011; Healy *et al.*, 2011). Besides, other studies have found that STEM education can have a direct impact on learning, both in schools and in universities. STEM education encourages the formation and strengthening of the character of students to be able to solve problems, be independent, thinkers, and, most importantly, be literate in technological literacy (Wells, 2019; Morrison, 2006). Thus, the results of this study are expected to have a positive impact on making changes to the curriculum in the department of mathematics and natural science education in fostering career spirit and motivation in STEM students.

#### 4. CONCLUSIONS:

Exploratory and reliability analysis revealed that the instrument used in this study had high internal consistency and was able to explain more than half of the overall STEM attitudes of MIPA teacher candidates. This indicates that the instrument is appropriate to be used for analyzing students' career interests in the STEM field and reasonably pleasant to explain the students' tendency to have a STEM career after graduating from college.

Moreover, the second aim of this study was to investigate which preference is more dominant among the four STEM fields. Mean, and grand mean comparison analysis revealed that science and mathematics career attitudes become the prevailing preference for the future career of prospective MIPA teachers. This indicates that working in the fields of science and mathematics is more desirable than technology and engineering;

The last, Pearson product-moment analysis confirmed that all factors significantly correlate with each other. It means that efforts to improve one dimension of STEM career attitudes will directly impact on improving career attitudes in different dimensions, and vice versa.

## **APPENDIX 1**

### **STEM Career Interest Survey (STEM-CIS)**

#### **Science (S)**

- S1 I am able to get a good grade in my science class.
- S2 I am able to complete my science homework.
- S3 I plan to use science in my future career.
- S4 I will work hard in my science classes.
- S5 If I do well in science classes, it will help me in my future career.
- S6 My parents would like it if I choose a science career.
- S7 I am interested in careers that use science.
- S8 I like my science class.
- S9 I have a role model in a science career.
- S10 I would feel comfortable talking to people who work in science careers.
- S11 I know of someone in my family who uses science in their career.

#### **Mathematics (M)**

- M1 I am able to get a good grade in my math class.
- M2 I am able to complete my math homework.
- M3 I plan to use mathematics in my future career.
- M4 I will work hard in my mathematics classes.
- M5 If I do well in mathematics classes, it will help me in my future career.
- M6 My parents would like it if I choose a mathematics career.
- M7 I am interested in careers that use mathematics.
- M8 I like my mathematics class.
- M9 I have a role model in a mathematics career.
- M10 I would feel comfortable talking to people who work in mathematics careers.
- M11 I know someone in my family who uses mathematics in their career.

#### **Technology (T)**

- T1 I am able to do well in activities that involve technology.
- T2 I am able to learn new technologies.
- T3 I plan to use technology in my future career.
- T4 I will learn about new technologies that will help me with school.
- T5 If I learn a lot about technology, I will be able to do lots of different types of careers.

- T6 My parents would like it if I choose a technology career.  
 T7 I like to use technology for class work.  
 T8 I am interested in careers that use technology.  
 T9 I have a role model who uses technology in their career.  
 T10 I would feel comfortable talking to people who work in technology careers.  
 T11 I know of someone in my family who uses technology in their career.

### Engineering (E)

- E1 I am able to do well in activities that involve engineering.  
 E2 I am able to complete activities that involve engineering.  
 E3 I plan to use engineering in my future career.  
 E4 I will work hard on activities at school that involve engineering.  
 E5 If I learn a lot about engineering, I will be able to do lots of different types of careers.  
 E6 My parents would like it if I choose an engineering career.  
 E7 I am interested in careers that involve engineering.  
 E8 I like activities that involve engineering.  
 E9 I have a role model in an engineering career.  
 E10 I would feel comfortable talking to people who are engineers.  
 E11 I know of someone in my family who is an engineer.

### **RESUMO**

O aumento da poluição nos recursos hídricos é proveniente praticamente de todas as atividades humanas, sejam elas domésticas, comerciais ou industriais. O meio ambiente não tem capacidade de absorver todos os poluentes, pois cada uma dessas atividades econômicas gera poluentes característicos que apresentam determinadas implicações ambientais e afetam diretamente na qualidade de qualquer recurso hídrico. O crescimento populacional é outro fator que leva ao aumento de geração de resíduos, dos quais se podem destacar os esgotos domésticos, ricos em nutrientes e, quando depositados irregularmente, causam desequilíbrio no corpo hídrico. O presente estudo tem como objetivo identificar a concentração do elemento fósforo na forma do íon fosfato nos recursos hídricos do litoral do Paraná. Para quantificar esse elemento, foi utilizado o método espectrofotométrico do azul de molibdênio. Avaliaram-se amostras de dez pontos de águas continentais da região litorânea que sofrem maior ou menor influência antrópica. Foram realizados ensaios no período de agosto de 2017 a maio 2019. Na metodologia analítica, foram utilizadas soluções de molibdato de amônio, ácido ascórbico, ácido nítrico e glicerina. Quando essas soluções são misturadas em amostras ou soluções padrão que contenham o elemento fósforo, há a formação do complexo azul de molibdênio. Foram realizadas cinco repetições em cada uma das amostras para que, no final, fosse obtido o valor médio das medidas. Observou-se que as concentrações de fósforo através do íon fosfato apresentaram resultados acima de 0,150 mg. L<sup>-1</sup>, valor máximo deste macronutriente em amostras de água preconizado pela legislação, exceto pelo resultado obtido no ponto 8 no mês de novembro, cuja concentração foi de 0,08 mg. L<sup>-1</sup>. Os resultados mostraram, portanto que há poluição nas águas continentais amostradas. Por consequência, é possível destacar que a alta concentração de íon fosfato nas amostras é oriunda da ação humana, principalmente naqueles rios que estão mais próximos a contingentes urbanos.

**Palavras-chave:** *Fósforo, Azul de Molibdênio, Macronutriente, Poluição da Água.*

### **ABSTRACT**

The increase in pollution in water resources comes from practically all human activities, whether domestic, commercial, or industrial. The environment cannot absorb all pollutants, as each of these economic activities generates specific pollutants, which have certain environmental implications and directly affect the quality of any water resource. Population growth is another factor that leads to an increase in the generation of waste, of which domestic sewage, rich in nutrients and, when deposited irregularly, causes an imbalance in the water body that can be highlighted. This study aimed to identify the concentration of the phosphorus element in the form of the phosphate ion in the water resources of the coast of Paraná. To quantify this element, the spectrophotometric method of molybdenum blue was used. Samples from ten points of continental waters in the coastal region were evaluated, which suffer a greater or lesser anthropic influence. Tests were carried out from August 2017 to May 2019. In the analytical methodology, solutions of ammonium molybdate, ascorbic acid, nitric acid, and glycerin were used. When these solutions are mixed in samples or standard solutions that contain the element phosphorus, there is the formation of the blue molybdenum complex. Five repetitions were performed in each of the samples so that, in the end, the average value of the measurements was obtained. It was observed that the phosphorus concentrations through the phosphate ion showed results above 0.150 mg L<sup>-1</sup>, the maximum value of this macronutrient in water samples, recommended by the legislation, except for the result obtained in point 8 in November, whose concentration was 0.08 mg L<sup>-1</sup>. The results showed, therefore, that there is pollution in the sampled continental waters. As a consequence, it is possible to highlight that the high concentration of phosphate ion in the samples comes from human action, especially in those rivers that are closer to urban contingents.

## 1. INTRODUÇÃO:

O aumento significativo da poluição nos recursos hídricos é proveniente praticamente de todas as atividades humanas, sejam elas domésticas, comerciais ou industriais (Costa e Rocha, 2017). O meio ambiente não tem capacidade de absorver todos os poluentes, pois cada uma dessas atividades econômicas gera poluentes característicos que apresentam determinadas implicações ambientais e afetam diretamente na qualidade de qualquer recurso hídrico (Pereira, 2004).

O crescimento populacional leva ao aumento de geração de resíduos, dos quais se podem destacar os esgotos domésticos, ricos em fósforo e nitrogênio e, quando depositados irregularmente, causam desequilíbrio no corpo hídrico (Cordeiro, Motyl, Rocha, 2019). O rio Itiberê é um dos rios do litoral paranaense com maior quantidade de despejo de esgoto *in natura* produzido na cidade de Paranaguá (Godoy, 2013).

No município de Paranaguá está localizado o maior porto graneleiro do hemisfério sul. O Porto de Paranaguá é o principal porto brasileiro em movimentação de grãos sólidos como soja, milho e fertilizantes (França, Moraes, Rocha, 2017). Desta forma, esse porto é um dos maiores corredores de importação e exportação desses produtos do agronegócio. Já a fase final do transporte desses produtos ocorre pela malha rodoviária e pela malha ferroviária local, regional e inter-regiões brasileiras. O transporte rodoviário é um dos principais responsáveis por inúmeros impactos ambientais no município de Paranaguá, provocando ações antrópicas que agredem o meio ambiente, afetam a economia e refletem na sociedade de forma negativa, mas também positiva (Mariano, 2013).

O Porto de Paranaguá conta com um sistema de logística reversa, ou seja, os caminhões e trens que chegam carregados com farelos ou grãos para a exportação retornam carregados com adubos ou fertilizantes para as regiões produtoras dos grãos (Silva, Souza, Rocha, 2018). Em ambos os casos, parte da produção se perde ao longo da linha de trem ou no acostamento da Rodovia BR-277, sendo consumida pelas aves ou roedores locais, ou sofrem decomposição natural. Decompostos ou não esses resíduos são transportados pelas águas das chuvas para os recursos hídricos da

região. Outro fator preponderante é a perda contínua de fertilizantes durante o processo arcaico de carga e descarga no Porto de Paranaguá. Quantidades significativas de fertilizantes caem na Baía de Paranaguá, sendo que os mesmos, após sua solubilização, são transportados para o interior do continente pelo processo de marés (Staszczak e Rocha, 2018).

A principal consequência dos impactos antrópicos nos ecossistemas aquáticos é a ocorrência acelerada de processos eutrofizantes (Smaha e Gobbi, 2003) que causam enriquecimento artificial desses ecossistemas pelo aumento das concentrações de nutrientes na água, principalmente compostos nitrogenados e fosfatados (Cassol *et al.*, 2012; Brasil, 2014). Este processo destaca-se pela interferência na qualidade da água para abastecimento da população local, morte de peixes e organismos de determinado ambiente, trazendo assim grande desafio de manejo e gerenciamento dos recursos hídricos (Pantano, *et al.*, 2016).

O uso de fertilizantes no Brasil é um dos fatores que mais se destaca devido ao país ser um dos maiores produtores mundiais de alimentos e agronegócio, sendo um dos maiores segmentos da economia brasileira que utiliza grandes concentrações dos mesmos, devido ao solo brasileiro ser pobre em fósforo (P), potássio (K) e Nitrogênio (N) (Molin *et al.*, 2009; Frazão *et al.*, 2014). Nota-se também que o agronegócio é responsável por 42% das receitas nacionais de exportações (Cunha e Rocha, 2015). Somente o porto de Paranaguá recebeu de janeiro a outubro 8,4 bilhões de toneladas de fertilizantes por via marítima (Silva e Fernandes, 2018).

Observando alguns trabalhos que avaliaram a contaminação antrópica da região litorânea Paranaense que corresponde às cidades de Antonina, Guaraqueçaba, Guaratuba, Matinhos, Morretes, Paranaguá e Pontal do Paraná (Cunha e Rocha, 2015), percebe-se que a concentração em solos (Reis, Cavallet, Rocha, 2014), em recursos hídricos (Reis *et al.*, 2015) e em sedimentos (Cazati, 2010) estão muito acima daqueles preconizados para esses recursos ambientais. Na Resolução nº 357/2005 do Conselho Nacional do Meio Ambiente (CONAMA) para ambientes lóticos, a concentração máxima do elemento fósforo é de 0,150 mg. L<sup>-1</sup>.

O fósforo tem função essencial para vários organismos vivos, como plantas e animais, além

de desempenhar um papel fundamental na produtividade primária dos organismos. Atualmente desempenha um papel importante nas atividades econômicas, principalmente na gestão da produção agrícola, usado como fertilizante (Pantano *et al.*, 2016). Não esquecendo que esses elementos estão entre os principais nutrientes que limitam a produtividade primária de grãos na agricultura, sendo assim a disponibilidade dos mesmos também influencia a variedade e abundância dos organismos aquáticos (Marguti, Ferreira Filho, Piveli, 2008). A emissão antrópica de nutrientes (N e P), para muitos ecossistemas aquáticos, vem superando de forma quantitativa as emissões naturais (Molisani *et al.*, 2013).

A metodologia considerada oficial para a determinação do elemento fósforo na forma fosfato é a espectrofotométrica com a formação do complexo azul de molibdênio (Kronka *et al.* 1997; Masini, 2008). Por meio dessa metodologia foi possível determinar a concentração desse elemento no litoral Paranaense, bem como monitorar os valores obtidos durante o estudo.

Portanto, o objetivo deste estudo foi avaliar e monitorar a concentração do elemento fósforo nos recursos hídricos da região litorânea Paranaense devido à importância estratégica econômica local dos diferentes rios avaliados (Silva; Souza; Rocha, 2018), bem como verificar se os mesmos estão de acordo com a resolução Nº 357/2005 estipulado pelo CONAMA.

## 2. MATERIAIS E MÉTODOS:

O macronutriente fósforo foi determinado espectrofotometricamente, na forma de fosfato, em amostras provenientes de rios, sendo que as amostragens foram realizadas trimestralmente pelo período de dois anos. Os ensaios nas amostras reais foram realizados após determinar a curva padrão das soluções padrões de fosfato no equipamento calibrado em comprimento de onda 660 nm.

### 2.1. Área de estudo e pontos de amostragem

Foram retiradas amostras de dez pontos geográficos das cidades litorâneas Paranaenses de Paranaguá e Pontal do Paraná (Tabela 1). Na Figura 1 é possível observar esses mesmos pontos, representados ao longo das Rodovias BR-277, PR-508 e PR-407, no mapa das cidades de Paranaguá e Pontal do Paraná. As coletas foram realizadas em agosto e novembro de 2017, fevereiro, maio, agosto, novembro de 2018,

fevereiro e maio de 2019. A prioridade foi a amostragem de pontos próximos ao Porto de Paranaguá e, posteriormente, foram avaliados recursos hídricos que sofrem forte influência das marés e todas as análises de cada etapa foram realizadas no mesmo dia da coleta.

Essas amostras foram transportadas para o Laboratório de Avaliação dos Impactos Ambientais (LAVIMA) da Região de Paranaguá da UNESPAR, *Campus* de Paranaguá, onde foram realizados ensaios para quantificar o elemento fósforo na forma do íon fosfato, segundo metodologia considerada padrão (Rice *et al.*, 2012).

### 2.1.1 Metodologia analítica

O elemento químico fósforo disponível foi determinado por espectrofotometria, na forma do íon fosfato, utilizando espectrofotômetro U2M Quimis. Após a mistura das amostras ou das soluções padrões com soluções reativas A (molibdato de amônio e ácido nítrico) e B (ácido ascórbico e glicerina), ocorreu à formação da coloração do azul de molibdênio (Masini, 2008). Em seguida realizaram-se todas as medidas dos valores de absorbância em 660nm, incluindo a calibração do equipamento e também obtenção do branco.

Todos os ensaios analíticos foram realizados com cinco repetições, para que dessa forma os possíveis erros, que comumente ocorrem em um processo analítico, fossem minimizados.

Utilizaram-se os valores médios de absorbância obtidos nos ensaios de cada uma das soluções padrão para traçar a equação padrão (Figura 2). Posteriormente, os cálculos foram realizados utilizando a equação padrão para obter os valores da concentração de  $P-PO_4^{3-}$  em cada um dos ensaios realizados nas dez amostras reais, bem como os resultados da média e desvio padrão das mesmas.

## 3. RESULTADOS E DISCUSSÃO:

Com os resultados obtidos em cada período amostral, produziu-se o gráfico dos valores de absorbância em função das concentrações de cada uma das soluções padrão de onde se obteve a equação padrão.

Na Figura 3 é possível observar o gráfico produzido com os resultados obtidos nos ensaios padrão do sexto período de amostragem. As equações lineares da reta produzidas em cada um

dos oitos períodos amostrais estão disponíveis na Tabela 2, sendo que com essas equações foi possível determinar a concentração de fósforo na forma de fosfato, em cada uma das amostras retiradas nos diferentes períodos e pontos amostrais.

Durante o monitoramento da concentração de fosfato, em todos os pontos amostrais da primeira fase (Figura 4), percebeu-se que a quase totalidade deles está muito acima do parâmetro máximo estabelecido pela Resolução Nº 357/2005 CONAMA. Verificou-se, nos mesmos, que as concentrações de fósforo apresentaram resultados acima de  $0,150 \text{ mg L}^{-1}$ , ou seja, quase 60 vezes superior ao parâmetro estipulado. O único valor abaixo da norma foi encontrado no Riacho localizado no Km 1 da Rodovia Matinhos, provavelmente devido ao processo de diluição que ocorre no período de chuvas, além desse local não sofrer processo significativo das marés.

Ao longo dessa segunda fase do projeto, percebeu-se que a concentração de fosfato, em todos os pontos amostrais e em todos os períodos amostrados estavam muito acima do parâmetro máximo estabelecido pela Resolução Nº 357/2005 CONAMA, que é de  $0,150 \text{ mg L}^{-1}$ . Verificou-se que esses valores são, no mínimo, seis vezes maiores que o valor estipulado pelo CONAMA e até quase sessenta vezes superior ao mesmo valor (Figura 5). Percebeu-se, ainda que a influência desses altos valores esteja relacionada com o processo de maré (Staszczak e Rocha, 2018), bem como pelo descarte inadequado de resíduos domésticos, comerciais e industriais da região litorânea (SILVA *et al.*, 2012). Todos esses fatores impactam de forma negativa na contaminação ambiental da região.

O fósforo em concentrações adequadas é importantíssimo em diferentes funções biológicas entre elas a fotossíntese, o metabolismo de açúcares, o armazenamento e a transferência de energia através do ATP, na divisão celular, no alargamento das células e na transferência da informação genética (Oliveira *et al.*, 2013).

Por outro lado, quando esse elemento se apresenta em excesso no ambiente, pode provocar diversos impactos negativos, com especial referência à qualidade das águas. Quando aumenta a concentração de nutrientes (fosfatos, principalmente) em rios e lagos, pode causar eutrofização, podendo ser visível em alguns pontos dos rios (Santos e Araújo, 2010). O aumento na concentração de fosfato chegou até nos pontos mais distantes do centro da cidade. Este fato, como já informado, está diretamente

relacionado tanto ao processo de influência das marés, como da proximidade dos mesmos com as rodovias responsáveis pelo excessivo fluxo de caminhões que transportam grãos e fertilizantes até o Porto (Souza *et al.*, 2019). Ao longo do percurso ocorre derramamento destes produtos, devido à baixa qualidade da rede de transporte, que vai acumulando-se na lateral da via, sendo levado pelo processo das chuvas para os rios próximos (Lopes *et al.*, 2019).

Avaliando pontualmente, foi observado que os pontos mais afetados pelo impacto antrópico foram os pontos amostrais 2, 3, 8 em agosto de 2019, e 8 e 9, em fevereiro de 2019.

É possível destacar que somente o ponto 9, em novembro de 2017, apresentou concentração abaixo do permitido pela resolução CONAMA.

Segundo Reis *et al.* (2015), as concentrações do elemento fósforo na sua forma mais estável, fosfato, já apresentavam valores acima do estipulado pelo CONAMA Nº 357/2005 nos rios Guaraguaçu e São Joãozinho, confirmando que estas águas continentais possuíam e continuam com altas concentrações do elemento fósforo. Mesmo o rio São Joãozinho, que é considerado um dos rios mais afastados e de difícil acesso.

Os valores de concentração de fósforo encontrados nos rios Itiberê, Rio da Vila, Rio Pery e Rio Guaraguaçu, são similares àqueles encontrados por Cunha *et al.* (2015), Souza *et al.* (2019) e também por Lopes *et al.* (2019). Esses locais sofrem fortes ações antrópicas, recebendo grande quantidade de esgoto sem tratamento. Aterro sanitário dos municípios de Pontal do Paraná e Matinhos que é localizado às margens do Rio Pery, sendo na verdade um “Lixão a Céu Aberto” como definido pelo Ministério Público do Paraná (2018). Além do gerenciamento arcaico do Porto de Paranaguá e a movimentação de fertilizantes pela malha ferroviária e rodoviária local.

#### 4. CONCLUSÕES:

Na maioria dos pontos amostrais, os valores das concentrações do elemento fósforo estiveram muito acima de  $0,150 \text{ mg L}^{-1}$ , parâmetro máximo da resolução Nº 357/2005 do CONAMA, principalmente quando se observam os valores encontrados no rio Itiberê, ponto mais próximo do Porto de Paranaguá. No entanto, o Riacho localizado no Km 1 da Rodovia Matinhos, provavelmente devido ao processo de diluição

que acontece no período de chuvas, além desse local não sofrer processo significativo das marés, foi o único local que apresentou valor abaixo daquele preconizado pela Resolução CONAMA, no mês de novembro/17.

Mediante os dados expostos, faz-se necessária a fomentação de trabalho nas diferentes áreas de conhecimentos, visando estabelecer diferentes meios para recuperação dos rios, evitando assim, o desequilíbrio no ecossistema.

Os valores elevados da concentração do íon fosfato estão relacionados com a ação humana, devido aos rios estarem próximos de regiões urbanas onde, na maioria das vezes, a rede de esgoto é depositada diretamente nos mesmos sem o devido tratamento.

Por fim, o fator preponderante da poluição elevada observada está relacionado com o gerenciamento arcaico do Porto de Paranaguá, onde os fertilizantes são retirados mecanicamente e não por sucção como nos portos mais modernos. Um sistema moderno por sucção evitaria a perda de fertilizantes que são solubilizados nas águas da Baía de Paranaguá e transportados, pelo efeito da maré, nos rios para regiões mais interiores do continente.

## RESUMO

Um dos principais contaminante da caulinita, o ferro, impacta diretamente na qualidade em seu valor comercial. O monitoramento espectroscópico, medido a profundidade da absorção da caulinita, é comparado com a literatura a fim de identificar possíveis contaminantes. A ocorrência da caulinita se deve à formação de minerais primários após a liberação parcial de cátions e silício. Este argilo-mineral tem uma forma simples, com imperfeições cristalográficas variáveis, especialmente na presença de ferro, que substituem o alumínio na cadeia mineral, causando várias desorganizações estruturais. A extração de minerais industriais combinada com estudos geológicos, permite o desenvolvimento de novas fontes de energia, como minerais argilosos, em particular caulinita. Dependendo da origem das caulinitas, a presença de óxidos de ferro em sua estrutura,  $\text{Fe}_2\text{O}_3$  e  $\text{FeO}(\text{OH})$  são comuns. Ao comparar os resultados da espectroscopia (fluorescência de raio-X, difração de raio-X; RAMAN) e no imageamento através do MEV-EDS, foi possível identificar a caulinita, com maior coeficiente de determinação, quando a proporção de caulinita atinge 60% ou mais na mistura. A caulinita pode ser identificada e quantificada com alta correlação na mistura a partir da absorção da amostra. Assim, o método possui grande potencial para auxiliar na quantificação e, conseqüentemente, na discriminação da qualidade da caulinita.

## ABSTRACT

One of the main contaminants of kaolinite, the iron, directly impacts quality in its commercial value. The spectroscopic monitoring, measured the depth of absorption of kaolinite, is compared with the literature in order to identify possible contaminants. The occurrence of kaolinite is due to the formation of primary minerals after the partial release of cations and silicon. This clay-mineral has a simple shape, with variable crystallographic imperfections, especially in the presence of iron, which replaces aluminum in the mineral chain, causing various structural disorganizations. The extraction of industrial minerals combined with geological studies, allows the development of new sources of energy, such as clay minerals, in particular kaolinite. Depending on the origin of the kaolinites, the presence of iron oxides in its structure,  $\text{Fe}_2\text{O}_3$  and  $\text{FeO}(\text{OH})$ , are common. By comparing the results of spectroscopy (X-ray fluorescence, X-ray diffraction, RAMAN) and imaging using SEM-EDS, it was possible to identify kaolinite, with a higher determination coefficient, when the proportion of kaolinite reaches 60% or more in the mix. Kaolinite can be identified and quantified with a high correlation in the mixture from the sample absorption. Thus, the method has great potential to assist in quantifying and, consequently, in discriminating the quality of kaolinite.

**Keywords:** Goethite; Clay Minerals; Spectroscopy.

## 1. INTRODUCTION

Brazil's extractive economy is mainly focused on supplying the metalworking industry (Schrecker *et al.*, 2018; Giacomini *et al.*, 2017; Paulino, 2014). About 85% by volume are of metallic minerals extracted in the country, and the other 15% are non-metallic (Macedo *et al.*, 2003; De Souza *et al.*, 2019). The extraction of industrial minerals combined with geological studies allows the development of new energy sources such as clay-minerals, in particular, kaolinite (Sruthi and Reddy, 2017). A large volume of reserves and production allows the development of the ceramic sector. Kaolinite prices are influenced by the availability of reserves, geographic location (transport), and aggregate technology for processing and treatment (Pardo *et al.*, 2018; Illera *et al.*, 2015). Clay minerals are hydrated aluminum silicates made up of layers of  $\text{SiO}_2$  tetrahedrons and  $\text{Al}_2\text{O}_3$  octahedrons, which are intercalated in proportions: 1: 1 (kaolinite) and 2: 1 (montmorillonite) (Klunk *et al.*, 2019a). These minerals are part of the group defined as hydrated silicates, essentially made up of aluminum, in addition to iron, magnesium, and other impurities (Klunk *et al.*, 2019b).

Clay minerals are widely used in the industry. The use of these minerals as raw material results from the quality of the material produced. Kaolinites can present different degrees of purity and crystallinity due to cationic exchanges, with contaminants such as quartz and iron oxides (Klunk *et al.*, 2019c). Thus, the identification of the minerals present in the clays, as well as their physical-chemical characterization, are critical points in determining and understanding the behavior of the materials for the quality control of the final product (Ruosso *et al.*, 2019; Klunk *et al.*, 2019d; Klunk *et al.*, 2020a). Depending on the origin of the kaolinites, structural defects can occur due to the presence of iron oxides in its structure, being hematite ( $\text{Fe}_2\text{O}_3$ ), and goethite ( $\text{FeO}(\text{OH})$ ) - predominantly, the most common (Klunk *et al.*, 2020b). These compounds can be predicted through geochemical modeling using speciation of the elements (Klunk *et al.*, 2015; Klunk *et al.*, 2019e,f,g).

Thus, it is necessary to evaluate the potential of these materials for applications in the traditional ceramic industry. The goethite concentration is directly related to the depositional system. The availability of water promotes the concentration of humic acids, favoring the

formation of  $\text{FeO}(\text{OH})$  (Klunk *et al.*, 2012). Usually, Fe oxides have a high specific surface, resulting in high anion adsorption power, contributing to the kaolinite ion exchange capacity. However, few studies relate the influence of goethite with kaolinite, mainly on the effect on mineralogy (Fraga *et al.*, 2014).

Therefore, the objectives of this study are to relate the contents of goethite in kaolinite under different mixtures and to follow the evolution of the system through the techniques of XRF, XRD, Scanning Electron Microscopy (SEM) images allied to Spectrometer Energy Dispersive X-ray (EDS and RAMAN). The basic structural unit of iron oxides is associated with the octahedral arrangement, in which each iron atom is surrounded by six oxygen and hydroxyls, so the oxides are differentiated by the type of octahedral arrangement. In this way, it is possible to identify the occurrence of goethite in kaolinite by the manifestation of functional groups related to iron.

## 2. MATERIALS AND METHODS

### 2.1. Sistema de Mistura

The mixtures were performed with kaolinite:goethite, powered (mean diameter < 62  $\mu\text{m}$ ), with a weight proportion of 90:10 % with increments of 10 % in goethite until the proportion of 10:90 %, respectively.

### 2.2. Characterization of the Materials

#### 2.2.1. X-Ray Fluorescence Spectroscopy

The chemical composition of the solid, liquid and gaseous materials can be easily determined by the X-Ray Fluorescence Spectroscopy (XRF), which allows the identification and quantification of chemical elements from almost the entire periodic table (Klunk *et al.*, 2015; Klunk *et al.*, 2018). When a sample is irradiated with primary X-Rays, the electron of the innermost layer of the atom is ejected, causing a void. The excited atom returns to the ground state through a series of electronic transitions. This electronic transition process emits characteristic fluorescent X-Rays. Such a phenomenon is known as X-Ray fluorescence (Elaiopoulos *et al.*, 2010).

Therefore, each element emits characteristic radiation (energy and wavelength defined) that are detected and used for qualitative analysis. The quantitative information of the elements present in the sample is directly related to the intensity of the radiation emitted (Elaiopoulos *et al.*, 2010).

The X-Ray fluorescence technique can be divided into dispersive wavelength (sequential or simultaneous), dispersive, and special energy categories (synchrotron radiation source, total reflection, and particle induction). The dispersive energy fluorescence (EDXRF) technique has a lower resolution than the wavelength dispersion technique (WDXRF), but it is also widely used for rapid and exploratory analysis (Somerset, 2004).

X-Ray Fluorescence by wavelength dispersion (WDXRF) using the fundamental parameters (FP) method provides semi-quantitative and multi-elemental analyzes, as well as being non-destructive and fast. This method relates the theoretical fluorescence intensity of the chemical elements by means of samples of known chemical composition and the measured fluorescent intensity, thus, being able to determine the unknown chemical composition (Caetano *et al.*, 2015a). The XRF technique is not very sensitive for the detection of light elements due to induced Auger emission that reduces the intensity of XRF in the sample (Caetano *et al.*, 2015b).

### 2.2.2. X-Ray Diffraction

The X-Ray Diffraction (XRD) technique has wide application in the field of material characterization due to the information it provides on the mineralogical composition, the arrangement of the atoms and the study of details of the lattice structures in crystalline of the various materials (Caetano *et al.*, 2015c; Cataluña *et al.*, 2018). To identification of the compounds present in kaolinite and Goethite, DRX is an indispensable tool because this type of material has several compounds in crystalline form. X-rays are generated both by the deceleration of the electrons in a metal target and by the excitation of the electrons of the target atoms. An electron bombarded copper target is considered a good target for producing a strong line to CuK $\alpha$  (Caetano *et al.*, 2018; Cataluña *et al.*, 2017).

The phenomenon of diffraction occurs because X-Rays are scattered around the ordered environment of a crystal, causing interference between X-Ray waves. Constructive and

destructive interferences form patterns capable of providing information regarding the characteristics of the compounds present in a sample. Diffraction occurs when the wavelength of radiation is comparable to the characteristic spacings within the object that causes diffraction. Therefore, in order to obtain diffraction patterns of layers of atoms, it is necessary to use radiation having a wavelength comparable to the spacing of the layers, which is the case with X-Rays (Zhang *et al.*, 2018; Suzzoni *et al.*, 2018). The main diffraction methods are: i) Laue Method, which is used for the determination of crystal orientation in solid-state physics experiments; ii) Method of rotating crystal used for the determination of the configuration of enzymes, determination of the form of molecules, among other applications; and iii) Powder Method for Sprayed Samples (Pietzsch *et al.*, 2015; De Aza *et al.*, 2014).

In the diffraction technique by the powder method, a monochromatic X-Ray beam is directed to a sprayed sample, spread on a support, and the diffraction intensity is measured when a detector is moved at different angles. The pattern obtained is characteristic of the material in the sample and can be identified by comparison with standards base of data from ICDD (Joint Committee on Powder Diffraction Standards - JCPDS) da International Union of Crystallography (Cora *et al.*, 2014; Yan *et al.*, 2017).

Thus, XRD by the powder method provides a fingerprint of the sample. It can also be used to identify the size and type of the unit cell by measuring the spacing of the lines in the diffraction pattern (Miranda-Trevino and Coles, 2003).

The central equation for analyzing the results in a powder diffraction experiment is the Bragg equation ( $2d \sin \theta = \lambda$ ); were,  $\theta$  are the angles at which constructive interference occurs with the spacing  $d$  of the layers of atoms in the samples for X-rays of wavelength  $\lambda$  (Atkins e Jones, 2001). X-rays are reflected by the crystal only if the angle of incidence satisfies the condition established by Bragg's Law (Castrillo *et al.*, 2015; Zulfiqar *et al.*, 2015).

### 2.2.3. Scanning Electron Microscopy and Spectrometer Energy Dispersive X-ray

The morphology of materials can be studied by obtaining images through the Scanning Electron Microscopy (SEM) and Spectrometer Energy Dispersive X-ray (EDS) analysis, which provides micrographs at higher resolutions than

those provided by light microscopy, which is limited by diffraction effects of the order of magnitude of the wavelength of the light (Klunk *et al.*, 2019e; Rong *et al.*, 2008; Shahwan *et al.*, 2005; Frost *et al.*, 2002; Gupta *et al.*, 2011).

In a scanning electron microscope, the surface of a solid sample is swept with an electron beam. Samples that conduct electricity are easier to study because the free electron flow minimizes the charge accumulation and the possibility of thermal degradation of the sample. A number of techniques were developed to obtain electron microscopy images of non-conducting samples. The most common procedure involves coating the surface with a thin metallic film.

#### 2.2.4. Raman Spectroscopy

Raman spectroscopy is a spectroscopic technique used to observe vibrational, rotational, and other low-frequency modes in a system (Frost *et al.*, 1997; Klopogge, 2017). This technique is commonly used in chemistry to provide a structural fingerprint by which molecules can be identified (Khanna, 1981; Thibau *et al.*, 1978; De Faria *et al.*, 2007; Clark and Curri, 1998; Oh *et al.*, 1998).

### 3. RESULTS AND DISCUSSION

#### 3.1. Chemical Composition

The chemical composition of Kaolinite and Goethite with its respective mixtures was determined by XRF found in Figure 1. The present compounds are derived from the inorganic fraction in both Kaolinite and Goethite, and therefore, the results are presented in the form of oxides. According to Figure 1, there were large variations between the contents of the main components (kaolinite 100% and goethite 100%) of the different mixtures.

The content of the principal compounds forming the kaolinite structure are  $\text{SiO}_2$  and  $\text{Al}_2\text{O}_3$ , and for goethite is  $\text{Fe}_2\text{O}_3$  (in the form of oxide as read from the XRF equipment). For the kaolinite, the  $\text{SiO}_2$  content varied from 52.80% (100% Kaolinite) to 6.58% (represented by the mixture of G90% + K10%) and the  $\text{Al}_2\text{O}_3$  content ranged from 38.90% (100% Kaolinite) to 3.71 % (represented by the mixture of G90% + K10%).

Thus, for the compounds forming the

goethite structure, the amount of  $\text{Fe}_2\text{O}_3$  varied from 5.97% in the mixture of G 10% + K 90% to 84.42 in the mixture of G 90% + K 10%. Figure 1 shows all fractions of a mixture of kaolinite and goethite.

#### 3.2. Mineralogical Composition

The technique of XRD allowed the identification of the crystalline phase's present kaolinite and goethite. Figure 2 shows the diffractograms of the samples of Kaolinite and Goethite (pattern and in the study), respectively.

The XRD pattern of the kaolinite sample is shown in Figure 2a. The spectrum of the kaolinite sample contains all the major peaks referring to (Joint Committee on Powder Diffraction Standards) JCPDS, database file (PDF-01-089-6538), thus indicating the formation of  $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$ . The main (hkl) indices of kaolinite like (001) and (002) are indicated in the pattern. The peaks are slightly broad, indicating a smaller crystal size (Phoebe and Medard 1991; Jehan *et al.*, 1970).

The XRD pattern of the goethite samples is shown in Figure 2b. The spectrum of the goethite sample contains all the major peaks referring to (Joint Committee on Powder Diffraction Standards) JCPDS, database file (PDF-17-0536), thus indicating the formation of  $\alpha\text{-FeOOH}$ . The main (hkl) indices of goethite like (020), (110), (120), (130), (111), (121), (140) and (221) are indicated in the pattern. The peaks are slightly broad, indicating a smaller crystal size (Ghosh *et al.*, 2012).

The results of the XRD analysis indicate that in the samples of kaolinite (A) pattern and in the study, we showed the absence of goethite. Therefore, in the samples of goethite (B) pattern and in the study, we find the same behavior of absence of compounds of another nature, thus without traces of kaolinite.

The difference in relative intensity of the diffraction peaks found in the kaolinite and goethite pattern when compared to Kaolinite and Goethite in the study may indicate different proportions of the phases found, as may be the result of sample preparation in the X-ray diffraction tests. The discrepancies between the amounts of the compounds found in the different samples can be attributed to the different geological conditions in the formation of kaolinite and goethite in the study.

### 3.3. Morphology

The technique of Scanning Electron Microscopy (SEM) images allied to Spectrometer Energy Dispersive X-ray (EDS) analysis were used in this present work for the study of morphology. The objective is to complement the other characterization techniques in the evaluation of the shape of the particles and composition present in the samples. Figure 3 shows us the micrographics' of Kaolinite and Goethite in the study.

In Fig. 4 are the micrographies of the mixture of 50% kaolinite + 50% Goethite (A) with their respective EDS (B and C). At point 051 and 052 (Fig. 4A) the Spectrometer Energy Dispersive X-ray show particularity in the diffractogram. Characteristic of each mineral phase in the blend. Kaolinite is represented in EDS-051 and Goethite in EDS-052.

### 3.4. Raman Spectroscopy

The Raman spectroscopic analysis identified the phase of goethite (fig. 5). Raman bands occurring at 299, 400, 484, 550, and 674  $\text{cm}^{-1}$  were assigned to the Fe-OH symmetric bend; Fe-O-Fe/-OH symmetric stretching; Fe-OH asymmetric stretching and Fe-O symmetric stretching, respectively (Dunnwald and Otto 1989; Kieser et al., 1983; Boucherit et al., 1991). As the amount of kaolinite increases in the mixture, the RAMAN spectrum reveals a decrease in Goethite band.

## 4. CONCLUSIONS

With the results obtained from techniques used allowed the following conclusions to be drawn:

- XRD identified crystalline phases of Kaolinite and Goethite;
- XRF showed the compounds present and derived from the mixture fraction in both Kaolinite and Goethite;
- SEM-EDS showed the grain morphology in the Kaolinite mixture 50% + Goethite 50% with the respective compositions);
- RAMAN (reveals a decrease of Goethite peaks as the percentage of Kaolinite increases in the

mixture) made it possible to characterize Kaolinite and Goethite in a mixing system.

We show in this research the potential of spectroscopy in the identification and quantification of mineral kaolinite in mixtures with mineral Fe. We conclude that kaolinite can be identified and quantified with a high correlation in the mix from the depth of the main diagnostic absorption feature with little sample preparation. Thus, the method has great potential to assist in quantification and, consequently, in the discrimination of kaolinite quality.

With little or no sample preparation, the spectroscopy can be used in obtaining many important information of mineralogy. The spectroscopy is a non-expensive, fast, and non-evasive, or little evasive methodology that offers great potential for the identification and qualification of minerals and mix.

## RESUMO

Este estudo foi realizado para estimar o nível de alguns metais pesados, principalmente chumbo (Pb), cádmio (Cd), cromo (Cr) e cobalto (Co) no solo e nas folhas de trigo de algumas lavouras de trigo na província de Basra e Maysan; as áreas de amostragem foram Al-Qurna, Al-Madinah, Al-Amara, Kumit, Ali Al-Sharqi e Ali Al-Gharbi. A análise foi realizada utilizando um espectrofotômetro atômico de chama. Os resultados indicaram um aumento nas concentrações dos metais pesados mencionados acima em todas as áreas examinadas; Verificou-se que os níveis em solos agrícolas excediam os limites internacionalmente permitidos, de acordo com as normas da UE-2000; os níveis mais altos de poluição foram observados no local de Al-Qurna, com diferenças significativas em relação a outros locais, para as concentrações disponíveis e totais de metais pesados no solo. Indicando a disponibilidade dos metais, de acordo com as concentrações disponíveis no solo analisado, foi o seguinte: chumbo (21,32) > cobalto (14,63) > cromo (11,06) > cádmio (1,15) em mg/kg de solo. Além disso, os resultados mostraram que o maior teor de chumbo nas folhas de trigo foi examinado nos campos de Qurna (0,175 mg/kg), seguido por Amara com uma concentração de 0,136 mg/kg. A menor concentração de chumbo foi observada nas folhas de trigo nos campos de Kumit (0,007 mg/kg). Em relação à concentração de Cd nas folhas de trigo, o nível mais alto foi observado em Al-Qurna, com diferença significativa em relação aos demais campos, atingindo 0,009 mg/kg. A menor concentração Cd registrada em Ali Al-Gharbi, que atingiu 0,002 mg/kg. Os resultados da correlação entre a concentração disponível de elementos de metais pesados e as características do solo revelaram uma correlação significativa entre o pH do solo e as concentrações disponíveis de chumbo, cádmio e cromo, enquanto não foi observada correlação com o cobalto e uma correlação significativa entre a CE do solo e o chumbo, e uma correlação negativa altamente significativa com o cobalto. Os resultados provaram os altos níveis de poluição em todas as áreas examinadas nas províncias de Basra e Maysan.

**Palavras-chave:** Metais pesados, poluição, Iraque, textura do solo, planta de trigo.

## ABSTRACT

This study was conducted to estimate the level of some heavy metals, mainly Lead (Pb), cadmium (Cd), chromium (Cr) and cobalt (Co) in the soil and wheat leaves of some wheat fields in Basra and Maysan province; the sampling areas were Al-Qurna, Al-Madinah, Al-Amara, Kumit, Ali Al-Sharqi, and Ali Al-Gharbi. It was performed the analysis using the Flame Atomic Spectrophotometer. The results indicated an increase in the concentrations of above mentioned these heavy metals in all examined areas; the levels in agricultural soils were found to be exceeding the internationally permissible limits according to EU-2000 standards, the highest levels of pollution were observed at Al- Qurna site with significant differences than other sites for both available and total HMs concentrations in soils. Indicating that the arrangement of the metals according to their available concentrations in the analyzed soil was as follows: lead (21.32) > cobalt (14.63) > chromium (11.06) > cadmium (1.15) as mg/Kg of soil. Additionally, results showed that the highest lead content in the wheat leaves was examined in the Qurna fields (0.175 mg/kg), followed by Amara with a concentration of 0.136 mg/kg. The lowest concentration of lead was observed in wheat leaves in the Kumit fields (0.007 mg/kg). In terms of Cd concentration in wheat leaves, the highest level was observed in Al-Qurna, with a significant difference from other fields, reaching 0.009 mg/kg. The lowest concentration of this HM was recorded in Ali Al-Gharbi, which

reached 0.002 mg/kg. The results of the correlation between the available concentration of heavy metals elements and soil characteristics revealed a significant correlation between the soil pH and lead, cadmium, and chromium available concentrations, whereas no correlation with cobalt and a significant correlation between soil EC and lead was observed and a highly significant negative correlation with the cobalt. Results proved the high levels of pollution in all examined areas in Basra and Maysan provinces.

**Keywords:** Heavy metals, pollution, Iraq, soil texture, wheat plant.

## الملخص

أجريت هذه الدراسة لتقدير مستوى بعض المعادن الثقيلة وهي الرصاص، الكاديوم، الكروم والكوبلت في تربة وأوراق بعض حقول الحنطة في محافظتي البصرة و ميسان. وكانت مناطق أخذ العينات هي القرنة والمدينة والعمارة وكميت وعلي الشرقي وعلي الغربي. تم إجراء التحليل باستخدام جهاز مطياف الامتصاص الذري. أظهرت النتائج زيادة في تراكيز هذه المعادن الثقيلة في جميع المناطق التي تم فحصها. تبين أن مستويات التربة الزراعية تجاوزت الحدود المسموح بها دولياً وفقاً لمعايير الاتحاد الأوروبي لعام 2000 ، وقد لوحظت أعلى مستويات التلوث في موقع القرنة مع وجود فروقات معنوية عن المواقع الأخرى لكل من تراكيز المعادن الثقيلة الكلية في التربة والتراكيز الجاهزة وكذلك محتوى أوراق الحنطة من المعادن الثقيلة. أوضحت النتائج أن ترتيب المعادن حسب التراكيز الجاهزة في التربة هو كالتالي: الرصاص (21.32) < كوبالت (14.63) < كروم (11.06) < كاديوم (1.15). بالإضافة إلى ذلك ، أظهرت النتائج أنه تم فحص أعلى محتوى من الرصاص في أوراق القمح في حقول القرنة (0.175 ملغم / كغم) تليها العمارة بتركيز (0.136 ملغم / كغم). ولوحظ أقل تركيز للرصاص في أوراق الحنطة في حقول كميت (0.007 ملغم / كغم). أما تركيز Cd في أوراق الحنطة فقد لوحظ أعلى مستوى في القرنة مع وجود فرق معنوي عن الحقول الأخرى حيث بلغ 0.009 ملغم / كغم. وسجل أقل تركيز لهذا المركب في علي الغربي والذي بلغ (0.002 ملغم / كغم). أظهرت نتائج الارتباط بين التركيز الجاهز للعناصر الثقيلة وخصائص التربة وجود علاقة معنوية بين الرقم الهيدروجيني للتربة والرصاص والكاديوم والكروم الجاهز في حين لم يلاحظ أي ارتباط بالكوبلت ، ووجد ارتباط بين ملوحة التربة والرصاص وارتباط سالب مع الكوبلت. أثبتت النتائج ارتفاع مستويات التلوث في جميع المناطق التي تم فحصها في محافظتي البصرة وميسان.

**الكلمات المفتاحية:** المعادن الثقيلة، التلوث، العراق، نسجة التربة، نبات الحنطة.

## 1. INTRODUCTION

Wheat is one of the main staple foods for feeding human populations throughout the world. Wheat crop *Triticum aestivum* L. is considered as one of the most important and economic crops in the world; and has a substantial role in food reserve all over the world, including Iraq. Their nutritious significance as a source of carbohydrates is remarkably increased during the last decades, and about 4.5 billion people of the third world are consuming wheat on a daily bases (Pathak and Shrivastova 2015; Verma and Khah, 2016). Nowadays, this crop is cultivated in more than seventy different countries worldwide, with approximately 920,096 acres of cultivated areas with around 3,052,939 million tons of harvested grains (FAO, 2017). Iraq, among these countries with wheat production 2974 thousand tons, as well as an area of 4,215,906 acres (Central Agency for Statistics and Information Technology, 2017).

Wheat plant is hugely influenced by several biotic and abiotic factors, causing a significant reduction in their production; among these abiotic factors; environmental pollution is raised as one of the most problematic stressors, and the direct impact of environmental pollution on human health has generated an increase of global concern. Heavy metals are among the most dangerous pollutants, and the seriousness of these pollutants is due to their toxicity and

tends to accumulate in the soil and tissues of living organisms as well as their degradable behavior (Dalman *et al.*, 2006; Akbarzade, 2015; Baghvand *et al.*, 2010). Heavy metals are defined as metals or semi-metals whose density is more than (5 g/cm<sup>3</sup>) (Sussiu *et al.*, 2008). Heavy metals occur naturally, but they also enter into the ecosystem throughout at different concentrations of the anthropogenic activity (You *et al.*, 2015). Heavy metals, among them, are necessary for living organisms but at low concentrations and are toxic at high concentrations such as iron, zinc, chromium, and copper, while lead, cadmium, and mercury are considered as unnecessary elements that have no vital role yet and are toxic at any concentration (McGrath *et al.*, 2001)

Soil is the main storehouse of heavy metals that are emitted to the environment, and that soil pollution, especially agricultural ones, has raised the interest of specialists in this field, not only because of the accumulation of these minerals in the soil but because of the transfer of these toxic metals to crops that grow in polluted soils leading to their entry into the food leading to a significant effect on human health; in addition to plant growth and development (Huand *et al.*, 2007). Soil heavy metals are transported and accumulated in plant tissues that are consumed by humans, leading a severe accumulation in fatty tissue and cause nerve damage and influence on the endocrine system, immunity, and

natural cellular metabolism and other processes (Waisberg *et al.*, 2003; Wang, 2013).

Plants are one of the most sensitive types of organisms that capable of concentrating high levels of heavy metals because they are immobile and their ability to accumulate minerals by absorbing them from the soil or through precipitation into the atmosphere (Zurayk *et al.*, 2001). Plant responses to heavy metals are varied according to the plant species, heavy metals, and their concentrations or forms, the responses appear on plants through their morphology to the biochemical level, such as increasing or decreasing the level of some compounds and molecules in cells or in physiological and biological processes and anatomical composition of the plant, and their effect may reach the level of genetic stability (Shahid *et al.*, 2014). The heavy metals toxicity to plants may be attributed to the enzyme inhibition by binding their sulfhydryl groups (Choudhry and Panda, 2004), it reduces the relative content of water and transpiration by affecting the water balance (Krantev *et al.*, 2006), and increasing the permeability of the plasma membrane. Inhibition of photosynthesis pigments such as chlorophyll-a, b, and carotenoids, and increases reactive oxygen species (ROS) are other plant responses to heavy metals accumulation (Abass *et al.*, 2016); lipid peroxidation is one of the most common responses to heavy metals accumulation on plant cell level (Zouri *et al.*, 2016).

Among the toxic heavy metals, the most dangerous ones are lead, cadmium, chromium, and cobalt, many local studies have indicated the high levels of pollution of heavy metals in Iraqi soil and their transcendence to the internationally accepted limits (Abass *et al.*, 2015; Al-Jabary *et al.*, 2016). The internationally permitted rate according to the standard indicators of lead in agricultural soils is 100 mg/kg of soil and cadmium 3 mg/kg soil. It was found that the rate of accumulation of lead in the different soils of Basra exceeded the international limits, some of which reached 270 mg/kg, and cadmium at a rate of 9 mg/kg of soil (Abass *et al.*, 2015; Abass *et al.*, 2017), indicated that there is a variation in the accumulation rate of lead, cadmium, chromium and nickel elements in different regions of Maysan Governorate, some of which are across the internationally permissible level (Tawfiq and Ghazi, 2017). The aims of the present work were to determine the heavy metals pollution in different wheat fields soil and plant parts in Basra and Maysan governorates.

## 2. MATERIALS AND METHODS

The study was conducted at the laboratory of the Plant Protection Department/ from the College of Agriculture of the Basra University of Basrah.

### 2.1 Description of sampling sites

Maysan province is located in the southeastern part of Iraq, and it is confined between two latitudes (15-31° - 45-32) in the north and between longitude (30 - 46° - 30 - 47°) in the east, and it is bordered in the south by Basra province, while it is bordered in the east and northeast by Iran.

Basrah Governorate is located in southern Iraq and is bordered by Iran, Kuwait, and Saudi Arabia. It is located at 30.53 degrees north latitude, 47.79 degrees east longitude, and 3 meters above sea level. Maysan Governorate is located along with the Basrah Governorate to the north. Six different regions in Basra and Maysan were selected to collect soil samples and leaves of wheat plants. The study sites were: Al-Qurna and Al-Madinah in Basrah province, Al-Amara, Ali Gharbi, Ali Al-Sharqi, and Kumait in Maysan province.

### 2.2 Samples collection

Five fields were selected from each site, marked in Figure 1, and compound soil samples were taken at a depth of 30 cm from each site. Samples of wheat were collected at the age of two months and brought to the laboratory.

### 2.3 Samples preparation

The soil samples were air-dried, mixed, and homogenized well, then passed through a plastic sieve with a diameter of 2 mm, after that the following characteristics were estimated:

#### 2.3.1 Soil texture

The Pipette method was used in Miller and Miller (1987), after extracting the proportions of the three soil segments of sand, silt, and clay - the soil texture triangle is used to determine the soil texture.

#### 2.3.2 Organic matter

It was weighed 1 gram of soil in a glass beaker of 500 ml capacity and add 10 ml of potassium dichromate solution N1, add

concentrated sulfuric acid, move the beaker well to mix the suspension, leave for 30 minutes, add 200 ml of distilled water, add 10 ml of concentrated phosphorous acid. Leave the mixture to cool, add 10 drops of Di-phenyl amine guide, add a magnetic bar and put the beaker on a magnetic stirring device, titrate the ferrous sulfate solution and ammonium sulfate 0.5 M until the color changes from blue to purple to green, bring two blanks containing all the solutions except the soil. The proportion of organic matter is calculated according to the formulas mentioned in (Schulte, 1995).

### **2.3.3 Cation exchange capacity (CEC)**

Weigh 4 g anaerobically dry soil in a 40 mL centrifuge tube, add 1 mL of sodium acetate solution (ternate water molecules) N1, shake the tube for five minutes, remove the plug from the tube and place the tube in the centrifuge 3,000 r / min until it becomes floating liquid is clear, the clear liquid is completely filtered and then cast. Repeat the process four times with 33 mL of sodium acetate solution (triple water molecules) N1. Each time the floating liquid is filtered, then add 33 mL of 95% ethyl alcohol, clog the tube and shake for 5 minutes, lift the plug and place the tube in the centrifuge until The floating liquid becomes clear. Wash the sample with ethyl alcohol (95%) three times, each time the floating liquid is filtered so that the clear conductivity of the clear liquid after the third wash is less than 400  $\mu\text{S}/\text{cm}$ . Replace the chopped sodium from the sample by adding 33 mL of ammonium acetate solution N1 three times each time shaking for 5 minutes. We measure the soil extract and spectrum readings by flame spectroscopy at a wavelength of 767 nm. Calculate the sodium (Na) concentration according to the calibration curve. (Polemio and Rhoades, 1977).

### **2.3.4 Soil Ph**

From dry soils it weighed 50 g in a 100 mL glass Baker, then add 50 mL of distilled water, then mix the suspension and leave it for 3 minutes and move the suspension every 10 minutes, after an hour we move the suspension and then place the combined electrode (German model PH 7110) in the suspension with a depth of about 3 cm. The reading was taken after 30 seconds (McLean 1982).

### **2.3.5 Soil salinity**

Prepare a suspension (1: 1) (soil: water), then filter the suspension using a vacuum

filtration system, put filter paper type Whatman No.42 and in a Buchner funnel, then transfer the filtrate to a 5 mL beaker, then record electrical conductivity using (Italian-made Milwaukee-SM302) (Richards, 1954).

### **2.3.6 Percentage of major nutrients N.P.K**

Ion ( $\text{NH}_4$ ) was estimated by extracting with potassium chloride solution (2N) and using  $\text{MgO}$ , and measuring it using the microceldal device. The nitrate ion was estimated by reducing it via the Devarda alloy, then by using the microceldal device according to a method according to the Brenner (1965) method described in Black (1965). Phosphorous was extracted using  $\text{NaHCO}_3$ , then with ammonium molybdate and ascorbic acid. It was estimated by the spectrophotometer at a wavelength of 882 nm Page *et al.* (1982). Potassium was extracted with ammonium acetate solution (1N) and then measured with Flame- photometer (Black, 1965).

### **2.4 Determination of heavy metals in soil samples and wheat leaves**

Determination of the total and available concentrations of lead metal (Pb), cadmium (Cd), chromium (Cr) and cobalt (Co) in the soil was performed using the Flame Atomic Spectrophotometer (Perkin Elmer AAS analysis 300, USA) according to the following extraction methods:

#### **2.4.1 Extraction of the total concentrations of heavy metals in the soil**

Extraction was done according to the method described in Davidson (2013) by acid digestion procedure, 1 g of dried soil was crushed in a Teflon Beaker heat-resistant plastic baker and moisten with water, then 10 mL of  $\text{HNO}_3$  was added, the mixture was then heated at  $75^\circ\text{C}$ , and left to evaporate until the volume remains 2 mL, then add a mixture of  $\text{HNO}_3$  (25 mL) and 5 mL  $\text{HClO}_4$  (70%) and 1 mL of Hydrofluoric acid (HF) gradually and carefully and heated the mixture (without boiling) until the appearance of brown fume, then add 1 mL of hydrofluoric acid (1:1) (volume:volume), Half an hour after the appearance of brown fume, then heated for a period of 10 minutes, then diluted with distilled water to 100 mL.

#### **2.4.2 Extraction of the available concentrations of heavy metals in the soil**

Extraction solution consisting of: (0.005 mol/L of DTPA, diethylenetriaminepentaacetic acid, 0.01 mol/L of calcium chloride  $\text{CaCl}_2$  and 0.1 mol/L of TEA Triethanolamine), was used to extract the available concentrations of heavy metals in soils; 30 ml of the extraction solution was added to 15 g of dry soil in a glass jar, then shaken well for two hours with a mechanical shaker, then filtered through Whatman No. 4 filter paper, and diluted to 100 ml with distilled water.

#### **2.4.3 Extraction of heavy metals in the wheat leaves**

Heavy minerals were extracted from the wheat plant leaves using the method of wet acid digesting according to the protocol described in Jones (1984). Briefly, by adding 5 ml of nitric acid (70%) and 1.5 ml of hydrochloric acid (60%) to 0.5 g of a sampled leaves, then heated until brown fume disappeared, 5 ml of dilute hydrochloric acid (1:1) was added, and the mixture was diluted to 25 ml with distilled water.

#### **2.5 Permissible limits for heavy metals**

The permissible standard limits for the total soil concentration of heavy metals were adopted from the European Union (2006) to compare the results, and the permissible levels are Lead (Pb) 100 mg/kg, Cadmium (Cd) 3 mg/kg, Chromium (Cr) 100 mg/kg and Cobalt (Co) 50 mg/kg.

#### **2.6 Statistical analysis**

The experiment was designed using Complete Randomization Design (C.R.D), and the Least Significant Difference (L.S.D) test was used to compare the averages at the 0.05 probability level. The Statistical Package for Social Science (SPSS) version (21) was applied data analysis, and the results represented an average of three replicates per treatment.

### **3. RESULTS AND DISCUSSION:**

#### **3.1 Soil properties:**

The results of Table (1) showed the soil properties for the study sites that were chosen to assess the levels of pollution of heavy metals in some fields of Basra and Maysan provinces. The results showed that the pH values were close between the study sites, and their values ranged

between 7.2 and 8.1. Al-Qurnah fields recorded the highest electrical conductivity value of 16.76 dS/m and the lowest value in Ali Al-Gharbi fields, which was 7.50 ds /m. The results of the organic matter percentage for the study sites showed that the Al-Qurna site recorded the highest percentage by 1.80% and with a significant difference from other examined sites. As for the Cation exchange capacity ions, Al-Madinah recorded the highest value, which was 34.71 Ctmol/kg, and the lowest value was in a Kumit site of 13.49 cm/kg, and the results showed that the highest value of nitrogen content element was seen in Ali Al- Sharqi fields by 113.17%, and there are no statistically significant differences between the values of phosphorous for all examined sites. As for the potassium component, Ali Al- Sharqi fields recorded the highest percentage, 121.2%, significant differences than other sites.

Table (2) showed the results of soil texture of the study sites, it was found that the Al-Qurna, Medina, and Al-Amara fields were silt soils, while the soil textures of Ali Al-Sharqia was clay soils, and Ali Al- Gharbi fields were clay sand soils.

#### **3.2 The total concentration of heavy metals in the soil**

The results of Table (3) showed the total concentrations of lead, cadmium, chromium, and cobalt minerals in the soil of several fields in Basra and Maysan provinces, the highest concentrations of these metals were examined in the soil of Al-Qurna fields, and reached 319.93, 10.79, 130.29 and 50.56 mg/kg, respectively, while the lowest concentrations of lead appeared in the soil of Ali Al-Gharbi fields, as it reached 159.98 mg/kg without a significant difference from the fields of Ali Al-Sharqi and Kumit, and a significant difference from the soil of the fields of the rest of the sites.

The lowest concentration of cadmium was reported in the soil of Ali Al-Sharqi fields, as it reached 3.03 mg/kg and without a significant difference from the areas of Kumit and Ali Al-Gharbi. While the chromium, the soil fields of Kumit and Ali Al-Gharbi recorded the lowest concentration 10, 88, 90 and 89 mg/kg respectively, and cobalt element was found to be the lowest total concentration in the soil of Kumait fields, as it reached 25.39 mg/kg, without significant differences were recorded between Ali Al-Gharbi and Ali Al-Sharqi.

To assess the level of pollution of heavy metals in the soil of some fields in Basra and Maysan governorates, the total concentrations of the examined metals were compared with the permissible limits for the total concentration of heavy metals in the soil according to the European Union standard 2006, it was noted that the concentration of lead, cadmium and chromium metals exceeded the permissible limit which was 100 mg/kg for lead, 3 mg/kg for cadmium and 100 mg/kg for chromium and that cobalt concentrations were within the permissible limit of 50 mg/kg with an exception for the soil of Al-Qurna fields, as it reached 50.56 mg/kg.

### 3.3 Available concentrations of heavy metals in the soil

The results of Table (4) showed the available concentrations of heavy metals lead, cadmium, chromium, and cobalt in the soils of some wheat fields of Basra and Maysan provinces, and the results indicated that the highest concentration of lead was examined in the soil of the Al-Qurna fields as it reached 37.32 mg/kg with a significant difference from the rest of the fields, while the lowest concentration was examined in the soil of Ali Al-Gharbi field (13.58 mg/kg). The highest available concentration of cadmium was found in Al-Qurna fields, and reached 1.89 mg/kg, while the lowest concentration was reported in the fields of Kumit, as it reached 0.83 mg/kg with a significant difference than those observed in other fields. The results indicated that the soil of Al-Qurna fields had the highest concentration of Cr with an average of 22.50 mg/kg, while the soil of Ali Al-Sharqi fields had the lowest concentration, as it reached 6.16 mg/kg. The cobalt was found to be high in the fields of the Al-Amarah fields 18.37 mg/kg and without a significant difference from the soil of the fields of Ali Al -Sharqi region that recorded a concentration of 16.52 mg/Kg.

The concentration of HMs, according to their availability, was as follows: Lead (21.32) > Cobalt (14.63) > Chromium (11.06) > Cadmium (1.15). As for the arrangement of the regions according to their pollution with heavy elements, they were as follows:

Lead: Al-Qurna > Al-Amara > Al-Madinah > Ali Al-Sharqi > Kumit > Ali Al-Gharbi, cadmium: Al-Qurna > Al-Amara > Al-Madinah > Ali Al-Sharqi > Ali Al-Gharbi > Kumit

Cobalt: Al- Amara < Ali Al-Sharqi > Kumit > Ali Al-Gharbi > Al-Qurna > Al-Madinah

Chromium: Al-Qurna > Ali Al- Gharbi > Al-Amara > Kumit > Al -Madinah > Ali Al-Sharqi.

Abass *et al.* (2015) showed that the concentrations of heavy elements, Lead, Cadmium, Cobalt, and Chromium exceeded the internationally permitted limits, as the concentrations of these elements were 115.00, 2.80, 10.25 and 60.50 mg/kg respectively. Al-Jabary *et al.* (2016) stated that the concentrations of lead, cadmium, cobalt, and chromium increased and exceeded the internationally permitted limits and were recorded 196.73, 6.27, 35.9 and 107.93 mg/kg, respectively. Khan *et al.* (2016) indicated that the cadmium and chromium exceeded the internationally permissible limits as it reached 0.58 mg/ kg and 50 mg/ kg, respectively. A study conducted by Al-Moussawi and Mustafa (2016) on the soil of Al-Qurna and Al-Madinah revealed the variation in the level of cadmium and lead concentrations in the soil of the study sites, which exceeded the internationally allowed limit.

### 3.4 Heavy metals content in wheat leaves

The results of Table (5) showed the content of heavy metals in the wheat leaves in some areas of Basra and Maysan governorates. The highest lead concentration was 0.175 mg/kg, which examined in the Qurna fields, followed by Amara with a concentration of 0.136 mg/kg. The lowest concentration of lead was observed in wheat leaves in the Kumit fields (0.007 mg/kg). The highest concentration of Cd was recorded in wheat leaves in Al-Qurna, with a significant difference from other fields, reaching 0.009 mg/kg. The lowest concentration of this HM was recorded in Ali Al Gharbi, which reached 0.002 mg/kg.

Kearallah *et al.* (2016), indicated that the average heavy metals of lead for the dry and rainy seasons ranges between 33.4 -35.42 mg/kg, and cadmium ranges between 3.23 -3.60 mg/kg. In a study conducted by Abu -Shanab *et al.*, (2007) on sixty-one plant species in soils contaminated with heavy elements, the content of plants from heavy elements varies, as the concentration of lead was found between 1- 508 mg/kg and cadmium 0.2-6 mg/kg.

### 3.5 Correlation between the total concentration of heavy metals and soil properties

The results of Table (6) showed the correlation coefficient analysis between the soil

characteristics and total concentration of heavy metals, a highly significant negative correlation was seen between HMs content and soil pH, as well as a significant correlation between lead and cadmium with EC. There was no significant association between heavy metals and other soil characteristics.

The results of Table (7) analyzing the correlation between the available concentration of heavy elements and soil characteristics, a significant correlation between the soil pH and lead, cadmium, and chromium available concentrations, whereas no correlation with cobalt and a significant correlation between soil EC and lead was observed and a highly significant negative correlation with the cobalt. No correlation was observed between OM and CEC with available concentrations of heavy metals, with an exception for the cobalt, which recorded a highly significant negative correlation, and no association was observed between heavy metals and major nutrients NPK.

Several studies showed the importance of soil properties and HMs availability. Vishun *et al.* (2007) concluded that the cadmium extracted from clay, sand, and calcareous soils was 8.92, 5.13, and 7.17 mg/kg soil, respectively, and that the amount of cadmium ready increased as the soil content of clay increased.

Zueng (2009) mentioned that the amount of cadmium extracted from the soil is determined by the value of the soil pH as it increases with the increase in the value of soil pH. CEPA(1994) found that high levels of organic matter encouraged the formation of cadmium complexes with organic matter in the soil. The behavior of chromium compounds in the soil is determined by the degree of soil interaction, the soil content of clay, organic matter, oxidation, and reduction effort (Kabata - Pendias and Pendias, 1992). Monday and Michael (2004) concluded that the amount of lead extracted was 98, 198, and 127 mg/kg soil in Spain with pH 7.3, 7.4, and 7.3, respectively, and different content of sand, silt, clay, and organic matter. Additionally; El khatib *et al.* (1990) found that the amount of availability of lead was determined by the quantity and quality of clay minerals, as the amount of lead in clay soil was greater than sandy soils, and this was due to the positive ion exchange capacity of the clay.

#### 4. CONCLUSIONS:

Results revealed that the concentrations of lead, cadmium, cobalt, and chromium elements had been exceeded the internationally permitted limits, and the high concentration of lead and cadmium elements in wheat leaves indicated the soil pollution with these two elements. A difference was observed in the association between heavy elements and chemical soil properties, indicating the effect of some of these properties on the readiness of heavy elements and some traits that do not affect the readiness of heavy elements in the soil.

#### 5. ACKNOWLEDGMENTS:

The authors thank Dr. Rashad Adel for the facilities in carrying out chemical analyzes. Thanks to Professor Dr. Khairallah Al-Jabri for his help in chemical and statistical analysis. Also thanked Dr. Mohamed Husain Manati, Mr. Faraj Abdul hae Alag, Mohamse Hamdan Aldaraji, and Mr. Abass Husain Minshad for the help in taking samples.

## RESUMO

Estudou-se o efeito de compostos orgânicos sintetizados de 6-hidroxi-2,2,4-trimetil-1,2-di-hidroquinolina, seus derivados e análogos hidrogenados sobre a altura de mudas de plantas lenhosas ornamentais. A altura das mudas como parâmetro morfométrico foi medida sete meses após o início do experimento. O tratamento pré-semeadura de *Rhododendron ledebourii* e *Rhododendron smirnowii*, com os compostos estudados, demonstrou que a di-hidro e a tetra-hidroquinolina com concentração de 0,1% foram os mais eficientes. As dihidroquinolinas nas concentrações de 0,05 e 0,1% demonstraram ter o efeito mais forte. As dihidroquinolinas para plantas lenhosas perenes são mais eficazes, depois as tetrahidroquinolinas. Os compostos químicos sintetizados mais eficientes para o *rododendro* contêm substituto de benzoílo. Para *Rh. ledebourii* e *Rh. smirnowii* os mais eficazes são os mesmos compostos químicos sintetizados: 6-hidroxi-2,2,4-trimetil-1,2,3,4-tetra-hidroquinolina, 6-hidroxi-2,2,4-trimetil-1,2-di-hidroquinolina e 1-benzoil-6-hidroxi-2,2,4-trimetil-1,2-di-hidroquinolina com concentrações de 0,01, 0,05 e 0,1%. Estes compostos, quando aplicados com o tratamento de *Rh. ledebourii* e *Rh. smirnowii* antes da sementeira, resultam em um aumento na altura das mudas em 3,6-89,3% e 14,3-57,1%, respectivamente. O efeito de compostos químicos sintetizados de 6-hidroxi-2,2,4-trimetil-1,2-di-hidroquinolina e seu análogo hidrogenado em plantas lenhosas do mesmo gênero não é específico da espécie. Sugere-se o uso de compostos de 6-hidroxi-2,2,4-trimetil-1,2-di-hidroquinolina, seus derivados e análogos hidrogenados como estimuladores do crescimento do rododendro. Os compostos da série quinolina foram testados quanto à genotoxicidade pelo método citológico no objeto modelo (*Betula pendula*) e reconhecidos como ambientalmente amigáveis. As respostas citogenéticas para *Betula pendula* e *Rhododendron* são idênticas; portanto, os compostos positivos influenciam as células de *Betula pendula* devido ao aumento da atividade metabólica, o mesmo ocorre com o *rododendro*. Portanto, compostos orgânicos sintetizados podem ser recomendados como estimuladores de crescimento eficazes.

**Palavras-chave:** estimuladores de crescimento, compostos orgânicos sintetizados, plantas lenhosas.

## ABSTRACT

The effect of synthesized organic compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, its derivatives, and hydrogenated analogs on the height of seedlings of ornamental woody plants was studied. The height of seedlings as a morphometric parameter was measured 7 months after the start of the experiment. The pre-sowing seed treatment of *Rhododendron ledebourii* and *Rhododendron smirnowii*, with the studied compounds, demonstrated that dihydro- and tetrahydroquinoline with the concentration of 0.1% proved to be the most efficient. Dihydroquinolines at concentrations of 0.05 and 0.1% proved to have the strongest effect. Dihydroquinolines for perennial woody plants are more effective, then tetrahydroquinolines. The most efficient synthesized chemical compounds for *Rhododendron* contain benzoyl substitute. For *Rh. ledebourii* and *Rh. smirnowii* the most effective are the same synthesized chemical compounds: 6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline, 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, and 1-benzoyl-6-hydroxy-2,2,4-trimethyl-1,2-

dihydroquinoline with concentrations of 0.01, 0.05, and 0.1%. These compounds, when applied with the pre-sowing seed treatment of *Rh. ledebourii* and *Rh. smirnowii*, result in an increase in the height of the seedlings by 3.6-89.3% and 14.3-57.1%, respectively. The effect of synthesized chemical compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline and its hydrogenated analog on woody plants of the same genus is not species-specific. It is suggested using the compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, its derivatives, and hydrogenated analogs as growth stimulators for *Rhododendron*. The compounds of the quinoline series were tested for genotoxicity by the cytological method in the model object (*Betula pendula*) and recognized as environmentally friendly. The cytogenetic responses for *Betula pendula* and *Rhododendron* are identical, so positive compounds influence for *Betula pendula* cells because of increased metabolic activity means the same for *Rhododendron*. Therefore, synthesized organic compounds can be recommended as effective growth stimulators.

**Keywords:** *growth stimulators, synthesized organic compounds, woody plants.*

## АННОТАЦИЯ

Исследовано влияние синтезированных органических соединений 6-гидрокси-2,2,4-триметил-1,2-дигидрохинолина, его производных и гидрированных аналогов на высоту проростков декоративных древесных растений. Высота сеянцев как морфометрический параметр измерялась через 7 месяцев после начала эксперимента. Предпосевная обработка семян *Rhododendron ledebourii* и *Rhododendron smirnowii* изученными соединениями показала, что дигидро- и тетрагидрохинолин с концентрацией 0,1% оказались наиболее эффективными. Дигидрохинолины в концентрациях 0,05 и 0,1% оказались наиболее сильными. Дигидрохинолины для многолетних древесных растений более эффективны, чем тетрагидрохинолины. Наиболее эффективные синтезированные химические соединения для рододендрона содержат бензоильный заменитель. Для *Rh. ledebourii* и *Rh. smirnowii* наиболее эффективными являются одни и те же синтезированные химические соединения: 6-гидрокси-2,2,4-триметил-1,2,3,4-тетрагидрохинолин, 6-гидрокси-2,2,4-триметил-1,2-дигидрохинолин и 1-бензоил-6-гидрокси-2,2,4-триметил-1,2-дигидрохинолин с концентрациями 0,01, 0,05 и 0,1%. Эти соединения, когда применяются при предпосевной обработке семян *Rh. ledebourii* и *Rh. smirnowii*, приводят к увеличению высоты сеянцев на 3,6-89,3% и 14,3-57,1% соответственно. Влияние синтезированных химических соединений 6-гидрокси-2,2,4-триметил-1,2-дигидрохинолина и его гидрированного аналога на древесные растения одного и того же рода не является видоспецифичным. Предлагается использовать соединения 6-гидрокси-2,2,4-триметил-1,2-дигидрохинолина, его производных и их гидрированных аналогов в качестве стимуляторов роста рододендрона. Соединения серии хинолинов были проверены на генотоксичность цитологическим методом на модельном объекте (*Betula pendula*) и признаны экологически чистыми. Цитогенетические ответы для *Betula pendula* и *Rhododendron* идентичны, поэтому положительное влияние соединений на клетки *Betula pendula* из-за повышенной метаболической активности означает то же самое для *Rhododendron*. Поэтому синтезированные органические соединения могут быть рекомендованы в качестве эффективных стимуляторов роста.

**Ключевые слова:** *стимуляторы роста, синтезированные органические соединения, древесные растения*

## 1. INTRODUCTION

The biological effect of quinolinic compounds (Abdel-Gawad *et al.*, 2005; Shuijiang *et al.*, 2005; Williamson, Ward 2005; Denmark, Venkatraman, 2006; Shikhaliev *et al.*, 2014; Ghoneim, Assy, 2015), such as dihydro- and tetrahydroquinoline, on seed germination and the root growth of the stem cuttings of woody plants, is currently being studied (Shmyreva, 2000; Butorina *et al.*, 2002; Baranova, 2013a). Environmentally friendly quinolinic compounds (Dorey *et al.*, 2000; Butorina *et al.*, 2002; Abdel-Gawad *et al.*, 2005; El-Gazzar *et al.*, 2009; Baranova, 2013a) are widely used to produce planting material, which is then planted in

anthropogenically polluted areas (Moiseeva *et al.*, 2012a; Kalaev *et al.*, 2013). It was demonstrated that depending on their concentrations, and quinolinic compounds have a different effect on seed germination and the height of the seedlings of the woody plants of *Rhododendron* L genus (Moiseeva *et al.*, 201a; Kalaev *et al.*, 2013). This means that the same quinolinic compounds at different concentrations may either stimulate or inhibit the biological processes (Dlugosz, Dus, 1996; Gavrilov *et al.*, 1988; Litvinov, 1998; Dorey *et al.*, 2000; El-Sayed *et al.*, 2002a,b, 2004; Saudi *et al.*, 2003; Brown *et al.*, 2004; van Straten *et al.*, 2005; Takahashi *et al.*, 2006, 2007; Le *et al.*, 2007; Balalaie *et al.*, 2008; Trivedi *et al.*, 2008; Fotie *et al.*, 2010). Thus, 1,2-dihydroquinoline-6-oles and

their ester derivatives were biologically (antitrypanosomally) active at micromolar concentrations (Fotie *et al.*, 2010). It was also determined, that 6-oxy-2,2,4-trimethyl-1,2-dihydroquinoline and 6-oxy-2,2,4-trimethyl-1,2-tetrahydroquinoline at concentrations of 100, 50, 25, 12.5, and 6.25  $\mu\text{g ml}^{-1}$  demonstrate bactericidal and bacteriostatic activity against laboratory *M. tuberculosis* H37 Rv indicator (the sample was provided by the museum of the local TB dispensary) and are thus highly effective antituberculous compounds (Litvinov *et al.*, 2009). In terms of percentages, the following concentrations are effective: 0.01, 0.005, 0.0025, 0.00125, and 0.000625%. It is, therefore, interesting to study the effect of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, 6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline, and their derivatives on woody plants with concentrations between 0.01–0.1%. Due to its importance as substructures in a wide range of natural and designed products, still, great efforts continue to be directed to the development of new quinoline-based structures (Li *et al.*, 1985; Mohammed *et al.*, 1992; Jain *et al.*, 1994; Croisy-Delcey *et al.*, 2000; Abadi, Brun, 2003; Shujang *et al.*, 2005; Elkholy, Morsy, 2006; Marjani *et al.*, 2011; Mosalam *et al.*, 2011a,b; Azizian *et al.*, 2014; Ghoneim, Assy, 2015; Manahelohe *et al.*, 2015a,b).

In all the existing studies, the effect of quinolinic compounds on the growth of the sprouts of woody plants was assessed on the 20th day of the experiment (Moiseeva *et al.*, 2012a, Kalaev *et al.*, 2013). However, the effect of synthesized chemical quinolinic compounds in the later stages of woody plant development (7 months after the start of the experiment) has not been studied yet. It is therefore of great importance to conduct a longitudinal study and measure the height of ornamental woody plants over longer time intervals (e.g., 7 months after the application of the growth regulator) in order to determine whether the growth stimulating effect lasts or deteriorates over time. It should be noted that the effect of the same factor may be species-specific for different plants, which makes it significantly more difficult to determine the optimal concentrations of the compounds. Seed progeny, sprouts, and even adult plants may react differently to the stimulators, which are, in fact, stress factors of various intensity.

Highly decorative species of *Rhododendron* genus have also become more popular lately (Baranova *et al.*, 2018; Burmenko *et al.*, 2018a,b). They are planted in urban and residential areas, and their propagation requires additional

stimulators of growth and seed germination.

Therefore, the aim of our research was to study the effect of synthesized organic compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, its derivatives, and hydrogenated analogs on the height of seedlings, when used for pre-sowing seed treatment of the following ornamental woody plants – *Rhododendron ledebourii* and *Rhododendron smirnowii*.

## 2. MATERIALS AND METHODS

In this study, it was used the following ornamental plants: woody plants *Rhododendron ledebourii* Pojark. And *Rhododendron smirnowii* Trautv. *Rhododendron ledebourii* is a perennial plant endemic for Altai and Mongolia. *Rhododendron smirnowii* is native to the forests and mountains of Caucasus, Adjara, and Turkey. *Rhododendron ledebourii* is a semi-evergreen shrub, and *Rhododendron smirnowii*, an evergreen shrub. In a controlled environment, both species grow up to 2-meter height and are highly decorative (Alexandrova, 2003). The long history of studying these species at the B.M. Kozo-Polyansky Botanical Garden of Voronezh State University has demonstrated that *Rhododendron ledebourii* is a winter-hardy, drought-resistant, and fruit-bearing shrub (Moiseeva *et al.*, 2012b; Baranova 2013b). *Rhododendron smirnowii* is also quite winter-hardy, though less drought-resistant. It also grows slower than *Rhododendron ledebourii* (Alexandrova, 2003; Vostrikova, 2011).

The research was conducted at the B.M. Kozo-Polyansky Botanical Garden of Voronezh State University in 2017. The study focused on the following organic compounds synthesized at the Department of Organic Chemistry of Voronezh State University:

6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline (stimulator 1),

6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline (stimulator 2),

7-[(dimethylamino)methyl]-6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline (stimulator 3),

7-[(dimethylamino)methyl]-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline (stimulator 4), and

1-benzoyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline (stimulator 5), and the way they influence the height of the seedlings of *Rh. ledebourii* and *Rh. smirnowii*.

The stimulator 1 (6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline) and stimulator 2 (6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline) were synthesized from commercially available 6-ethoxy-2,2,4-trimethyl-1,2-dihydroquinoline (ethoxychine) by the known method (Ivanov *et al.*, 1979). By aminomethylation of stimulators 1 and 2 with bis(dimethylamino)methane resulted in stimulator 3 (7-[(dimethylamino)methyl]-6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline) and stimulator 4 (7-[(dimethylamino)methyl]-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline), respectively. The stimulator 5 (1-benzoyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline) was obtained as a result of successive reactions of acylation of stimulator 2 an excess of benzoyl chloride and subsequent alkaline hydrolysis of the

resulting diacyl-derivative.

Prior to the sprouting process, the seeds of *Rh. ledebourii*, *Rh. smirnowii* were soaked in water solutions of the above-listed compounds with concentrations of 0.01%, 0.05%, and 0.1% for 18 hours. The control group consisted of the same type of seeds soaked in a tap water solution of a commonly used growth stimulator, Epibrassinolide (commercial fraction *Epin Extra* produced by NNPP NEST M, Russia), with the concentration of 0.05% (in accordance with the instruction). In the case of each of the studied concentrations of the acids, as well as the control group, the experiment was conducted three times using a set of 100 seeds. After soaking, the rhododendron seeds were placed in Petri dishes containing blotting paper and germinated in the laboratory conditions at a constant temperature of 22 °C. On the 21st day, the sprouts were planted in containers filled with high-moor peat and then kept in a greenhouse. The height of the seedlings of *Rhododendron* was measured with a ruler, 7 months after the start of the experiment. Sprouts are formed during the early stage of plant ontogenesis, which starts after the germination stage, i.e., when the seed coat develops, and finishes when the first leaf of the hypocotyledonous stem (the shoot rising from the plumule) develops (Korovkin, 2007). After the first true leaves appear, young plants are considered seedlings (Korovkin, 2007). The results were statistically processed using the STADIA software package. The procedures of data grouping and processing were described by A. P. Kulaichev (2006). The mean values were compared using Student's t-test. The variances were compared using the F-test.

### 3. RESULTS AND DISCUSSION:

The results of the treatment of seeds with the chemical compounds on the height of *Rh. ledebourii* seedlings 7 months after the start of the experiment are given in Table 1 and in Figure 1. It demonstrates that 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline (stimulator 2) appears to have strong stimulating effect with any of the studied concentrations: 0.01, 0.05, and 0.1% (differences with the control group are reliable,  $p < 0.001$ ). Dihydroquinolines (stimulators 4 and 5) and their substitutes 7-[(dimethylamino)methyl]- and especially 1-benzoyl- proved to have the stimulating effect at any of the studied concentrations (Table 3). 6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline (stimulator 1)

and 7-[(dimethylamino)methyl]-6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline (stimulator 3) appeared to be less active. 7 months after the start of the experiment, the height of *Rh. ledebourii* seedlings increased by 17.9–89.3% (Table 3).

For *Rh. smirnowii*, 7 months after the seed treatment with the studied chemical compounds, the concentration of 0.1% proved to be the most effective (Table 2, Fig. 2) and increased the plants' height of 57.1–14.3% (Table 4).

The effect of certain quinolines on seed germination and the size of seedlings of *Rh. Ledebouriionon*, the 20th day of the experiment was investigated earlier. It was demonstrated that 2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline and 2,2,4-trimethyl-1,2-dihydroquinoline (with a concentration of 0.1%) have a stimulating effect on both the seed germination and the height of the sprouts of *Rhododendron ledebourii* (Moiseeva *et al.*, 2012a; Kalaev *et al.*, 2013).

Besides *Rh. ledebourii*, 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline also had the strongest stimulating effect on *Rh. smirnowii* (Table 2). 7 months after the start of the experiment, the height of *Rh. smirnowii* seedlings increased by 21.4–57.1% (Table 4). 6-Hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline was less effective, with the increase in the height of the seedlings (as compared to the control group) being 14.3–28.6% (Table 2, 4). 1-Benzoyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline at concentrations of 0.05 and 0.1% (Tables 2, 4) also demonstrated a stimulating effect.

Thus, dihydroquinolines appear to have the strongest stimulating effect, with benzoyl boosting the effect of the stimulator, while tetrahydroquinolines are less active. Previous studies have determined that the detected antitrypanosomal activity of 1,2-dihydroquinoline-6-oles and their ester derivatives at micromolar concentrations are higher in the compounds containing benzene substitutes for the nitrogen atom (Fotie *et al.*, 2010). However, the latter have different cytotoxicity. 1-benzyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline acetate (I) (1-benzyl--6-hydroxy-1,2-dihydro-2,2,4-trimethylquinolin-6-yl acetate) was the most effective and had low cytotoxicity. Its activity involves the formation of the precursor 1-benzyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline (1-benzyl--6-hydroxy-1,2-dihydro-2,2,4-trimethylquinolin) (II) (Fotie *et al.*, 2010), which is the structural analogue of 1-benzoyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline (1-benzyl--6-hydroxy-1,2-dihydro-2,2,4-trimethylquinolin)

(stimulator 5) we used in our study (Fig. 3) (Fotie *et al.*, 2010).

For the plants of *Rhododendron* L. genus, the strongest stimulating effect was demonstrated by all the studied compounds with a concentration of 0.1%.

For *Rh. ledebourii* and *Rh. smirnowii* the most effective are the same synthesized chemical compounds: 6-hydroxy-2,2,4-trimethyl-1,2,3,4-tetrahydroquinoline, 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, and 1-benzoyl-6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline with concentrations of 0.01, 0.05, and 0.1%.

#### 4. CONCLUSIONS:

For the studied species of *Rhododendron* genus, the compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, its derivatives, and hydrogenated analogs with the concentration of 0.1% proved to be the most efficient. Dihydroquinolines with concentrations of 0.05 and 0.1% appear to have the strongest stimulating effect on perennial woody plants, with benzoyl boosting the effect of the stimulator, while tetrahydroquinolines are less active. The effect of synthesized chemical compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline and its hydrogenated analog on woody plants of the same genus is not species specific. These compounds, when applied with the pre-sowing seed treatment of *Rh. ledebourii*, *Rh. smirnowii* result in an increase in the height of the seedlings by 3.6–89.3%, 14.3–57.1%, respectively. Thus it is suggested using the compounds of 6-hydroxy-2,2,4-trimethyl-1,2-dihydroquinoline, its derivatives, and hydrogenated analogs as growth stimulators for ornamental woody plants. The compounds of the quinoline series were tested for genotoxicity by the cytological method in the model object (*Betula pendula*) and recognized as environmentally friendly (Butorina *et al.*, 2002). The cytogenetic responses for *Betula pendula* and *Rhododendron* are identical, so positive compounds influence for *Betula pendula* cells because of increasing of metabolic activity means the same for *Rhododendron* (Baranova *et al.*, 2018; Burmenko *et al.*, 2018a,b). Therefore, synthesized organic compounds can be recommended as effective growth stimulators.

## RESUMO

O barrigudinho, *Poecilia reticulata*, é um modelo para muitos estudos ictiológicos. Foi estudado o efeito da luz no crescimento juvenil da *Poecilia reticulata*. Estudos foram realizados em aquários de vinte litros. Para experimentos sobre a escolha arbitrária da intensidade da luz (comportamento da transmissão da luz), foram utilizados aquários radiantes de vidro orgânico medindo 150x15x15 cm, divididos com semi-divisórias transparentes em dez compartimentos de comunicação. A taxa de crescimento específica foi determinada após as experiências. A taxa de crescimento eleva-se com o aumento do nível de luz. A taxa de crescimento é mínima em 0 lx em todas as séries de experimentos. Foi demonstrado que o aumento mais acentuado na taxa de crescimento específico dos barrigudinhos ocorreu quando a iluminação mudou de 0 para 200 lx. Um aumento adicional na intensidade da iluminação praticamente não afetou o crescimento dos barrigudinhos. Além disso, o comportamento juvenil dos barrigudinhos foi estudado em bandejas especiais com luz diferente de 3200 a 5900 lx. A atividade motora dos barrigudinhos aumenta em 30% em condições de gradiente de luz. A frequência (25 s) e a duração dos barrigudinhos (28,3 s) são as mais altas do compartimento, com 4700 lx. A zona de luz preferencial se expande se os jovens estiverem passando fome. À medida que o período de fome aumentava, os barrigudinhos começaram a nadar com frequência quase igual e a permanecer em diferentes zonas de luz. Assim, condições de alta luminosidade estimulam o comportamento de busca e a atividade dos barrigudinhos. Para criar barrigudinhos em condições de produção, é necessária alta iluminação.

**Palavras-Chave:** Luz, Iluminação, *Poecilia Reticulate*, Crescimento, Comportamento.

## ABSTRACT

The guppy, *Poecilia reticulata*, is a model for many ichthyological studies. The effect of light on juvenile growth has been studied on the *Poecilia reticulata*. Studies have been conducted in twenty-liter aquariums. For experiments on the fish arbitrary choice of light intensity (light transmission behavior), it was used radiant pans of organic glass 150 x 15 x 15 cm divided by transparent semi-partitions into ten communicating compartments. The specific growth rate has been determined after the experiments. It increases with the light level increasing. The growth rate is minimal at 0 lx in all series of experiments. It was shown that the sharpest increase in the specific growth rate of guppies occurred when the illumination changed from 0 to 200 lx. A further increase in the intensity of illumination practically did not affect the growth of guppies. Also, the guppy juvenile behavior has been studied in special trays at different light from 3200 to 5900 lx. The motor activity of guppies increases by 30% in light-gradient conditions. The frequency (25 sec) and length of guppies stay (28.3 sec) are the highest in the compartment with 4700 lx. The preferential light zone expands if the juveniles are starving. As the period of starvation increased, guppies began to swim almost equally often and linger in different light zones. Thus, high light conditions stimulate the search behavior and activity of guppies. To grow guppies in production conditions, high illumination is necessary.

## АННОТАЦИЯ

Гуппи (*Poecilia reticulata*) является модельным объектом многих ихтиологических исследований. На этом объекте изучали как воздействует освещенность на рост мальков. Исследования проводили в 20-литровых аквариумах. Для экспериментов по произвольному выбору рыбой интенсивности света (светогradientного поведения) мы использовали прозрачные лотки из органического стекла 150\*15\*15 см, разделенные прозрачными полуперегородками на десять сообщающихся отсеков. После экспериментов определяли скорость роста. Скорость роста повышалась при увеличении уровня освещенности. При 0 лк скорость роста была минимальной во всех сериях экспериментов. Было показано, что наиболее резкое возрастание удельной скорости роста мальков гуппи происходило при изменении освещенности от 0 до 200 лк. Дальнейшее увеличение интенсивности освещения практически не оказало воздействие на рост гуппи. Также исследовали поведение мальков гуппи в специальных лотках при различной освещенности от 3200 до 5900 лк. Двигательная активность гуппи в светогradientных условиях возрастала на 30%. Частота и длительность пребывания гуппи были наивысшими в отсеке с освещенностью 4700 лк 25 и 28.3 с, соответственно. У голодных особей преферентная зона освещенности расширялась. По мере увеличения периода голодания особи гуппи начинали практически одинаково часто заплывать и задерживаться в различных по освещенности зонах. Таким образом, высокая освещенность стимулирует поисковое поведение и активность гуппи. Для выращивания гуппи в производственных условиях необходима высокая освещенность.

**Ключевые слова:** Свет, Освещенность, *Poecilia reticulata*, Рост, Поведение.

## 1. INTRODUCTION

The *Poecilia reticulata*, popular aquarium fish, is a traditional subject of laboratory studies. Guppies live in freshwater both in mountain rivers and in muddy warm water) and in the saltish waters of Venezuela, Guyana, Trinidad, Barbados, Martinique as well as in some parts of northern Brazil (Echevarría and González, 2018). According to Ahmed et al. (1985), it has been found to establish itself in both fresh and polluted waters. In particular, it is used to conduct ethological studies (Fraser and Gilliam, 1987; Abrahams and Dill, 1989; Morrell et al., 2008), to study color and light perception (Smith et al., 2002; Sakai et al., 2016) as well as reproductive behavior (Reeve et al., 2014) and parasitological studies (Gotanda et al., 2013).

Light creates the necessary existence conditions, makes it possible to orient oneself in the environment for many aquatic organism species (Konstantinov et al., 2000; Ruchin et al., 2005; Ruchin, 2007, Ruchin, 2020). Illumination is an important environmental factor that affects different aspects of aquatic animals' existence. Specific environmental conditions have a positive effect on fish and amphibians (Boeuf and Le Bail, 1999). For example, growth of *Epinephelus coioides* yearlings improves with 320-1150 lx illumination (Wang et al., 2013), growth of juvenile *Megalobrama amblycephala* improves with 400 lx (Tian et al., 2015), growth of *Acipenser baerii* juveniles improves with 30-800 lx (Ruchin, 2008), growth of *Salmo salar* juveniles improves with 21-650 lx illumination (Handeland et al., 2013).

According to Toledo et al. (2002), Bădiliță et al. (2010), Ruchin (2016), Ruchin (2018), the embryonic development of fish and amphibians needs specific illumination parameters. Russian biologists such as Ruchin (2000), Ruchin (2004), Kuznetsov, and Ruchin (2001) proved that the larval development of several amphibian species accelerates with illumination above 1000 lx. Inhibition of growth, development, and survival of many species of aquatic vertebrate animals is observed outside of this illumination. Our research is aimed to study the light effect on the guppy growth and behavior.

## 2. MATERIALS AND METHODS

The experiments were conducted in 20 L aquariums. Fluorescent lamps emitted illumination. The intensity of illumination was measured with the U-116 lux meter. In the darkness (0 lx), aquariums were closed with an opaque cover. In each series of experiments, we used one female juvenile. Every time we placed 10–20 juveniles and weighed them at the beginning and the end of the experiment with an accuracy of 0.01 mg (Figure 1). We fed them continuously with zooplankton, and *Artemia* decapsulated eggs. The duration of the experiments ranged from 10 to 20 days. Experiments were repeated from five to nine times. Growth parameters were calculated as follows (Eq. 1):

$$\text{SGR } (\% \text{ day}^{-1}) = \frac{\ln W_f - \ln W_i}{t} \times 100 \quad (\text{Eq. 1})$$

where SGR is the *Specific Growth Rate*.

For experiments on the fish arbitrary choice of light intensity (light transmission behavior), we used radiant pans of organic glass 150 x 15 x 15 cm divided by transparent semi-partitions into ten communicating compartments (Ruchin, 2019). There was emitted a light gradient from 3200 lx at the beginning of the tray to 5900 lx at its end. The illumination in the control corresponded to the average value of the illumination in the experimental tray (4550 lx). We conducted observations in the morning at a temperature of 24 °C. We placed there three or four immature females weighing 9–12 g. We were watching one fish for 10–20 minutes a day. The experiments were repeated ten times. We also conducted research on well-fed and starving individuals. We investigated the options: 1 – well-fed, 2, 3, and 4, respectively, 0.5, 2, and 24 hours after the food's withdrawal.

Based on statistical data, we calculated the average duration of a single fish stay in a particular compartment ( $\tau$ , sec), the swims' number in each compartment ( $n$ ), and the total time of fish stay in each compartment ( $\sum \tau$ , min). All values were reduced to one hour (Ruchin, 2001a). The swimming distance from the beginning of the movement to the turn in the opposite direction was called "single-vector" and was designated as  $S_v$ . We calculated the duration of the continuous single-vector displacement ( $\tau_v$ ) because the motion in the gradient is discrete. Moreover, we noted the total number of single-vector displacements ( $N$ ). Knowing their average length ( $S_v$ ), we calculated the total path traversed by fish per hour as well as calculated the speed of movements ( $S_v/\tau_v$ ), the total time of movements, and the total time of fish delays in the compartments. According to Konstantinov and Zdanovich (1993) and Ruchin (2019), the use of these indicators makes it possible to characterize the fish behavior in gradient conditions more differentiated.

Data between treatments and sampling times were compared by analysis of variance (ANOVA). The data were statistically processed using a standard method with Student's Test.

### 3. RESULTS AND DISCUSSION

Figure 2 shows that the growth rate of guppy juveniles gradually increases with the light increase. Earlier, Ruchin (2001b) obtained similar results in experiments on carp larvae. As we can

see, the specific growth rate of guppy juveniles appeared when the illumination changes from 0 to 200 lx. A further increase in the intensity of illumination had practically no effect on the growth. In some experiments, the maximal increments were noted with 4500 lx and 11500 lx. There was no significant difference between them. In other experiments, in the absence of light (0 lx), the increments were minimal. The survival rate in all experiments was 100%, and we did not register the death.

Analysis of the fish behavior in the light gradient field showed that the juveniles stayed principally in areas with a certain light level. However, they often swam for short periods in compartments with different light values (Table 1).

The frequency (25 s) and duration (28.3 s) of guppy's stay were highest in the compartment with illumination 4700 lx. Table 1 shows that juveniles moved without a definite pattern in the control with balancing illumination, but they lingered in the last compartments. In other words, the "edge" effect appeared in the control. This effect was not registered with light gradient conditions. Individuals began to swim almost equally often and lingered in zones with different illumination as the starvation period increased. For example, the duration of one-time stay of starvation (0.5 hours) individuals with an illumination 4100–5300 lx was 35.3–21.2 s. Two hours after the food absence, the preferential zone expanded to 3800–5600 lx ( $t = 25.0$ –36.3 s), and after 24 hours of fasting, the juveniles stayed almost the same time in all compartments.

Table 2 shows that the motor activity of juvenile guppies in light-gradient conditions was higher in control by 30%. If the number of vector displacements did not differ, in the light gradient, the average displacement distance and the total path were higher by 15% and 18% than the corresponding values in the control with uniform illumination. Consequently, the total time of movement in the experiment exceeded this value with balancing illumination.

Thus, fish motor activity increased due to the increase in the range of movement and swimming speed in a gradient field. Juvenile behavior analysis in the gradient field of the factor shows that the preferential zones vary depending on the period of lack of food. The zone of the preferendum is shifted towards higher illumination values.

It was found that the growth of juveniles was characterized by an optimal range of illumination. Referring to the researches of Trippel

and Neil (2003), Suzer *et al.* (2006), Ruchin (2008), it was concluded that bottom dwellers needed lower luminance values and pelagic fish, including guppies, needed higher luminance (Ruchin, 2001b; Pereira-Davison and Callan, 2018; Jirsa *et al.*, 2009; Wang *et al.*, 2013). The sharply negative effect of zero light on growth (0 lx) was common to all of these fish species.

Many researchers studied fish behavior in various light conditions. Winslade (1974) proved that the juvenile *Ammodytes marinus* possessed positive phototaxis as well as *Cyprinus carpio* and *Carassius auratus* (Ruchin, 2001a) and the atherin *Leuresthes tenuis* (Reynolds *et al.*, 1977). Meanwhile, Britz and Pienaar (1992) revealed that *Clarias gariepinus* had negative phototaxis. Confer *et al.* (1978), Macy *et al.* (1998), Ryer and Olla (1999) showed that light intensity could influence prey selection and consumption rates. According to Keyler *et al.* (2015), food consumption increases with the light intensity. It means that planktonophagous foraging for food (plankton) is oriented toward illumination. Consequently, differences in illumination stimulate guppies to search for food and increase the juvenile activity. Guppy belongs to planktophagous, so its individuals searching for food focus on the light. Although White *et al.* (2005), did not reveal any peculiarities in food consumption. Jain and Sahai (1994), White *et al.* (2005), Barki *et al.* (2013) also indicated a positive phototaxis of different ages guppies.

#### 4. CONCLUSIONS

The obtained results confirm that the appropriate light intensity is needed for guppies growing. The growth of this juvenile species improves with very high values of illumination in a wide range of illumination from 1500 lx to 11500 lx. However, to save energy resources, the authors recommend lighting up 2000-2500 lx for juveniles growing.

### RESUMO

O artigo examina a poluição química do rio Iori, um dos rios mais importantes da Geórgia. Além da Geórgia, este rio é presente no Azerbaijão. O estudo desse rio é crucial, pois a LLC *United Water Supply Company* da Georgia organiza o abastecimento de água das grandes cidades e vilas da Geórgia através da água do Iori. Além disso, a população de duas grandes aldeias usa independentemente a água do rio para várias atividades domésticas: lavagem (lavanderia, produtos, louças), fornecimento de água para animais e irrigação. Não sendo utilizada diretamente como água potável. A água do rio Iori foi monitorada em duas seções: vila Sasadilo e vila Sartichala. No total, foram coletadas 24 amostras ao longo dos anos de 2018 e 2019. Alguma parte da pesquisa foi realizada no local através do instrumento HI83399-02 | Multiparâmetro para água e esgoto (com COD) Fotômetro e medidor de pH. Esses estudos incluíram pH, DBO e a temperatura foi medida diretamente durante a amostragem. O mesmo dispositivo foi usado para medir concentrações aproximadas de metais pesados. Na etapa seguinte do estudo, foi realizada uma pesquisa entre os habitantes para identificar seus conhecimentos sobre questões de limpeza e segurança ambiental. Como resultado do estudo, foi recomendado para a população abster-se ou restringir o uso de água do rio não tratada diretamente nas domesticidades. Os resultados da pesquisa mostraram que a população tem menos informações sobre a probabilidade de reter metais pesados no corpo e desenvolver doenças tumorais.

**Palavras-chave:** *Poluição da água, Contaminantes, Bacia hidrográfica, Produtos químicos tóxicos, pesquisa de habitantes.*

### ABSTRACT

The article examines the chemical pollution of the Iori River, one of the most important rivers in Georgia. In addition to Georgia, this river is found in Azerbaijan. The study of this river is crucial as LLC *United Water Supply Company* of Georgia organizes the water supply of big cities and villages of Georgia through Iori water. Furthermore, the population of two big villages independently uses the river water for various household activities: washing (laundry, products, dishware), livestock watering, and irrigation. They do not use it as drinking water. The water of the Iori River was monitored in two sections: village Sasadilo and village Sartichala. In total, 24 samples were taken over the course of 2018 and 2019 years. Some part of the research was conducted on the site through HI83399-02 | Water & Wastewater Multiparameter (with COD) Photometer and pH meter device. These studies included pH, BOD, and the temperature was measured directly during sampling. The same device was used for measuring approximate concentrations of heavy metals. At the next stage of the study, an inhabitants survey was conducted to identify their knowledge of environmental cleanliness and safety concerns. As a result of the study, our recommendation to the population is to refrain or restrict the use of untreated river water directly in domesticities. The results of the survey showed that the population has less information about the likelihood of getting heavy metals in the body and developing tumor diseases.

**Keywords:** *Water pollution, Contaminants, River basin, Toxic chemicals, inhabitants survey.*

## 1. INTRODUCTION:

Recent developments have made it clear that human health, the stability of the country, and the stability of the world may be threatened by various epidemics. The cleanliness of water resources is of particular importance in terms of the spread of various poisonous contaminants. Even if a disease-causing agent is transmitted by airborne droplets, frequent hand washing is recommended according to the recommendations issued by the World Health Organization, 2017. Moreover, for this, clean water is needed (Matthew, Freeman, 2017; Sharma, Bhattacharya, 2017; Daughton, 2004).

Added to this is the growing shortage of freshwater on the planet. Increased demand for global water threatens biodiversity and water supply for food production, other vital human needs. Water scarcity already exists in many regions of the world, with more than one million people left without drinking water (Lomsadze, Makharadze, 2016; Sammons, Maceina, 2009; Danyer, Arda, 2018). Also, 90% of infectious diseases in developing countries are transmitted by water, because in some cases, contaminated water is used for drinking and washing. Sometimes the problem is that people do not have complete information about the dangers of polluted water and they use it.

Consequently, the cleanliness and monitoring of the country's surface waters, i.e., rivers and lakes, take on enormous importance. Especially if the river water is used by inhabitants (Kupatadze, Kiziloz, 2019; Kupatadze, 2018; Abhijit, Ranju, 2012).

Georgia is rich in rivers and lakes, the water of which is used by the population to drink, prepare food, wash products, do housework, and irrigate. See the list of the main rivers of Georgia in Table 1.

This time, the purpose of our research was to study the chemical composition and the degree of water pollution in the Iori River.

Currently, LLC United Water Supply Company of Georgia (<http://water.gov.ge/eng/>) operates all over the area of Alazani and Iori, organizing water supply for large cities and villages.

Surface and underground waters are used for water supply. However, their quantity is not enough for the population today. Therefore, in near-by medium-sized villages, water obtained directly from the river, the so-called Rural Water, though not for drinking, is used for all the rest needs. It is used for washing dishes, fruits, vegetables, and other food products, as well as for irrigation.

For this very reason, monitoring of the degree of pollution is essential.

**Iori** (Fig.1) is the river flowing in Georgia and Azerbaijani. It originates on the southern slope of the Caucasus, near the peak Borbalo, at an altitude of 2600 m above sea level. In the upstream, it flows into the gorge, in the middle, it crosses the Samgori Cave, ultimately joining the Mingachevir reservoir. In the past, Iori used to join the Alazani River on the right side. It is fed from snow and rain waters. Iori has South-East direction. In the beginning, Iori Valley has the shape of a narrow and deep mountain valley, then it passes into Tianeti Valley, with two tributaries flowing into it, ending in the Zion Valley, where the Sioni Reservoir is located. Iori River divides Iori Plateau into two parts: Iori-Alazani and Iori-Mtkvari. On the left bank of the Iori River, humus-sulfate, and saline soils are widespread (Pistric, Klaus, 1989; William, David, 1971).

There is a regulating Sioni Reservoir constructed on the Iori River. Tbilisi Reservoir or "Tbilisi Sea" was formed by Iori water. Dali Mountain Reservoir is constructed in the downstream of the Iori River, with a water volume of 140.0 km<sup>3</sup>. More than 90 thousand hectares are irrigated by the Iori River on the Iori plateau. Several irrigation systems have been built on the river, central of which are the upper and lower water mains.

**Figure 1.** Iori river

## 2. MATERIALS AND METHODS:

The water of the Iori River was monitored at 2 sections: village Sasadilo and village Sartichala. In total, 24 samples were taken over the course of 2018 and 2019 years. Some part of the research was conducted on the site through HI83399-02 Water & Wastewater Multiparameter (with COD) Photometer and pH meter device. These studies included pH, BOD, and the temperature was measured directly during

sampling. The same device with special analytical reagents (HI-93746-03, HR-HI-93709-01HR, HI-93721-01, HI-93731-01, HI-93737-03) was used for measuring approximate concentrations of heavy metals (Pb, Mn, Fe, Zn, Cu).

It is very convenient to use the above-mentioned equipment to do the analysis directly from the source of research material (directly from the river in our case). This photometer features an innovative optical system that uses LEDs, narrow band interference filters, focusing lens, and both a silicon photodetector for absorbance measurement and a reference detector to maintain a consistent light source ensures accurate and repeatable photometric readings every time. Selecting the pH measurement mode allows for the photometer to be used as a professional pH meter with many features, including temperature compensated measurements, automatic two-point calibration.

Analysis for defining the ammonium nitrogen were also performed with HI83399-02 | Water & Wastewater Multiparameter using appropriate reagents. Analysis of total alkalinity and acidity, cations, and anions were performed in the laboratory of Ilia State University. Their protocols are based on the methodology of analytical chemistry, mainly on qualitative (colorimetric) and quantitative analysis (titrimetric).

Alkalinity is a measure of a river's "buffering capacity" or its ability to neutralize acids. Alkaline compounds in the water, such as bicarbonates, carbonates, and hydroxides, remove H<sup>+</sup> ions and lower the acidity of the water (which means increased pH). This is usually done by combining with the H<sup>+</sup> ions to make new compounds. Without this acid-neutralizing capacity, any acid added to a river would cause an immediate change in the pH. Measuring alkalinity is important to determine a river's ability to neutralize acidic pollution (as measured by pH) from rainfall or snowmelt. It's one of the best measures of the sensitivity of the river to acid inputs. Alkalinity comes from rocks and soils, salts, certain plant activities, and certain industrial wastewater discharges. The result is reported as milligrams per liter (mg/l) of calcium carbonate.

Acidity is the quantitative expression of water's capacity to neutralize a strong base to a designated pH and an indicator of how corrosive water is. Acidity can be caused by weak organic acids, such as acetic and tannic acids, and strong mineral acids, including sulfuric and hydrochloric acids; however, the most common source of acidity in unpolluted water is carbon dioxide in the

form of carbonic acid. Standard Methods for the Examination of Water and Wastewater (Standard Methods) recommends titration with sodium hydroxide to an endpoint pH of 3.7 to determine mineral acidity. Titrate to pH 8.3 to determine total acidity (Bhatia, 2013; Lopes, 2017; VanLoon, 2011; Sutton, 2008; Rawn, 2004).

In general, the existence of an ecologically educated population is vital (Lui, 2009; Cross, 2007; Henjum, Barikkmo, 2010). Therefore, in parallel with sampling and analysis, we conducted the inhabitant survey. See the questions in Table 2.

### 3. RESULTS AND DISCUSSION:

In general, the oxygen content in the samples taken was satisfactory. BOD varied within 0.64 – 1.83 mg/l. The nitrogen content of ammonium ranged from 0.016 to 1.672 mg N/l and exceeded the maximum allowable value in five samples. Its average annual concentration was 0.348 mg N/l. The maximum value of 1.672 mg N/l (4.3 maximum allowable concentration (MAC) was observed in January 2019). Mineralization ranged from 203.34–429.65 mg/l. The maximum value 429.65 mg/l was registered in Sartichala. The maximum concentrations of iron and manganese in just one sample exceeded the allowable value. Iron levels ranged from 0.0455 to 4.1684 mg/l. Its average annual concentration amounted to 0.8106 mg/l (2.1 MAC). The maximum value 4.1684 mg/l (13.9 MAC) was registered in September of 2019 by village Sartichala.

It should also be noted that iron (II) compounds are mainly found in groundwater. They are found in water as a result of iron-containing rocks washed out by acids. These acids may be carbonic dioxide or humic acid.

Iron (III) compounds are present in surface waters, however, not in large quantities. They are formed by hydrolysis of salts. Iron ions in water are mainly composed of complexes formed with humic acid, and such water is slightly brown if the content of iron ions exceeds 0.3 mg/l, the water tastes of iron.

The manganese content ranged from 0.0032–0.5974 mg/l. Its average annual concentration amounted 0.1057 mg/l (1.1 MAC). The maximum value of 0.5974 mg / l (6.0 MAC) was observed in September 2019. Concentrations of nitrite and nitrate nitrogen, phosphates, sulfates, chlorides, lead zinc, and copper did not exceed the maximum allowable concentrations.

A total of 12 samples were taken from the lori River, in Sartichala village (Table 3). The oxygen content was satisfactory. BOD varied within 0.64–1.83 mg/l. The nitrogen content of ammonium ranged from 0.047 to 1.672 mg N/l. Its average annual concentration reached 0.445 mg N/l (1.1 MAC). The maximum value of 1.672 mg N/l (4.3 MAC) was observed in January. Mineralization ranged from 231.01–429.65 mg/l. The maximum value was 429.65 mg/l in May. Iron content ranged from 0.0901–4.1684 mg/l. Its average annual concentration was 1.4976 mg/l (5.0 MAC). The maximum value of 4.1684 mg/l (14 MAC) was observed in September. The manganese content ranged from 0.0086–0.5974 mg/l. Its average annual concentration was 0.2068 mg/l (2.1 MAC). The maximum value of 0.5974 mg/l (6.0 MAC) was observed in September. Concentrations of nitrite and nitrate nitrogen, phosphates, sulfates, chlorides, lead, zinc, and copper did not exceed the maximum allowable concentrations.

In total, 12 samples were taken from the lori River in Sasadilo village (Table 4). The oxygen content was satisfactory. BOD varied within 0.72–1.51 mg/l. The nitrogen content of ammonium ranged from 0.016 to 0.505 mg N/l. Its average annual concentration was 0.250 mg N/l. The maximum value of 0.505 mg N / l (1.3 MAC) was observed in March, and it exceeded the limit only once. Mineralization ranged within 203.34–332.32 mg/l. The maximum value was 332.32 mg / l in May. Concentrations of nitrite and nitrate nitrogen, phosphates, sulfates, chlorides, iron, lead, zinc, copper, and manganese did not exceed the maximum allowable concentrations.

As can be seen from the data, heavy metals are present in the water, albeit within the permissible norm.

According to the study (Kiziloz, 2018; Kupatadze, Kiziloz, 2019), the possible impact of heavy metals on human health can be calculated by using equation (1).

$$ADIW_{ing} = C \times IR \times EF \times ED / BW \times AT \quad (Eq.1)$$

Where,  $ADIW_{ing}$  is the average daily intake of heavy metals ingested from water (mg/kg-day),  $C$  is the heavy metal concentration in water (µg/L).  $IR$  is the daily intake of water, approx. 2l/day.  $ED$  is the exposure duration, approx. 80 years.  $EF$  is the exposure frequency, 365 days/year.  $AT$  is the period over which the dose is averaged,  $365 \times 80 = 29.200$  days.  $BW$  is the bodyweight of the exposed individual (75kg approx.).

At the same time, by Equation 2, e.g., "Hazard quotient" (HQ) can also be calculated.

$$HQ=ADI/RfD \quad (Eq.2)$$

Were, ADI is the value obtained from the previous equation. RfD is chronic reference dose values are generally calculated.

For the studied water samples, the values calculated through Equation 1 and 2 are given in Tables 5 and 6.

**Table 5.** ADIW and HQ values for some hazardous metals in lori water Sasadilo

| Ions of heavy metals | ADIWing |       | HQ     |        |
|----------------------|---------|-------|--------|--------|
|                      | 2018    | 2019  | 2018   | 2019   |
| Pb                   | 34.66   | 57.1  | 3.46   | 5.71   |
| Mn                   | 15.024  | 15.93 | 0.3004 | 0.3186 |
| Fe                   | 107.8   | 111.1 | 539    | 555.7  |
| Zn                   | 26.66   | 27.2  | 26.66  | 27.2   |
| Cu                   | 320     | 293   | 3.2    | 2.93   |

**Table 6.** ADIW and HQ values for some hazardous metals in lori water Sartichala

| Ions of heavy metals | ADIWing |       | HQ     |        |
|----------------------|---------|-------|--------|--------|
|                      | 2018    | 2019  | 2018   | 2019   |
| Pb                   | 34,6    | 74.6  | 3.46   | 7.46   |
| Mn                   | 14.17   | 15.93 | 0.2834 | 0.3186 |
| Fe                   | 107.7   | 111,1 | 538    | 555.7  |
| Zn                   | 26.66   | 27.2  | 26.66  | 27.2   |
| Cu                   | 293     | 373   | 2.93   | 3.73   |

### Inhabitant survey

At the second stage of the study, we conducted the inhabitant survey, wondering what they knew about water intake rules and clean water, what information they had about water-borne diseases, or the likelihood of causing such an incurable disease as a malignant tumor. According to the Statistics Office of Georgia, 8731 cases were registered in Georgia in 2018 and 10402 new cases - in 2019.

The results of the survey were included in

Table 7.

The survey clearly showed that the population of Sasadilo and Sartichala villages have little idea that the use of water contaminated by heavy metals, even for irrigation or washing, is linked to the development of malignant tumors.

They are more or less aware of the importance of drinking water and the daily norm of water intake. Only 20% know that water containing chlorine ions cannot be boiled twice. That is, if the water is boiled once to make tea or other hot beverages, the residual water should not be boiled again, because chlorine ions form carcinogen with chromium, which is likely to be present in water, and may trigger cancer in the body over the years.

If the water contains chlorine or the chlorine is used for water disinfection, can it still be boiled for hot drinks after boiling.

### 4. CONCLUSIONS:

Thus, the chemical composition of the water of lori River was monitored in two villages.

The study showed that the main contaminants are: ammonium nitrogen, heavy metals. They do not go far beyond the standard. However, according to the values obtained through the relevant formula, the use of such untreated water in household activities is not recommended.

Also, the overall acidity, alkalinity, and mineralization range within the expected conditions.

Our recommendation to the population is: not to drink water (so-called rural water) entering the yards directly from the river without filtration.

The inhabitants survey showed that the population still needs a lot of educational work to make each of them environmentally educated.

**RESUMO**

Todas as linhas e máquinas transportadoras devem funcionar sem problemas durante a produção para lançamento dos produtos oportuno. Existem peças e componentes, cuja falha leva à falha de toda a transportadora. É o tempo de entrega e as perdas financeiras devido ao tempo de inatividade do equipamento que tornam relevante o problema de reprodução rápida da peça para substituir a original. Neste artigo, consideramos o processo de criação de uma peça de teste usando a tecnologia de fusão seletiva a laser (SLS). Nesse caso, a eficiência econômica da produção de produtos depende diretamente da solução eficaz e correta dos problemas de preparação tecnológica da produção aditiva. A amostra impressa foi testada em contato direto com o meio aquoso por 500 horas. Os testes de fadiga foram realizados utilizando 40% de pó primário e 60% de pó secundário. Para a avaliação quantitativa das propriedades do material com uma dada geometria, foi realizada uma série de testes de ruptura dos produtos da peça. Para identificar a melhor proporção de resistência, elasticidade e custo de fabricação, nos testes foram apresentadas as amostras com diferentes porcentagens de pó. Observou-se que o custo de fabricação de peças, ferramentas e acessórios de reposição usando a impressão 3D depende de muitos fatores. Os principais fatores de influência foram a geometria dos produtos, que determina seu volume, bem como a densidade de sua disposição na câmara. A experiência acumulada e a análise dos critérios nos permitiram oferecer várias opções de layout que podem levar ao máximo efeito econômico.

**ABSTRACT**

All conveyor lines and machines should work smoothly in order to ensure a well-timed production during production. There are parts and nodes, the failure of which leads to the failure of the entire conveyor. It is the delivery time and financial losses due to equipment downtime that make the problem of quick reproduction of the relevant part to replace the original one. In this work, the process of creating a test piece using selective laser fusion (SLS) technology was considered. In this case, the economic efficiency of the fabrication of products depends directly on the effective and correct solution to the problems of technological preparation of additive production. The printed model was tested in direct contact with water for 500 hours. Fatigue tests were performed using 40% primary and 60% secondary powder ratios. To quantify the properties of the material for given geometry, a series of tensile testing of products was carried out. To identify the best ratio of strength, elasticity, and manufacturing cost for testing, samples were offered with different percentages of powder. It was noted that the cost of manufacturing spare parts, tools, and accessories (SPA) using 3D printing depends on many

factors. The product geometry determines their volume, and the density of their arrangement in the chamber was recognized as a crucial impact factor. The accumulated experience and analysis of the criteria allowed us to offer several layout options that can lead to a maximum economic effect.

**Keywords:** *reverse engineering, fixator, 3D scanning, automatic layout.*

## АННОТАЦИЯ

Все конвейерные линии и станки должны работать бесперебойно во время производства для обеспечения своевременного выпуска продукции. Существуют детали и узлы, поломка которых приводит к выходу из строя всего конвейера. Именно сроки поставки и финансовые потери из-за простоя оборудования делают актуальным вопрос быстрого воспроизводства детали для замены оригинальной. В данной работе рассмотрен процесс создания тестовой заготовки по технологии выборочного лазерного сплавления (SLS). В данном случае экономическая эффективность производства изделий зависит напрямую от эффективного и корректного решения задач технологической подготовки аддитивного производства. Напечатанный образец тестировался в непосредственном контакте с водной средой в течении 500 часов. Испытания на усталость проводились с использованием 40% первичного и 60% вторичного соотношения порошка. Для количественной оценки свойств материала при заданной геометрии был проведен ряд испытаний изделий-заготовок на разрыв. Для выявления наилучшего соотношения по прочности, эластичности и стоимости изготовления на испытания были представлены образцы с разным процентным соотношением порошка. Было отмечено, что стоимость изготовления запасных частей, инструментов и принадлежностей (ЗИП) с помощью 3D-печати зависит от множества факторов. Ключевыми факторами влияния были признаны геометрия изделий, определяющая их объем, а также плотность компоновки их в камере. Нарботанный опыт и анализ критериев позволил предложить несколько вариантов компоновок, которые способны привести к максимальному экономическому эффекту.

**Ключевые слова:** *реверс-инжиниринг, фиксатор, 3D сканирование, автоматическая компоновка.*

## 1. INTRODUCTION

Many works have been devoted to the development and modeling of complex composite structures from anisotropic materials (Babaytsev *et al.*, 2017; Koshoridze *et al.*, 2017; Babaytsev, and Zotov, 2019; Babaytsev *et al.*, 2019). Mainly, one of the options for obtaining such structures is 3D printing (Nazarov, 2011; Boytsov *et al.*, 2011; Atzeni and Salmi, 2012; Mellor *et al.*, 2014; Bepalov *et al.*, 2019; Kuzovkin and Suvorov, 2014; Piller *et al.*, 2015; Anamova *et al.*, 2016; Ripetskiy *et al.*, 2016; Babaytsev *et al.*, 2017; Rabinskiy *et al.*, 2017; Ripetskiy *et al.*, 2018; Kuprikov *et al.*, 2019). The area of use of such products is too vast. For example, to ensure the timely manufacture of products, the operation of all conveyor lines and machines should run smoothly. Failure per under such conditions may not be dangerous, provided that spare parts, tools, and accessories are available (SPA) (Bhutani *et al.*, 2017; Böckin and Tillman, 2019; Kolotyryn *et al.*, 2019; Westerweel *et al.*, 2019; Pellens *et al.*, 2020). However, there are parts and components, the failure of which leads to failure of the entire conveyor (Boboc *et al.*, 2019; Zhang, 2019). In the conditions of reality of Russian industrial enterprises to supply spare parts (including ones

of foreign manufacture) is difficult and to predict when the break occurs is not always possible. Therefore, with a slight breakdown, the entire production line can stop (Zhang and Chang, 2011; Yumashev *et al.*, 2019; Bulavin *et al.*, 2018).

Using the example of individual elements of the conveyor, it can be considered the reverse engineering cycle, timing of reproduction, and economic effect compared with the original part. The fixator (Figure 1) is a part of the conveyor for moving workpieces. This part is a knowingly weak link of the machine and most frequently fails. At the same time, it is impossible to predict how long the original part will last. The reason for this includes several factors:

1. The part works in constant contact with workpieces, due to which there is wear at the points of contact.
2. The occurrence of a defective workpiece can ruin the part and damage it.
3. Failure of automatic workpiece feed mode and also disables the part.
4. This part is knowingly weak link to prevent a chain reaction of breakdowns on the conveyor – when the fixator fails, and the workpieces are not transferred further along the

line.

The cost of the original part “fixator” is over 800 units, and the delivery time takes about 1.5 weeks. It is delivery times and financial losses due to equipment downtime that make the issue of quick reproduction of parts relevant for replacing the original ones (Song and Zhang, 2016; Alekseev *et al.*, 2019; Sobczak-Kupiec *et al.*, 2012; Sobczak-Kupiec *et al.*, 2018). The cycle, including 3D scanning, 3D printing using SLS technology, processing, and delivery, takes from 2 to 4 days (Georgios Tsoutsos *et al.*, 2017; Kim, 2019; Tashi *et al.*, 2019; Skvortsov *et al.*, 2012). Depending on the volume and arrangement of the chamber parts and the proportions of the powder used, the benefit can be 50 to 60%. Going through reverse engineering, revision, and printing cycle is becoming preferable for enterprises than waiting for the original spare part (Revilla-León *et al.*, 2018; Sevryukova *et al.*, 2012; Revilla-León *et al.*, 2019; Koltunov *et al.*, 2018; Revilla-León *et al.*, 2020).

## 2. MATERIALS AND METHODS

In this article, the process of creating a test piece using selective laser fusion (SLS) technology was considered. In this case, the economic efficiency of manufacturing the products depends directly on the effective and correct solution to the problems of technological preparation of additive production. The most powerful influence on the result is exerted by the task of the technical layout of products in the construction chamber — the search for a layout solution.

To obtain high-quality electronic models for real products, three-dimensional scanning equipment was used – the FARO Arm EDGE coordinate measurement machine (CMM) and the Kreon ZEPHYR KZ25 laser nozzle. The working area of the CMM is 1800 mm, which is sufficient to obtain electronic models of any spare parts and elements of the conveyor belt line. The Kreon ZEPHYR KZ25 non-contact laser scanner has the technical characteristics presented in Table 1. The use of such mobile CMMs and easily removable nozzles (non-contact laser scanners) calls for their use in close proximity to the production site, which helps to quickly obtain the desired product. The electronic models obtained from the measurement results were put into production.

The arrangement of products is made according to some limiting criteria (Ripetskiy *et al.*, 2016). The experience obtained during the work

with the installation of selective laser sintering EOSINT P 395, allowed to highlight the most important of them:

- the indent from walls of the build chamber to the nearest part should be at least 15 mm;
- the distance between any two points on the surface of two different parts should not exceed 6 mm;
- in order to maintain the homogeneous structure and, as a result, the same strength characteristics, all products, in the beginning, should be oriented identically with respect to the growing direction (vectors perpendicular to the layers of future products should be collinear).

The key parameters that affect cost of the product at the stage of assembly are:

- layout height;
- layout density, determined from the volume of parts placed at the beginning of a given height;
- time spent on choosing the optimal layout solution;

It is important to note that an attempt to increase density of layout and neglect the criteria reduces the reliability of the launch and can lead to spoilage of products, and even to failure of the installation of SLS-printing (Willmann, 2019). Figure 2 displays a horizontal arrangement of the components in manual mode, this layout has height of construction 32 mm and can accommodate 18 parts. The horizontal arrangement allows us to use less material along the height of chamber, but the percentage of unused material is quite high. To calculate the cost of printing, it is should be considered the following indicators:

- assembly height – 26.63 mm;
- placement density – 14.22%;
- use of platform volume – 0.61%;
- volume of parts – 437.834 cm<sup>3</sup>;
- number of parts – 18 pcs.

To achieve the optimal value, it is necessary to increase the number of parts, while reducing the density of placement, taking into account the layout criteria listed above. Subject to the above parameters, taking into account the manual arrangement of parts in chamber, the probability of operator error is high, while the time cost is significantly increased. The best solution

would be to use automatic layout. Figure 3 illustrates realization of automatic layout of fixators in vertical arrangement. In a vertical arrangement, more material is used along height of the chamber, while the number of parts has increased by more than 3 times.

Key indicators for layout variant No. 2 will be as follows:

- assembly height – 90.05 mm;
- density of placement – 16.41%;
- use of platform volume – 2.31%;
- volume of parts – 1605. 389 cm<sup>3</sup>;
- number of parts – 66 pcs.

Another important technological limitation is the requirements of SLS-print to the part geometry and resolution of EOSINT P 395. One example is the impossibility of accurately producing functional holes whose axes are perpendicular to the growing direction. Thus, for example, the product fixing the conveyor belt (Figure 4) has a simple geometry in terms of topology, but it takes up quite a lot of space in the construction chamber when placed taking into account the above technological limitations.

Subject to all technological requirements, the density remains small, and the number of parts does not exceed 23 pieces. Figure 5 shows a possible dense arrangement for the parts.

Key indicators for layout of variant No. 3 will be as follows:

- assembly height – 41.27 mm;
- placement density – 10.74%;
- use of platform volume – 0.71%;
- volume of parts – 512.401 cm<sup>3</sup>;
- number of parts – 23 pcs.

Further analysis will demonstrate that this arrangement will not be cost-effective for the introduction of printed fixative products as spare parts for conveyor belts.

The products were made of PA2200 polyamide powder as the most affordable for the selected technology (SLS), as well as having excellent strength and chemical resistance specifications. Technical specifications of this powder are presented in Table 2.

### 3. RESULTS AND DISCUSSION:

SLS technology allows using unprocessed powder material repeatedly. The percentage of

primary and secondary material affects both product properties and pricing. Thus, for example, the cost of a holder when printing exclusively on secondary powder is 100 units. This increases the flexibility of the product, which affects the operation quality. In order to find the optimal proportion in terms of cost in this case, it is necessary to make products with different proportions of the primary and secondary powder in various operating modes. According to the results, changes to the material's geometry (e.g. increasing the wall thickness with a ratio of "0/100") or increasing the amount of primary material to the detriment of the product's cost are needed.

Since the printed part has a porous structure, it is necessary to take into account the hygroscopicity of the product and its effect on operational characteristics. Figure 6 demonstrates the change in mass compared to the original part before and after testing. The weight of the printed holder before the test was 23.23 g. The printed sample was tested in direct contact with the aqueous medium for 500 hours, while the weight increased to 24.08 g. for sample No. 1 and to 24.31 gr. for sample No. 2. The clearance between the clamps has increased from 0 to 1 mm. Fatigue tests were performed using 40% primary and 60% secondary powder ratios. The functional characteristics of the holder remained in the normal range (Mustafin, 2006; Mustafin and Volkov, 1984).

At the moment, the samples with a different material ratio undergo strength and fatigue tests (Table 3). To quantify the properties of the material for the given geometry, a series of tensile testing of blanks were performed. To identify the best ratio of strength, elasticity, and manufacturing cost, samples with different percentages of powder were offered for testing. So, samples 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7 have a ratio of 40 % of the primary powder and 60% of the secondary, while samples 1.6 and 1.7 were already tested under production conditions for 2.5 months of continuous operation (Mellor *et al.*, 2014). Samples 1.8 and 1.9 were made entirely of secondary powder, and in the graphs below, it can be seen that these samples are the most elastic. Tensile tests were performed at a speed of 25 mm/min. Figure 7 presents graphs demonstrating the maximum load of the test samples.

The graph shows that the samples, printed with the use of 3D printing, can stand high maximal loads. Products 9 and 10 printed with a 100% ratio of secondary powder have greater elasticity and did not collapse during testing. Static tests were

also carried out at the same time, the task of which was to determine the boundary conditions, after which the sample would lose its elasticity and cease to take its original shape. Table 4 shows the result of static tests of the holding part for 3 months. The highlighted test holder is marked by red, the blue stands for the original holder (Figure 8) (Anamova *et al.*, 2016; Umbetov *et al.*, 2016a; Umbetov *et al.*, 2016b; Rabinskiy *et al.*, 2017). Comparison of the geometries of the original and used holders showed an increase in the gap between the arcs by 5 mm; in this state, the holder is still able to fulfill its main function of holding the workpieces, but such a part must be replaced (Rabinskiy *et al.*, 2017). Problems prototyping are regarded in (Nazarov, 2011; Kalinsky *et al.*, 2019; Boytsov *et al.*, 2011; Atzeni and Salmi, 2012; Kuzovkin and Suvorov, 2014; Piller *et al.*, 2015).

#### 4. CONCLUSIONS:

This work mentions that the cost of manufacturing spare parts using 3D printing depends on many factors. The geometry of the products, which determines their volume, as well as density of their arrangement in the chamber, were recognized as key factors of influence. The same factors become criteria for the economic efficiency of using SLS technology to solve applied production problems.

Several technological parameters and criteria were analyzed that limit the technical engineer in creating effective layouts. The accumulated experience and analysis of the criteria allowed us to suggest several layout options that can lead to a maximum economic effect. Another critical factor is the improvement in the time of delivery of the finished product to the production line. Analysis of specific production line (Nizhnelomovsky enterprise of the United Penza Plant) demonstrated that timely production of spare parts by 3D printing could reduce delivery time by an average of 2 days.

Therefore, the use of SLS printing for the production of individual elements of the conveyor line can reduce delivery times by an average of 2 times, and for individual products - by 2.5-3 times. The cost of a single product decreases by an average of 37.5 %, and for individual products, it is 1/3 of the cost of the original spare part. This effect was proved on example of specific products and can partially be transferred to other applications for quickly creating spare parts in production conditions. The issue of expanded use of SLS printing, as well as other rapid prototyping tools, is part of the task of further research on the

subject.

In addition to the above-mentioned positive effects of the introduction of 3D printing, it is necessary to take into account the series and uniqueness of products, and it is important to understand at which stage it can be switched to other production technologies. Further tasks in this direction are to determine the criteria and requirements for the geometry of products, as well as to create a mathematical apparatus that could let us confidently determine the production technology of specific products to achieve the maximum economic effect. Presently, work in this direction is also proceeding.

#### 5. ACKNOWLEDGMENTS:

The work was carried out with the financial support of the state project of the Ministry of Education and Science on the topic "Theoretical and experimental research in production and processing of advanced metal and composite materials based on aluminum and titanium alloys" FSFF-2020-0017.

## RESUMO

Embora vários compostos sintéticos tenham uma boa ação como anticorrosivo, eles não são baratos e são tóxicos para o meio ambiente e para os seres humanos. No entanto, no aço carbono (aço-C) existe uma preocupação vital que é o sério problema de corrosão devido à exposição a ambientes de acidez agressiva, ou seja, descalcificação, soluções de acidez de poços de petróleo e decapagem. Portanto, este estudo teve como objetivo avaliar o efeito de inibição do extrato de cebola selvagem (WO) como um inibidor ecológico no comportamento da corrosão do aço-C em HCl 0,5 M através da abordagem convencional de perda de peso. Várias concentrações (0%, 0,5%, 1%, 1,5%, 2% e 2,5%) de inibidor em vários períodos de imersão (2, 4 e 8 h) e em diferentes temperaturas (25 °C, 35 °C e 45 °C) foram investigados quanto à inibição da corrosão do aço-C em meios corrosivos. Na presença e ausência do inibidor, a taxa de corrosão (CR) foi investigada como afetada pela temperatura. A concentração do inibidor e a temperatura controlaram a eficiência da inibição (%E) do inibidor. Na existência de extrato de cebola selvagem, a eficiência ideal de inibição para o aço-C foi de 98,95%, 88,99% e 86,79% nas concentrações de inibidor de 2,5% nas temperaturas anteriores, respectivamente. Observou-se que a adsorção era espontânea e física, conforme comprovado pelo valor de adsorção da energia livre de  $\Delta G^{\circ}_{ads}$  (13,5 kJ/mol), além de também ser isotérmica de adsorção de Langmuir. Os dados de cobertura da superfície  $\theta$  e da densidade de corrente de corrosão  $I_{corr}$  confirmaram o resultado anterior em que a inibição ocorre devido à adsorção da natureza física dos componentes do aditivo na superfície do aço-C.

## ABSTRACT

Even though various synthetic compounds have a well action as anticorrosive, they are not cheap and are toxic to both environment and humans. Nevertheless, in C-steel, there is a vital concern, which is serious corrosion issues happen through exposure to environments of aggressive acidity i.e., descaling, oil well solutions of acidity, and pickling. Hence, this study aimed to evaluate the inhibition effect of wild onion (WO) extract as an eco-friendly inhibitor on the behavior of corrosion for C-steel in 0.5 M HCl through the conventional weight loss approach. Various concentrations (0%, 0.5%, 1%, 1.5%, 2%, and 2.5%) of inhibitor in various times of immersion (2, 4, and 8 h) and at different temperatures (25°C, 35°C and 45°C) were investigated for their C-steel corrosion inhibition in corrosive media. In the presence and absence of the inhibitor, the corrosion rate (CR) was investigated as affected by temperature. The concentration of the inhibitor and temperature-controlled the inhibition efficiency %E of the inhibitor. At the existence of wild onion extract, the ideal efficiency of inhibition for C-steel was 98.95%, 88.99%, and 86.79% at 2.5% inhibitor concentrations at the preceding temperatures, respectively. It was noticed that adsorption was spontaneous and physical as proved through adsorption value of free energy  $\Delta G^{\circ}_{ads}$  (-13.5 kJ/mol) and also fitted Langmuir adsorption isotherm. The surface coverage  $\theta$  and corrosion current density  $I_{corr}$  data confirmed the previous result where inhibition is due to the adsorption of physical nature for the components of the additive on the C-steel surface.

**Keywords:** Wild onion; C-steel; Corrosion inhibition; Inhibition thermodynamic.

## 1. INTRODUCTION:

In various kinds of industrial applications, carbon steel (C-steel) has a significant role due to its availability and low price (El-Lateef *et al.*, 2016). Nevertheless, in C-steel, there is a vital concern, which is serious corrosion issue happens through exposure to environments of aggressive acidity, i.e., descaling, oil well solutions of acidity, and pickling (Banerjee *et al.*, 2014). The temperature effect is of theoretical and practical significance on chemical reactions. As of most reactions, with elevated temperature, the corrosion rate of steel and Fe increases, particularly at medium where H evolution along with corrosion is accompanied, i.e., through steel corrosion in acidic solution (Hamdy and El-Gendy, 2013). As one of the most vital and significant strategies, inhibitors of corrosion have been practiced for C-steel anti-corrosion, especially in acidic solution, to prevent metal dissolution and acid consumption (Khadom *et al.*, 2009). Although various synthetic compounds have a great action as anticorrosive, they are not cheap and are toxic to both environment and humans (Garai *et al.*, 2012). Toxicity might show manifestation either through compound synthesis or through applications, which makes researchers concentrate on using substances occurring naturally to obtain inhibitors that are non-hazardous and cheap (Ahmed and Quraishi, 2013). The compound to behave as an inhibitor for corrosion, requirements should be available; as far as the behavior of chemical and its structure, an inorganic compound readily oxidizes the metal by forming on the surface a passive layer. Also, an organic molecule should possess inhibitor characters to behave as a corrosion inhibitor; the double bonds, molecules with a large structure and an active group or center, etc. These characters render these molecules cover a considerable area surface of the metal (film) with firm attachment. Plants considered as inhibitor source of many ones, which is clean and cheap (Fouda *et al.*, 2014). Plants extracts (i.e., seeds, leaves, flowers, and fruits) possess various active compounds with the ability of corrosion inhibition in aggressive media had been considered in recent studies (Khadom *et al.*, 2018; Mobin *et al.*, 2018; Haldhar *et al.*, 2018; Banu *et al.*, 2018). In this regard, different

investigators are concentrating on the growth of friendly environmentally inhibitors of corrosion, i.e., natural products, *Spirulina platensis* (Gopiraman *et al.*, 2012), *Brugmansia suaveolens* (Kamal, *et al.*, 2012), green eucalyptus leaves (Dehghani *et al.*, 2016), *Acalypha torta* (Krishnegowda *et al.*, 2013), *Luffa aegyptiaca* (Jyothi and Ravichandran, 2014), watermelon rind (Odewunmi *et al.*, 2015), *Ligularia fischeri* (Prabakaran *et al.*, 2018), *Lansea coromandelica* (Muthukrishnan *et al.*, 2017), *Tilia cordata* (Fouda *et al.*, 2017), sweet melon peels (Saeed *et al.*, 2019), *Griffonia simplicifolia* (Ituen *et al.*, 2017), *Dillenia Pentagyna* fruits (ManjunathHegde *et al.*, 2019), *Pongamia pinnata* (HouariaDerfouf *et al.*, 2019). The existence of organic plant compounds, i.e., carbohydrates, flavonoids, alkaloids, saponins, and phenols, make them well source inhibitors of corrosion. These phytochemicals possess various functional groups like hydroxyl, carbonyl, and amino (Sakunthala *et al.*, 2019). Thus, these plants behave as well as inhibitor sources of corrosion that should not be neglected.

Wild onion (WO) plant (*Urginea maritima*), a medicinal plant from the area of Mediterranean, belongs to the family Liliaceae. WO grows naturally in the wild, explicitly cultivated (Deb and Dasgupta, 1987). The parts of medicinal importance are the bulbs which harvested, transversely sliced, and grounded for being ready to used (Gentry *et al.*, 1987). Genus of *Urginea* is traditionally used in medicine because of its antiepileptic, cardiotoxic, diuretic, anti-asthmatic, and dermatological characteristics (El-Seedi *et al.*, 2013).

The purpose of this study was to investigate the corrosion inhibition ability of WO extract for C-steel in a 0.5 M HCl solution using weight loss measurements.

## 2. MATERIALS AND METHODS:

### 2.1. Preparation of specimens

The coupons of C-steel (5 x 2.6 x 0.3 cm) with the composition of % V, 0.21 wt., 0.34 wt. % C, 0.51 wt. % P, , 0.035 wt. % Cr, 0.44 wt. % Mn, 0.017 wt. % Al, 0.054 wt. % Mo and Fe (balance), were applied in this paper (Figure 1). The coupon surface polished by emery paper of grit from 400 to 600 grades prepares sequentially to the polished surface. After polishing, the coupons

were washed with tap water then by distilled water and dried with clean tissue with hot air and finally in desiccators to get coupons moisture-free before storage and use.

**Figure 1.** Coupons of C-steel.

## 2.2. Wild onion (WO) extraction

WO plant was collected from lawns of Duhok governorate, Kurdistan Region of Iraq (Figure 2). The bulbs were washed and cut into small pieces and then dried under shadow at ambient temperature then ground into a fine powder. For the extraction procedure, 10 g of WO powder was weighed and mixed with 100 ml of (90% methanol) in a conical flask. The mixture was extracted during stirring for 24h at room temperature. The resultant mixture was filtered carefully, and the methanol evaporated by drying in an oven at 45°C for 2h. A yellow-brown sticky residue of dried WO extract was obtained. The dried extract was stored in a refrigerator for further use.

**Figure 2.** Wild onion plant (*Urginea maritima*).

## 2.3. Preparation of corrosive solution

The electrolyte corrosive was 0.5 M HCl solution that was prepared from HCl (37%) analytical grade and distilled water. The inhibited solutions were prepared by adding WO extract to 0.5 M HCl prepared freshly at different concentrations (0.5%,

1%, 1.5%, 2%, and 2.5%).

## 2.4. Loss of weight measurements

Through measurement of weight losing, each coupon specimen was weighted carefully and then immersed in the 0.5 M HCl solution with various dried extract concentrations of WO (0%, 0.5%, 1%, 1.5%, 2%, and 2.5%) at (25, 35 and 45°C), respectively. After (2, 4 and 8hr) immersion in the solution, the specimens were taken out and washed in tap water for removal all products of corrosion on the surface of the metal, washed another time with distilled water (DW), dried by clean tissue and hot air, and then weighed after they have been kept in desiccators for 3h. The same procedure was repeated for each temperature.

From the weight loss data, the CR was calculated by applying Eq. (1) (Tredder, 1984).

$$CR \text{ (mpy)} = \frac{534 W}{D A T} \quad (1)$$

Where:

CR (mpy): is the corrosion rate in mills per year.

W: is weight loss (mg).

D: density (g/cm<sup>3</sup>).

A: area of the C-steel coupon (in<sup>2</sup>).

T: time exposure (h).

By applying Eq. (2), the efficiency of inhibition (%E) was calculated (Danielson, 1982).

$$\%E = \frac{CR_o - CR_i}{CR_o} \times 100 \quad (2)$$

Where:

CR<sub>o</sub> and CR<sub>i</sub>: are the CRs in the presence and absence of various inhibitor concentrations, respectively.

By applying Eq. (3), the coverage of the surface (θ) was calculated (Damaskin, 1971).

$$\theta = 1 - \frac{CR_i}{CR_o} \quad (3)$$

### 3. RESULTS AND DISCUSSION:

#### 3.1 Measurements of weight-losing and temperature effect

CR variation, inhibition efficiency %E and coverage of surface  $\theta$  were evaluated through measurement of C-steel weight losing of in the media of corrosives with different concentrations of (WO) extract, and different temperatures are shown in the Tables 1, 2 and 3 and Figures 3, 4, 5, 6, 7 and 8. Results proved that the CR was declined as the inhibitor concentration elevated; i.e., in the solution of blank acidic, after 2h, the CR of C-steel was 41.45 (mpy), which decreased to 9.56 (mpy) with the addition of 0.5% of (WO) extract at 25°C. In the presence of 2% inhibitor, CR of C-steel was approximately 10 times lower compared to blank solution where the foregoing trials were proved. As the temperature increased, CR increased significantly from 41.45 (mpy) to 109.63 (mpy) and then to 185.7 (mpy) with an increase in temperature at the above, respectively, in blank acidic solution. Nevertheless, the effectiveness at each temperature for inhibitor extract was assumed from the significant CR decrease.

Inhibition efficiency (%E) values and surface coverage  $\theta$  elevated by elevating the concentration of inhibitor because of the inhibitor adsorption on the C-steel surface which occurred and formed a layer of protective coverage on surface of the C-steel (Moore, 1994).

Maximum inhibition efficiency %E of about 98.95% was reached in 2.5% of inhibitor concentration at 25°C and after 8hr. By increasing temperature, the efficiency of inhibition %E declined; i.e. efficiency inhibition %E was decreased from 98.95% to 88.99% and then to 86.79% when temperature elevated to 35°C and to 45°C, respectively from 25°C at 2.5% of the inhibitor concentration. The CR in current density units  $I_{corr}$  can be related to the weight loss by Eq. (4) (Moore, 1994)

$$I_{corr}(\text{mA}/\text{cm}^2) = \frac{2 \cdot 1000 \cdot W \cdot F}{A_w \cdot T \cdot A} \quad (4)$$

Where:

$I_{corr}$  = corrosion current density (mA/Cm<sup>2</sup>).

F = Faraday constant, 96500 coulombs.

$A_w$  = Atomic weight of Fe, 55.9.

T = Exposure time (sec.).

A = Specimen external surface area (Cm<sup>2</sup>).

W = corrosion weight losing (mg.).

Table 4 shows the variation of the corrosion current density  $I_{corr}$  values for the C-steel in HCl solution of 0.5 M with different temperatures, immersion times, and inhibitor concentrations. By concentration elevating, the density of current corrosion  $I_{corr}$  decreased, and the efficiency of WO extract inhibition increased. This might occur because of the adsorption of various inhibitor compounds on the surface of C-steel. Thus, WO extract addition decreased both the partial reaction rate through declining the dissolution of anodic and lowering down the H reaction evolution and blocks C-steel attack in the acid media (Solmaz *et al.*, 2008). Table 4 shows that the values of  $I_{corr}$  were elevated with elevating temperature from 25°C to 45°C; this is due to the temperature increase, which led to the desorption of protective layer on the surface of C-steel increase (Ramesh, 2003; Shaker, 1986; Adam, 1986).

#### 3.2. Immersion time effect

Determination of the inhibitor stability adsorption on the C-steel surface by losing weight measurement was performed with different inhibitor concentrations at different immersion times (2, 4, and 8h) and various temperatures (25°C, 35°C and 45°C). Figures 9, 10, and 11 show that as the immersion time increased, inhibition efficiency %E increased at 25°C. In comparison, at 35°C and 45°C a decrease was found in the inhibitor efficiency %E as the immersion time increased. The recent results may be due to the desorption of inhibitor on the surface of C-steel when the temperature rose. Maximum inhibition efficiency %E was lower at 45°C than at 35°C and 25°C. Based on the available literature, when temperature increased, it caused a decrease in the efficiency of inhibition. This might be attributed to the desorption of inhibitor constituents from the surface of the metal. In this situation, the adsorption is basically because of the interaction of electrostatic that declined at high temperatures. This proved that the

process of adsorption is a physisorption type (Sakunthala, 2013; Karthik and Sundaravadivelu, 2017).

### 3.3. Adsorption isotherm

The isotherms of adsorption are mathematical expressions that provide data about the reciprocal effect of the metal surface and adsorbing species at a fixed temperature. Generally, in acid corrosion, it is presumed that act of inhibitors by an adsorption process on the surface of the metal. The adsorption behavior is dependent on the amount of coverage surface  $\theta$ , were obtained by weight loss studies. An isotherm of adsorption provides the relation between the interface coverage with the species that adsorbed and the species concentration in solution. To examine the isotherm of adsorption, a graphic relation between the concentration inhibitor  $C_{inh}$  and  $C_{inh}/\theta$  at various temperatures was graphed and showed in Figure 12. In this figure, straight lines can be seen, and the correlation values of coefficient  $R^2$  were nearly equal to one pointing this system followed Langmuir isotherm of adsorption Eq. (5) at different temperatures. The above result indicated as well that inhibitor of mono-layer should be adsorbed to the surface of C-steel without any interaction among the molecules that adsorbed (Hamdy and El-Gendy, 2013; Faustin *et al.*, 2015).

$$\frac{C_{inh}}{\theta} = \frac{1}{K_{ads}} + C_{inh} \quad (5)$$

Where:

$C_{inh}$ : the concentration of inhibitor

$\theta$ : average degree of coverage on the surface metal

$K_{ads}$ : adsorption process constant equilibrium.

The inhibitor's equilibrium adsorption constants ( $K_{ads}$ ) were calculated by the linear equations intercept  $C_{inh}/\theta$  versus  $C_{inh}$  [8]. To compute the free energy standard of adsorption, value of  $K_{ads}$  was used ( $\Delta G^\circ_{ads}$ ) value based on the following (Bentiss *et al.*, 2009):

$$\Delta G^\circ_{ads} = -2.303 RT \log (55.5 K_{ads}) \quad (6)$$

The value of 55.5 was the

concentration of water in solution expressed in mol/L. The adsorption constants  $K_{ads}$  and free energy of standard adsorption  $\Delta G^\circ_{ads}$  values at different temperatures were grouped in Table (5).

Generally, the values of  $\Delta G^\circ_{ads}$  up to  $-20$  kJ/mol are accepted, adsorption kinds were considered as physisorption; acts of inhibition were attributed to the interaction of electrostatic between charged metal and the charged molecules, whereas values smaller than  $-40$  kJ/mol or around were observed as chemisorption. This is because of sharing the charge or a transfer to the surface of metal from the molecules of the inhibitor to form covalent bonding (Yurt *et al.*, 2005).

At the present investigation, the negative sign of  $\Delta G^\circ_{ads}$  proved that the inhibitor adsorption was spontaneous. The computed adsorption values of free energy  $\Delta G^\circ_{ads}$  at different temperatures were around of  $-13.5$  kJ/mol that assists the physical mechanism of adsorption (Adejoro *et al.*, 2015; Ali *et al.*, 2017).

### 4. CONCLUSIONS:

The CR declined as the concentration of inhibitor elevated and the efficiency of inhibition %E raised with elevating the inhibitor of concentration but decreased with temperature raising. The decline in the efficiency of inhibition with elevating temperature was suggestive of mechanism for physical adsorption (physisorption). It might be due to solubility increase in the products of protective film precipitated on the C-steel surface, which may otherwise inhibit the process of corrosion. The overall results of the current work revealed that the eco-friendly wild onion extracts is a promising corrosion behavior of C-steel in acidic media.

**RESUMO**

A doença periodontal na população adulta é um dos problemas mais urgentes da odontologia em todo o mundo. Graças à introdução de modernas tecnologias na prática, foi possível identificar os principais mecanismos de desenvolvimento desta doença nos níveis molecular e genético. A interação de patógenos periodontais com fatores imunes da proteção antimicrobiana do corpo é a base da inflamação do tecido periodontal e leva ainda à destruição do osso alveolar. As células epiteliais da mucosa gengival desempenham um papel crucial contra bactérias patogênicas periodontais. Os fatores de imunidade inata desempenham um papel não apenas na proteção antimicrobiana, mas também apóiam as condições necessárias para a cura e regeneração dos tecidos periodontais. Portanto, várias abordagens terapêuticas que afetam os fatores de imunidade inata são consideradas efetivas e promissoras. O exame clínico e a determinação dos fatores de imunidade inata foram realizados em 115 pacientes. Indivíduos saudáveis compunham um grupo de 30 pessoas. Pacientes com periodontite crônica generalizada com diferentes graus de gravidade eram 85 pessoas. Cada paciente foi submetido à ortopantomografia no ortofantomógrafo Orthophosis XG-DS/Ceph (SIRONA Dental System GmbH, Alemanha) para avaliar o estado do tecido ósseo dos maxilares (o grau de destruição da camada cortical, o grau de reabsorção do interalveolar). Radiografias intraorais direcionadas foram usadas para avaliar o estado do tecido ósseo e a qualidade do tratamento cirúrgico. Os métodos imunológicos de pesquisa foram realizados em várias etapas. Os achados deste artigo afirmam que o uso de imunopeptídeos complexos autólogos no tratamento cirúrgico da periodontite reduz o tempo de obtenção de um efeito terapêutico 2 vezes, resultando no alívio rápido dos sintomas de inflamação e na aceleração dos processos reparativos.

**ABSTRACT**

Periodontal disease in the adult population is one of the most pressing problems of dentistry around the world. Thanks to the introduction of modern technologies in practice, it was possible to identify the main mechanisms of the development of this disease at the molecular and genetic level. The interaction of periodontal pathogens with immune factors of antimicrobial protection of the body is the basis of periodontal tissue inflammation and further leads to the destruction of the alveolar bone. Epithelial cells of the gum mucosa play a crucial role against periodontal pathogenic bacteria. Factors of innate immunity play a role not only in antimicrobial protection, but they also support the conditions necessary for the healing and regeneration of periodontal tissues. Therefore, various therapeutic approaches that affect the factors of innate immunity are considered as effective and promising. Clinical examination and determination of factors of innate immunity were performed in 115 patients. Healthy individuals made up a group of 30 people. Patients with chronic generalized periodontitis with varying degrees of severity were 85 people. Each patient underwent orthopantomography on the orthopantomograph Orthophosis XG DS/Ceph (SIRONA Dental System GmbH, Germany) in order to assess the state of the bone tissue of the jaws (the degree of destruction of the cortical layer, the degree of resorption of the

interalveolar partitions). Targeted intraoral radiographs were used to assess the state of bone tissue and the quality of surgical treatment. Immunological methods of research were carried out in several stages. The findings of this article make the claim that the use of autologous complex immunopeptides in the surgical treatment of periodontitis reduces the time of achieving a therapeutic effect 2 times, resulting in the rapid relief of the symptoms of inflammation and acceleration of reparative processes.

**Keywords:** *immunity, periodontitis, immunopeptides, patchwork, bone tissue.*

## АННОТАЦИЯ

Заболевания пародонта среди взрослого населения представляют одну из актуальных проблем стоматологии во всем мире. Благодаря внедрению в практику современных технологий, удалось выявить основные механизмы развития данного заболевания на молекулярно-генетическом уровне. Взаимодействие пародонтопатогенов с иммунными факторами противомикробной защиты организма лежит в основе воспаления тканей пародонта и в дальнейшем приводит к деструкции альвеолярной кости. Эпителиальные клетки слизистой оболочки десны играют решающую роль в отношении пародонтопатогенных бактерий. Факторы врожденного иммунитета играют роль не только в противомикробной защите, они также поддерживают условия, необходимые для заживления и регенерации тканей пародонта. Поэтому различные лечебные подходы, влияющие на факторы врождённого иммунитета, рассматриваются как эффективные и перспективные. Клиническое обследование и определение факторов врождённого иммунитета было проведено у 115 пациентов. Здоровые лица составили группу из 30-и человек. Пациенты с хроническим генерализованным пародонтитом с разной степенью тяжести составили 85 человек. Каждому пациенту проводили ортопантомографию на ортопантомографе Orthophosis XG DS/Ceph (SIRONA Dental System GmbH, Германия) с целью оценки состояния костной ткани челюстей (степень деструкции кортикального слоя, степень резорбции межальвеолярных перегородок). С целью оценки состояния костной ткани и качества хирургического лечения использовали прицельные внутриротовые рентгенограммы. Иммунологические методы исследования проводили в несколько этапов. Результаты исследования данной статьи позволяют сделать утверждение, что применение аутологичного комплекса иммунопептидов при хирургическом лечении пародонтита сокращает сроки достижения лечебного эффекта в 2 раза, что выражается в быстром снятии симптомов воспаления и ускорении репаративных процессов.

**Ключевые слова:** *иммунитет, пародонтит, иммунопептиды, лоскутные операции, костная ткань.*

## 1. INTRODUCTION

Periodontal diseases in the adult population are one of the most pressing problems of dentistry in the world. Thanks to the introduction of modern technologies in practice, it was possible to identify the main mechanisms of development of this disease at the molecular genetic level [Balykin, 2016; Zorina *et al.*, 2016, 2017; Mamedov *et al.*, 2019; Utyuzh *et al.*, 2019].

Epithelial cells of the gingival mucosa together with humoral and cellular factors of saliva and gingival fluid from the first line of protection of the body from infection and play a crucial role against periodontal pathogenic bacteria [Platonova *et al.*, 2018; Sevbitov *et al.*, 2018; Mitin *et al.*, 2019; Sevbitov *et al.*, 2020; Timoshin *et al.*, 2018, 2019]. The epithelium of the gingival mucosa expresses Toll-like receptors (TLR) that recognize the lipopolysaccharides of anaerobic bacteria and contribute to the production of proinflammatory cytokines, chemokines, and other mediators that regulate inflammation [Sevbitov *et al.*, 2019, 2020;

Bostanci *et al.*, 2012; Kolodkina *et al.*, 2018; Kuznetsova *et al.*, 2018]. Along with cytokines, the epithelium of the gingival mucosa produces antimicrobial peptides  $\beta$ -defensins (hBD), which have a wide range of antimicrobial activity, causing the death of microorganisms due to violation of the integrity of their membranes [Belibasakis *et al.*, 2015; Cochran, 2008; Cortés-Vieyra *et al.*, 2016; Turgaeva *et al.*, 2020].

Factors of innate immunity play a role not only in antimicrobial protection, but they also support the conditions necessary for healing and regeneration of periodontal tissues. Therefore, various therapeutic approaches that affect the factors of innate immunity are considered as effective and promising [Ding *et al.*, 2014; Dommisch *et al.*, 2015; Garlet *et al.*, 2010; Giannobile *et al.*, 2015; Groeger *et al.*, 2015; Voloshina *et al.*, 2018 ].

At the present stage of periodontitis, treatment attempts are being made to restore all periodontal structures simultaneously, and methods of tissue

engineering and directed tissue regeneration are actively implemented [Hans *et al.*, 2011; Katz *et al.*, 1989; Mudda *et al.*, 2011; Sevbitov *et al.*, 2018, 2019, 2020].

One of the ways to stimulate reparative tissue regeneration is the possibility of influencing cell proliferation and differentiation by a composition of cytokines and growth factors synthesized by autologous cells of the immune system [Reddi, 2001; Shuai *et al.*, 2018; Shue *et al.*, 2012; Song *et al.*, 2016; Enina *et al.*, 2019; Ergesheva *et al.*, 2018; Mironov *et al.*, 2020].

The purpose of our study: to evaluate the effectiveness of immunotherapy using an autologous complex of immunopeptides in the surgical treatment of periodontitis.

## 2. MATERIALS AND METHODS

Clinical examination and determination of factors of innate immunity were carried out in 115 patients. Healthy individuals made up a group of 30 people. Patients with chronic generalized periodontitis with varying degrees of severity were 85 people. With a mild degree - 25 patients, with an average - 40 patients, with a severe-20 patients. Patients with moderate periodontitis (40 people) received conservative treatment, and 1 month after it, surgical treatment was performed in the form of flap operations. The monitoring of long-term results after surgical treatment was carried out within 1, 3, and 6 months.

The gender distribution of patients was as follows: 73 women and 42 men. The age of the surveyed was from 35 to 65 years. The median age was 52 years (Table 1).

**Table 1.** Age distribution of patients

| Groups surveyed        | Age of persons examined (years) |       |       |       |
|------------------------|---------------------------------|-------|-------|-------|
|                        | n                               | 35-45 | 46-55 | 56-65 |
| Healthy faces          | 30                              | 12    | 9     | 9     |
| ChP (complex) patients | 85                              | 22    | 40    | 23    |
| Total                  | 115                             | 34    | 49    | 32    |

The group of people surveyed was

dominated by women, and they were 1.7 times more than men (Table 2).

During the examination of patients, General clinical methods were used (survey, examination, determination of clinical indices), x-ray methods, and filling out medical documentation (Appendix 1).

**Table 2.** Gender distribution of patients

| Groups surveyed        | n   | Men | Women |
|------------------------|-----|-----|-------|
| Healthy faces          | 30  | 12  | 18    |
| ChP (complex) patients | 85  | 30  | 55    |
| Total                  | 115 | 42  | 73    |

Each patient underwent orthopantomography using an orthopantomograph Orthophosis XG DS/Ceph (SIRONA Dental System GmbH, Germany) to assess the condition of the jaw bone (the degree of destruction of the cortical layer, the degree of resorption of the interalveolar septa). In order to assess the state of bone tissue and the quality of surgical treatment, targeted intraoral radiographs were used.

Immunological research methods were carried out in several stages (Figure 6). The first stage involved determining factors of innate immunity in healthy individuals (30 patients) and patients with ChP (complex) with varying degrees of severity (85 patients) before treatment.

At the second stage, in patients with moderate ChP (complex) (40 patients), the factors of innate immunity were determined before and after conservative treatment before they underwent surgical treatment.

The third, fourth, and fifth stages included determining factors of innate immunity in patients with moderate ChP (complex) after surgical treatment within 1, 3, and 6 months.

To determine the expression of the TLR4 and hBD-3 gene in the gum epithelium, a scrape was obtained in the area of the attached gum using disposable sterile probes, which placed an Eppendorf test tube for 2-3 seconds with 0.5 ml of saline solution and frozen at a temperature of -20 °C until the time of the study (Figure. 1). Biological material was collected before treatment, after conservative treatment, before flap operations,

and then 1, 3, and 6 months after surgical treatment.

**Figure 1.** Material intake in the area of the gingival margin during periodontitis (a) and placing the biological material in an Eppendorf tube (b)

Of the samples has been isolated RNA using a kit of reagents "Ampli PRIME RIBO-Sorb" To determine the level of expression of the studied genes, cDNA was obtained using a reverse transcription reaction. At the next stage of the study, a real-time polymerase chain reaction (PCR-RV) was performed on the DT-96 device with the resulting reaction OT cDNA. The reaction was performed using "A set of reagents for PCR-RV in the presence of the intercalating dye SYBR Green I".

To determine cytokines, the contents of periodontal pockets (PC) were collected using sterile paper strips made of filter paper, measuring 0.3 by 0.5 mm, for 30 seconds, then placed in an Eppendorf tube with 100 microl of saline solution and frozen at a temperature of -20 °C until the study was completed (Figure. 2).

**Figure 2.** Gingival fluid intake from a pocket for cytokine detection

The study of the cytokine spectrum in the gingival fluid included determining the level of cytokines - interleukin-6 (IL-6) and transforming growth factor - TGF $\beta$ 1. We used commercial sets of TGF $\beta$ 1 "eBioscience" (USA) for setting the solid-

phase enzyme immunoassay (ELISA) according to the recommended methods. This immunological method for determining various compounds in biological fluids is based on the antigen-antibody reaction [Harrington, L. *et al.*, 2005].

Complex treatment consisted of successive stages and included the following measures: pre-treatment stage (thorough professional, hygienic treatment of the oral cavity), conservative treatment (local antibacterial therapy), surgical treatment (conducting flap operations using the Widman-Neumann method). In total, flap operations were performed in 40 patients with moderate ChP (complex) in the area of 165 teeth. Dynamic follow-up was performed 1-3-6 months after surgical treatment.

On the eve of the flap operations, patients were collected 10 ml of venous blood and immediately transported to the laboratory to obtain an autologous complex of immunopeptides (AKI). Then, according to the technology developed at the Department of Immunology, 5-7 ml of AKI containing cytokines and antimicrobial peptides (TNF $\alpha$ , TGF-1,  $\alpha$ -defensin-HNP1-3) were obtained from leukocyte cultures of patients. In parallel, AKI was obtained from white blood cell cultures of 30 healthy donors.

The course of the operation was as follows: under infiltration anesthesia Sol. Ultracaini 2%-5.0 exfoliated the Muco-periosteal flap, removed dental deposits, granulations, polished the bone edge with a drill, de-epithelization of the gingival edge, the wound surface was irrigated with AKI solution from a syringe in an amount of 1.0-1.5 ml.

The bone defect was filled with osteoplastic material, which was also impregnated with AKI, then sutured in each interdental space.

### 3. RESULTS AND DISCUSSION:

In the postoperative period after flap surgery, patients of the main group with the use of AKI on the 1st day showed no pain symptom, and the mucous membrane was pink. On day 2-3, there was no inflammatory reaction (edema, hyperemia), the interdental papillae were in the epithelization stage, and the sutures were preserved. By day 6-7, there was complete epithelization of the mucosa. The gums were tightly attached to the necks of the teeth, had a pink color, and there was a need to remove the sutures, they were removed completely. Without this method of treatment in the comparison group,

all processes of healing and complete epithelization of the mucosa took place on the 9th-10th day. The removal of stitches was on 13-14 days.

**Table 3.** Clinical indicators of the effectiveness of the use of an autologous complex of immunopeptides in the surgical treatment of periodontitis

| Signs  | Without AKI   | Local AKI     |
|--|---------------|---------------|
|  | n=20          | n=20          |
| 1. Disappearance of signs of inflammation (edema, hyperemia) | 7,0±0,3 day.  | 3,0±0,1 day.* |
| 2. Removal of stitches full                                  | 13,0±1,0 day. | 7,0±0,1 day.* |
| 3. Complete tissue repair                                    | 14,0±1,0 day. | 7,0±1,0 day.* |

\* - reliability of differences in indicators compared to the control,  $p < 0,01$ .

For 12 months. after flap operations (period of observation), patients in the main group and in the comparison group were noted: the absence of inflammatory phenomena, the absence of dental pockets, compaction of the gingival margin, and the lack of tooth mobility.

After 12 months. on the x-ray in the area of the operated teeth, the bone density was determined, and the cortical plate was clearly expressed in both groups compared. There were no differences in bone x-rays in these groups (Figure 4,5).

**Figure 4.** Radiograph of patient A. before surgical treatment in the field of teeth 15.16.17. and 45.46.47. and after surgical treatment with AKI in the field of teeth 15.16.17. (a) after 1 year and 45.46.47. after 1.5 years (b)

**Figure 5.** Radiograph of patient L. before surgical treatment without the use of AKI in the field of teeth 25.26.27. and 34.35.36. (a) and 6th (b) after surgical treatment without AKI in the field of teeth 25.26.27. after 1 year and 34.35.36. after 1.5 years

Thus, after surgical treatment with the use of AKI, pain relief was observed more pronounced in terms of time, the disappearance of inflammatory phenomena (edema, hyperemia), and the onset of epithelization of the wound. All these phenomena occurred 2-3 times faster than in the comparison group. Treatment with AKI was easily tolerated by patients. It allowed limiting the treatment of the wound with antiseptics and taking antibiotics after surgical treatment. Suppuration or other complications were not observed in any case.

The advantages of surgical treatment with the use of AKI can be attributed to its harmlessness in respect of the hepatitis b virus and HIV.

X-ray analysis was performed to determine the density of bone tissue in the area of the operated teeth, as well as the clear severity of the cortical plate in both groups compared. There were no differences in bone radiographs in these groups.

#### 4. CONCLUSIONS:

In patients with ChP (complex), the expression of the TLR4 gene in the gum epithelial cells was increased by 12 times compared to healthy individuals. In severe ChP (complex), the TLR4 gene expression level was highest, 5 times higher than in mild and 3 times higher than in average. The expression of the hBD-3 gene in the gum epithelium in patients with ChP (complex) is increased by 5 times compared to healthy individuals. In mild ChP (complex), the expression of the hBD-3 gene in the gum epithelial cells exceeded the indicators in moderate and severe cases by 2 times. The use of an autologous complex of immunopeptides in the surgical treatment of periodontitis reduced the time to achieve the therapeutic effect by 2 times, which was expressed in the rapid removal of symptoms

of inflammation and acceleration of reparative processes.

## 5. ETHICS APPROVAL:

The study conforms to strobe guidelines. all procedures performed in studies involving human participants were in accordance with the ethical standards of the Sechenov University ethics committee and with the 1964 Helsinki declaration and its later amendments. All human subjects' rights have been protected by the Sechenov University ethics committee, and written informed consent was obtained from all subjects who participated in the study.

## 6. ACKNOWLEDGMENTS:

This work was done at Sechenov University with supported by the "Russian Academic Excellence Project 5-100".

**RESUMO**

O estágio contemporâneo da reforma educacional exige muito da formação de professores e do domínio das mais recentes técnicas e tecnologias de ensino. Em todo o mundo, busca-se novos sistemas educacionais mais democráticos, diversificados e eficazes do ponto de vista dos interesses do indivíduo e da sociedade. Isso requer, por um lado, maneiras novas e mais eficientes de organizar o processo educacional na universidade, em particular, revisando a estrutura e o conteúdo da formação metodológica dos estudantes. Por outro lado, o próprio conceito de “atividade pedagógica profissional de um professor” está passando por certas mudanças. Este estudo teve como objetivo identificar com que eficácia o treinamento metodológico de futuros professores de matemática aumentará com base na introdução de técnicas e métodos de ensino inovadores e como a metodologia de ensino de disciplinas matemáticas nas condições de inovação poderá ser aprimorada. Duzentos e treze pessoas participaram do trabalho experimental, incluindo professores de matemática e estudantes em período integral, estudantes de graduação, doutorado e jovens professores da universidade. Os resultados do experimento determinante tornaram-se a base para a revisão dos propósitos da formação metodológica e profissional de futuros professores de matemática e possibilitaram concluir sobre a necessidade de aperfeiçoar o suporte metodológico do sistema para o ensino de disciplinas matemáticas no ensino superior. Por isso, a formação de um professor de matemática deve torná-lo um matemático experiente, como uma pessoa com uma alta cultura pedagógica e geral, que, ensinando, educaria a geração mais jovem no espírito da modernidade. Pode-se supor que o conteúdo dos cursos de uma universidade pedagógica em disciplinas matemáticas deve, por exemplo, em um nível acadêmico moderno, abranger os assuntos que o professor comunica na escola.

**Palavras-chave:** *ensino de disciplinas matemáticas, processo educacional, programação neurolinguística.*

**ABSTRACT**

The contemporary stage of education reform puts high demands on teacher training and on mastering the newest teaching techniques and technologies. All over the globe, there is a search for new education systems that are more democratic, diversified and effective from the standpoint of the interests of the individual and society. This requires, on the one hand, new, more efficient ways of organizing the educational process at the university, in particular, reviewing the structure and content of the methodological training of students. On the other hand, the very concept of “professional pedagogical activity of a teacher” is currently undergoing certain changes. This study aimed to identify how effectively will the methodological training of future mathematics teachers increase based on the introduction of innovative techniques and teaching methods and how the methodology of teaching mathematical disciplines in the conditions of innovation may be improved. Two hundred thirteen people took part in the experimental work, including teachers of mathematics and full-time students, undergraduates, doctoral students, as well as young teachers of the university. The results of the ascertaining experiment became the basis for revising the purposes of the methodological and professional training of future mathematics teachers and made it possible to conclude on the necessity of improvement of the system-methodological support for teaching mathematical disciplines in higher education. Because of this, the training of a mathematics teacher should form them as a knowledgeable mathematician, as a person with a high pedagogical and general culture, who, by

teaching, would educate the younger generation in the spirit of modernity. It can be assumed that the content of courses in a pedagogical university in mathematical disciplines should, for instance, at a modern academic level, cover those matters that the teacher communicates at school.

## АННОТАЦИЯ

Современный этап модернизации образования предъявляет повышенные требования к профессиональной подготовке преподавателей и освоению ими новейших методик и технологий обучения. Во всем мире идет поиск новых систем образования, более демократичных, диверсифицированных и результативных с позиции интересов личности и общества. Это требует, с одной стороны, новых, более эффективных путей организации учебно-воспитательного процесса в вузе, в частности, пересмотра структуры и содержания методической подготовки студентов. С другой стороны, само понятие «профессиональная педагогическая деятельность преподавателя» подвергается в настоящее время определенным изменениям. Цель данного исследования заключается в определении эффективности совершенствования методической подготовки будущих учителей математики при внедрении инновационных техник и методов обучения, а также улучшении методологии преподавания математических дисциплин в условиях инноваций. В экспериментальной работе приняли участие двести тринадцать человек, в том числе учителя математики и студенты дневного отделения, магистранты, докторанты, а также молодые преподаватели университета. Результаты констатирующего эксперимента стали основой для пересмотра целей методической и профессиональной подготовки будущих учителей математики и позволили сделать вывод о необходимости совершенствования системно-методического обеспечения преподавания математических дисциплин в высшей школе. Учитывая это, подготовка должна сформировать учителя математики как грамотного преподавателя, человека с высокой педагогической и общей культурой, который способен воспитать молодое поколение в духе современности. Содержание курсов в педагогическом университете по математическим дисциплинам на современном академическом уровне должно охватывать те вопросы, с которыми преподаватель сталкивается в школе.

**Ключевые слова:** *преподавание математических дисциплин, учебный процесс, нейролингвистическое программирование.*

## 1. INTRODUCTION:

It is assumed that students who are now finishing a pedagogical university at the age of 22-23 years will, on average, work as teachers for 40-45 years. In this time, new fields will emerge in mathematical science that currently does not exist; school teaching will change in many ways, it will include such problems of mathematics that our students may not yet be studying (Arkhangelsky, 1980; Avramidis and Norwich, 2002; Frade et al., 2013; Stockero, 2013; Van Zoest et al., 2016; Stockero et al., 2017; Bayanov et al., 2019). Therefore, future mathematics teachers have to be taught not only those branches of mathematics that are currently important but also those regarding which there is reason to believe they will develop shortly or will become the basis of future branches of science. In other words, this means that the thinking of students must be developed in such a way that later they can learn new sections of mathematics that they may need to teach in the future at school, even if they do not study them at the moment (Miguel and Mendes, 2010; Mendes, 2013; Mendes and Silva, 2018).

The main trends characteristic and

necessary for the preparation of future mathematics teachers as future specialists (Kravets, 2011; Cohen, 2011; Schejbal, 2012; Stockero and Van Zoest, 2013; Leatham et al., 2015; Seitova et al., 2016; Seitova et al., 2018):

- from a “knowing person”, armed with a system of knowledge, skills, to “a person prepared for life”, that is, a person capable of active and creative thinking, and acting, self-developing intellectually, morally and physically;

- from the concept of “Education for life” to understanding the need for education through life, the psychological readiness for further education and retraining, including the willingness to take them at face value, and not as a life catastrophe, should be formed in the course of modern professional education;

- development of initiative; initiative can guarantee success in life, a person’s mobility, readiness to solve various kinds of problems, the action must not only be maintained but also purposefully, consistently formed;

- from knowledge to competencies; the knowledge-centric model of education doesn’t

satisfy the real needs of the development of society and the individual; it is necessary to involve students as future specialists in the process of hard and diverse work in teaching, acquiring the skills necessary to study the material, it is important to promote cooperation.

Against the backdrop of significant social changes since the early nineties, the education system in many countries of the world is undergoing reform (Pligin, 1997; Breitigam and Karakozov, 2004; Vilensky et al., 2004; Dalinger, 2014; Maslova, 2015; Anamova et al., 2019; Natolochnaya et al., 2020). The need for reforms is caused, in particular, by the fact that in higher education, for example, in Russia, as shown by the results of A.A. Verbitsky (Verbitsky, 1991), V.I. Kagan (Kagan and Chebyshev, 2000), Yu.T. Tatura (Tatur, 2000), O.V. Dolzhenko, V.L. Shatunovsky (Dolzhenko and Shatunovsky, 1990) and others, in some areas there was a significant gap between the global needs of society and the results of education; between the objective requirements of time and the general insufficient level of education; between professional orientation and the need of the individual to satisfy a variety of cognitive interests; between modern methodological approaches to advanced sciences and the archaic style of teaching (Abdudlina, 1976; Babansky, 1982; Yansufina, 2003; Peterson and Leatham, 2009; Bray, 2011; Herbst and Chazan, 2012; Mendes, 2012; Rauner, 2013; Uglev and Ustinov, 2014; Bartell et al., 2015; Lee and Cross Francis, 2018).

I.A. Kolesnikova gives a slightly different interpretation of the issue, analyzing innovation as a form of manifestation of a new quality of pedagogical reality, as a way of future development in pedagogy, thereby outlining the philosophical and teaching foundations for the development of teaching innovation as a scientific and practical field (Kolesnikova, 1999; National Council...2014; Lineback, 2015; Van Zoest et al., 2017).

The works of foreign authors cover certain theoretical and practical aspects of innovative processes as change processes in the educational system, based on various pedagogical innovations. The studies of American and English educators (H. Barnett, J. Bassett, D. Hamilton, N. Gros, M. Miles, R. Eden and others) analyze the management of innovative processes, the organization of changes in education, the conditions necessary for "activity" of innovations, planning of innovations, ways of regulation of pedagogical innovations.

The socio-psychological aspects of the distribution of innovations are well-developed. In essence, a typology of participants in innovation processes, their attitude to innovations, readiness to accept new ideas, reasons for the emergence and ways to overcome psychological barriers, factors for the development of innovative activity (K. Angelowski, E. Rogers, L.A. Korostyleva, O.S. Sovetova, A.M. Khon, M.V. Croz, L.M. Podlesnaya). The matters of managing innovative processes in education are considered in sufficient detail (A.P. Volchkova, O.G. Khomeriki, V.P. Kvasha, N.V. Konoplina, G.A. Krasyn, A.M. Voronin, V.F. But, etc.).

The purpose of the study is to test ways of implementing system-methodological support for innovation in the teaching of mathematical disciplines at the university with an experiment.

The general research question of this study was as follows: how effectively will the methodological training of future mathematics teachers increase based on the introduction of innovative techniques and teaching methods. How may the methodology of teaching mathematical disciplines in the conditions of innovation be improved?

## 2. MATERIALS AND METHODS:

In the course of the study, there were conducted an analysis of scientific and educational literature on the topic of research, a generalization of empirical material, modeling, questioning, testing, methodology with the choice of tasks, observation, recording the results of training and formation, a teaching experiment.

This study describes and analyses the experimental work on the implementation of the methodology for the formation of the readiness of future mathematics teachers to organize innovation in teaching mathematical disciplines at the university. In this case, the experimental work acts as the research method, which allows to scientifically substantiate, prove the idea that the implementation of the developed methodology provides an increase in the level of formation of the readiness of future mathematics teachers to organize innovation. The goals, the content of the stages, the results of the pedagogical experiment are revealed. The purpose of the experimental work was to test the hypothesis of the study. As a constructive basis for its design and implementation, the developed methodology for implementing the innovative orientation in the teaching of mathematical disciplines at the university was adopted following modern

requirements for the training of future specialists.

Two hundred thirteen people took part in the experimental work, including teachers of mathematics and full-time students, undergraduates, doctoral students, as well as young teachers of the university. Innovative work is represented by ascertaining, searching, and educational experiments.

The ascertaining experiment, wherein 120 people took part, was carried out in two stages. The first stage of the ascertaining experiment was carried out through a survey to identify among teachers of mathematics (70 people) their attitude to work in conditions of innovation, whether the development of changes is necessary for the advancement of the educational system, and whether specialists possess the required level of competence for the development of innovative works. Analysis of the results of the survey showed that only less than 50% of the tested teachers were able to positively answer the questions in the amount of 60% and above. The data obtained indicate a low assessment of the attitude towards the process of introducing innovations into the educational process. Moreover, it hints at a low level of formation of the necessary infrastructure for the development and implementation of changes. The second stage of the ascertaining experiment was to identify the levels of creation of the ability to introduce innovative approaches upon teaching mathematical disciplines for students (50 people) of the Faculty of Natural Sciences, specialty "Mathematics" before studying the subjects of methodological training (2nd year) and after (3rd year). Since in the 3rd year, students begin to explore disciplines of a methodological nature and further embark on pedagogical practice.

During the searching experiment, where full-time students and undergraduates took part (93 students), individual innovative teaching methods were tested, effective teaching methods were identified, the research hypothesis was clarified. The educational experiment was organized and conducted in vivo in the educational process of studying "Methods of Teaching Mathematics" by third-year students (47 people) of the Faculty of Natural Sciences of Zhetysu State University named after I. Zhansugurov (Kazakhstan, Taldykorgan).

The objectives of the educational experiment: 1) to identify the pedagogical conditions of the system-methodological support of the innovation in the teaching of mathematical disciplines at the university; 2) to prove the

efficiency of the developed methodology for the application of innovative technologies in the preparation of future mathematics teachers (on the example of the discipline "Methods of teaching mathematics"). Proof of the efficiency of the developed methodology for teaching future mathematics teachers to work in an innovative environment requires a description of diagnostic measures to determine the level of formation of the corresponding skill.

All procedures performed in studies involving human participants were following the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study.

### 3. RESULTS AND DISCUSSION:

As a diagnostic tool, a test consisting of 4 parts was developed, each of which corresponds to one of the indicators. In the first part of the test, students' knowledge in the field of mathematical training was assessed, in the second – their ability to solve typical problems in this area, and in the third and fourth – knowledge and skills that form the basis of the methodological unit of the formed ability. The maturity of each of the indicators was assessed on a 10-point scale. The indicator was considered mature if the student scored 9 or 10 points in the diagnostic event. The test results are presented in Table 1.

It was found that with increasing value  $h_0$ , the amplitude of displacements increases against the direction of the axis  $Ox$ , and the amplitude of displacements in the direction of the axis  $Ox$  decreases. With increasing value  $h_0$ , the maximum and average values of thermoelastic stress  $\sigma$  decreases.

Thus, it was established that only by changing the value  $h_0$ , (and not  $T_{amb0}$ ), i.e., by changing the environmental properties of the surrounding cross-sectional area where heat transfer occurs, the thermally stressed state of the rod under investigation can be changed. For data measured in an ordinal scale, it is advisable to use the homogeneity criterion 2. Objective: to determine the accuracy of coincidences and differences for a pair of experimental data measured in an ordinal scale using the uniformity criterion 2.

A description of the 2nd year group is a

point vector on an ordinal scale with  $L = 5$  different points (levels):  $n1 = (n1, \dots, n1L)$ , 30. A description of the 3rd year group is a point vector:  $n2 = (n2, \dots, n2L)$ , 20. At a significance level of  $\alpha = 0.05$ , using the uniformity criterion 2, check the null hypothesis  $H_0$ : differences in the distribution of students of groups of 2nd year and 3rd year by the maturity level of their methodological training in the conditions of innovation.

The empirical value of the criterion  $\chi^2_{ex} = 4.78346$ , the critical value  $\chi^2_{cr} = 9.46$ . As a result, a statistical conclusion is obtained. Since  $\chi^2_{ex} < \chi^2_{cr}$  the null hypothesis  $H_0$  is not rejected, the descriptions of the compared samples coincide at the significance level  $\alpha = 0.05$ . This means that the experimental results do not confirm the effect of the applied method with a confidence coefficient of 95%. Thus, it is necessary to increase the efficiency of teaching future mathematics teachers to advance innovation in the teaching process by implementing the author's methodology of applying innovative technologies in the learning process.

Students from the control and experimental groups were tested to determine the initial level of maturity of the ability to work in conditions of innovation. Implementation of the developed methodology took place upon studying the sections "Methods and forms of teaching mathematics" and "Psychological and pedagogical foundations of teaching mathematics". The following diagnostic measures were performed: 1) academic conferences and independent work, which were performed to assess the maturity of the indicators  $p1$  and  $p2$ , respectively; 2) questions of express-testing (from 0 to 2 points for each), which were developed with so as to assess the maturity of the indicator  $p3$ ; 3) individual work and homework, which was evaluated up to 4 points (0.2 for each), which were offered to students for assessment of the maturity of the indicator  $p4$ .

The indicator was considered formed if, according to the results of all diagnostic measures aimed at its evaluation, the student scored more than 7 points (from 8 to 10 inclusive). The results of the experiment are presented in Table 2. Paired comparisons shall be done. First, accuracy of coincidences and differences for a pair of experimental data shall be measured on an ordinal scale using the homogeneity criterion 2. At this significance level, the null hypothesis  $H_0: X1 = X2$  about the homogeneity of the two samples is checked. The algorithm is as follows:

1. For the two compared samples, the value

2 and the empirical value of the  $\chi^2$  criterion is calculated using the (Equation 1).

2. Further, this value is compared with a critical value (Equation 2), where  $\alpha$  – significance level,  $\chi^2_{(v,q)}$  – quantile of the Pearson distribution at level  $q$  with the number of degrees of freedom  $v$ .

As a result, a statistical conclusion is obtained. If  $\chi^2 > \chi^2_{cr}$ , then the null hypothesis is rejected, the descriptions of the compared samples vary at the significance level  $\alpha$ . If  $\chi^2 \leq \chi^2_{cr}$ , then the null hypothesis is not rejected; the descriptions of the compared samples coincide at the significance level  $\alpha$ . The statistical significance of the compared samples is verified at the significance level  $\alpha = 0.05$ . Then the critical value  $\chi^2_{cr} = \chi^2_{(4,0.95)} = 9.46$ .

Comparison of the experimental group before the start of the experiment with the experimental group after the end of the experiment. According to the original Table 2, to calculate the empirical value of the criterion according to the Equation (1) an auxiliary Table 3 shall be made.

Next, the empirical and critical values of the criterion (Equation 3) are compared. Since  $\chi^2 > \chi^2_{cr}$ , the null hypothesis is rejected, the descriptions of the compared samples differ at the significance level  $\alpha = 0.05$ . Comparison of the experimental group before the start of the experiment with the control group before the start of the experiment. According to data from the initial Table 2, to calculate the empirical value of the criterion according to the equation (1) an auxiliary Table 4 shall be created.

Then, the empirical and critical values of the criterion (Equation 4) should be compared. Since  $\chi^2 \leq \chi^2_{cr}$ , the null hypothesis is not rejected, the descriptions of the compared samples differ at the significance level  $\alpha = 0.05$ . Comparison of the experimental group before the start of the experiment with the control group after the end of the experiment. According to the data of the initial Table 2, to calculate the empirical value of the criterion according to the equation (Equation 1) an auxiliary Table 5 is created.

Further, the empirical and critical values of the criterion (Equation 5) are compared. Since  $\chi^2 \leq \chi^2_{cr}$ , the null hypothesis is not rejected, the descriptions of the compared samples differ at the significance level  $\alpha = 0.05$ . Comparison of the experimental group after the experiment with the control group before the experiment. According to the data from the initial Table 2, to calculate the empirical value of the criterion according to the

(Equation 1), an auxiliary Table 6 is created.

Next, the empirical and critical values of the criterion (Equation 6) are compared. Since  $\chi^2 > \chi^2_{cr}$ , the null hypothesis is rejected, the descriptions of the compared samples differ at the significance level  $\alpha = 0.05$ . Comparison of the experimental group after the end of the experiment with the control group after the end of the experiment. According to data from the initial Table 2, to calculate the empirical value of the criterion according to the Equation 1, an auxiliary Table 7 is created.

Then, the empirical and critical values of the criterion (Equation 7) are compared. Since  $\chi^2 > \chi^2_{cr}$ , the null hypothesis is rejected, the descriptions of the compared samples differ at the significance level  $\alpha = 0.05$ . Comparison of the control group before the start of the experiment with the control group after the end of the experiment. According to the data from the initial Table 2, to calculate the empirical value of the criterion according to the equation (Equation 1), an auxiliary Table 8 is created.

Further, the empirical and critical values of the criterion (Equation 8) are compared. Since  $\chi^2 \leq \chi^2_{cr}$ , the null hypothesis is not rejected, the descriptions of the compared samples differ at the significance level  $\alpha = 0.05$ . The results of paired comparisons are presented in Table 9. The critical value  $\chi^2_{cr} = 9.46$ . General results of the statistical analysis of paired comparisons are created. Sample descriptions coincide with a significance level of 5% for the following pairs of samples:

- “Experimental group before the start of the experiment” and “control group before the start of the experiment”;
- “Experimental group before the start of the experiment” and “control group after the end of the experiment”;
- “Control group before the start of the experiment” and “control group after the end of the experiment”;

Significant differences were identified for the following pairs of samples (95% confidence):

- “Experimental group before the start of the experiment” and “experimental group after the end of the experiment”;
- “Experimental group after the end of the experiment” and “control group before the start of the experiment”;
- “Experimental group after the end of the experiment” and “control group after the end of the

experiment”;

An analysis of the results shows that there are no significant differences at the beginning of the experiment between the experimental and control groups; however, at the end of the experiment, the results obtained in the experimental and control groups differ significantly. This is explained by the implementation of the methodology for the innovative technologies in the experimental group and the improvement of future mathematics teachers' methodological training.

#### 4. CONCLUSIONS:

Pilot testing is represented by the ascertaining, searching, and educational experiments. In the course of an ascertaining investigation (2016-2017), a survey was conducted among teachers of mathematics, undergraduates and doctoral students of the specialty "Mathematics," including young university teachers. The results of the ascertaining experiment became the basis for revising the purposes of the methodological and professional training of future mathematics teachers and made it possible to conclude on the necessity of improvement of the system-methodological support for teaching mathematical disciplines in higher education.

The training of a mathematics teacher should form them as a knowledgeable mathematician, as a person with a high pedagogical and general culture, who, by teaching, would educate the younger generation in the spirit of modernity. It can be assumed that the content of courses in a pedagogical university in mathematical disciplines should:

- 1) at a modern academic level, cover those matters that the teacher communicates at school;
- 2) provide for students' breadth of knowledge in mathematics, familiarize them with advanced mathematics and its problems as much as possible. Therefore, courses in higher mathematics should shed light on those fundamental issues of modern mathematics, which currently serve as its basis and determine its face. This will provide for a certain fundamental level of mathematical culture for a future mathematics teacher;
- 3) contain sufficiently rich applications of higher mathematics to science and technology. In the process of teaching, this will allow the future teacher of mathematics to provide the students with an idea of life application of the concepts and

processes that will be studied in the elements of higher mathematics at school;

4) teach to think mathematically, that is, to be able to solve mathematical problems and be able, in the simplest cases, to form various problems arising in other sciences in the language of mathematics;

5) ensure the educational nature of training, that is, the development of a common culture and the formation of the student's worldview and personality.

The tasks of the searching experiment (2016-2018) were solved in the course of teaching students: to construct the content of academic disciplines and find the main means of learning; identify indicators of development and develop diagnostic material.

In the course of the educational experiment (2018-2019), providing for the experimental training of students in the natural conditions of the educational process, was proven the efficiency of the proposed methodology for teaching future mathematics teachers in conditions of innovation.

Improving the methodological training of future specialists requires the introduction of a special course "Methodological support for the preparation of future mathematics teachers in an innovative orientation" in the program of training students of the "Mathematics" educational program, where scientific (educational) materials helping to form professional qualities and improve the methodological training of future specialists will be considered.

**RESUMO**

A aplicação dos métodos de ensino ao processo de aprendizagem na escola é determinada pelo fato de que cada professor ou desenvolvedor de currículo deseja que seus conceitos de ensino e a formação de princípios educacionais sejam implementados no ambiente educacional da maneira mais eficaz. Tais formas de interação são determinadas pelo fato de que cada professor procura integrar os elementos práticos da área disciplinar no processo educacional, tanto como estruturas metodológicas quanto como as formas complexas formalizadas de didática. O objetivo deste estudo foi identificar esse aspecto do problema pedagógico. A análise dos conhecimentos e habilidades anteriores mostra que o treinamento dos estudantes de classes seniores na área dos métodos de projetos de elementos de robótica tem um potencial significativo para a formação efetiva de competências de disciplinas. Os resultados obtidos no experimento pedagógico como um todo confirmaram a hipótese da pesquisa pedagógica: se aplicarmos o sistema especial de condições, formas e métodos didáticos para desenvolver as habilidades de design dos estudantes de classes seniores para projetar robótica e resolver os problemas e tarefas práticas, com base na construção e estudo da sequência de submodelos, isso aumentará a eficiência do ensino de design de robótica, formação de ideias sobre a natureza de modelo do conhecimento e desenvolvimento de suas habilidades cognitivas e criativas. Os resultados obtidos mostram que o curso de treinamento “Design de robótica como método de resolução de problemas aplicados” para estudantes ajuda a aumentar o nível de habilidades na área de tecnologia robótica dos estudantes de classes seniores no cada critério específico, o que confirma a justificativa pedagógica da introdução de condições didáticas identificadas e teoricamente justificadas para o desenvolvimento de habilidades de design de robótica em estudantes de classes seniores.

**ABSTRACT**

The application of teaching methods to the learning process at school is defined by the fact that every teacher or curriculum developer strives to ensure that his or her concepts of teaching and formation of the educational principles are implemented in the educational environment most effectively. Such forms of interaction cause the fact that every teacher strives to integrate the practical elements of the subject area into the learning process both as the exact structures and as the formalized complicated forms of didactics. This study aimed the revealing of this aspect of the pedagogical problem. The analysis of the previous knowledge and abilities shows that teaching the methods for the design of the robotics' elements to the senior school students has a significant potential for the active form of the subject competencies. The obtained results of the teaching experiment have generally proved the hypothesis of pedagogical research. If to apply a unique system of didactic conditions, forms and development methods of the senior school students' robotics design skills to robotic design and solution of

tasks and practical assignments based on the construction and research of the sequence of sub-models, then it will contribute to the increase in the effectiveness of the robotic design teaching, the formation of the students' ideas of the model nature of cognition, and the development of their cognitive and creative abilities. The obtained results show that teaching course 'Robotics Design as a Method for Solution of Application Tasks' to students contributes to the increase in the level of the senior school students' robotics design skills by each particular criteria, which proves the pedagogical rationale of introducing the revealed and theoretically substantiated didactic conditions for the development of the senior school students' robotics design skills.

## АННОТАЦИЯ

Применение методов обучения к процессу обучения в школе определяется тем фактом, что каждый учитель или разработчик учебной программы стремится к тому, чтобы его или ее концепции преподавания и формирования образовательных принципов были реализованы в образовательной среде наиболее эффективным образом. Такие формы взаимодействия обуславливают тот факт, что каждый преподаватель стремится интегрировать практические элементы предметной области в учебный процесс как в качестве методических структур, так и в виде формализованных сложных форм дидактики. Целью данного исследования было выявление данного аспекта педагогической проблемы. Анализ предыдущих знаний и умений показывает, что обучение методам проектирования элементов робототехники ученикам старших классов имеет значительный потенциал для эффективного формирования предметных компетенций. Полученные результаты педагогического эксперимента в целом подтвердили гипотезу педагогического исследования: если применить специальную систему дидактических условий, форм и методов развития навыков конструирования учащихся старших классов для робототехнического проектирования и решения задач и практических заданий, основываясь на построении и исследовании последовательности подмоделей, это будет способствовать повышению эффективности обучения робототехническому проектированию, формированию у учащихся представлений о модельной природе познания и развитию их когнитивных и творческих способностей. Полученные результаты показывают, что учебный курс «Дизайн робототехники как метод решения прикладных задач» для студентов способствует повышению уровня навыков робототехники старшеклассников по каждому конкретному критерию, что подтверждает педагогическое обоснование внедрения выявленных и теоретически обоснованных дидактических условий развития у студентов старших классов навыков конструирования робототехники.

## 1. INTRODUCTION:

To find the indicators of the level of senior school students' robotics design skills, it is going to consider the particular skills that are the components of the competence (Kyei-Blankson, 2014; Ali *et al.*, 2018; Anamova *et al.*, 2019; Wu *et al.*, 2018; Tuna & Ahmetoğlu, 2019; Harada, 2020). By the capability of the senior school students in the robotics design, it means the personal competence combining the knowledge and skills, providing an opportunity to set a task in a particular way:

- to choose the design objects and to find the interconnections between the components of the research process;

- to translate the developed concepts into the language of formulas and signs, to understand the algorithms and mathematical methods for the computation of the characteristics of a robotics model;

- to interpret the obtained data, and to

formulate the particular conclusions (Scherer & Beckmann, 2014).

In the context of the study, the structure of the robotics design competence is presented as an aggregate of three interconnected components: theoretical, practical, and personal (Danesi, 2016; Molchanova *et al.*, 2018; Caballero-Gonzalez *et al.*, 2019).

To define the indicators and the levels of the robotics design skills among the senior school students, the process of a senior school student's personal development was investigated (Miller *et al.*, 1995; Damaševičius *et al.*, 2018; Karpenko *et al.*, 2019). In this period of personal development, the primary type of individual activity is learning. In the senior adolescent age, learning is a specific kind of events, where the subject affected by specific external factors and results of his/her activities: acquires the social experience; knowledge; forms the opinions and the view of the world in general which results in the change of his/her behavior; psychic processes; personal traits (Turuntaev, 2018). The successfulness of

acquiring the learning skills, including the robotics design activities, depends on the level of the student's preparedness, so it was chosen the approach concluded in the transition from one level of differentiation to another as the base for the definition of the indicators of the skills' level – a more complicated approach that differs from the previous one (Nilsson & Pareto, 2010; Chekanova & Gazizov, 2019; Gerosa *et al.*, 2019; Bayanov *et al.*, 2019; Marengo *et al.*, 2019; Sarsar & Çakır, 2020).

To develop the program of active development of the robotics design skills among the senior school students at the study of natural mathematical disciplines, it is necessary to define the main indicators, criteria, and levels of these skills (Fessakis *et al.*, 2018; Stepanov, 2019; Haiguang *et al.*, 2020; Yudin *et al.*, 2020). In the context of our study, the development of a school student as an integral process was analyzed, which may be considered only concerning a particular system because it is the result of the action of its elements (Ko *et al.*, 2012; Rativa, 2018; Habib, 2020). If set the objective to study the development process of a particular component, this process should be presented in the form of a system, having divided it into the components and highlighting the environment (Dmitrieva *et al.*, 2018; Kvesko *et al.*, 2018; Kim & Kim, 2020). There is a gradual transition from one level to another, particularly:

- the sophistication of the structural elements causing the refinement of the structure itself;
- the creation of a perfect arrangement of the relationships between the structural elements;
- simultaneous improvement of the fundamental aspects and the structure itself.

## 2. LITERATURE REVIEW:

In the learning process at school, at any level, deal with the concepts, statements, and supplements of a theoretical nature (Daskolia *et al.*, 2018; Loureiro *et al.*, 2019). The digestion of knowledge connected with the robotics design is narrowed to the assimilation of a particular system of concepts, statements, and proofs (Yacsar, 2004). But the purpose of learning is concluded not only in the digestion of the theoretical knowledge, but also in the transfer of skills how to apply this knowledge not only in the metabolism of particular proofs, but also in the formation of the ability to reason, prove, and solve practical tasks (Pohjolainen *et al.*, 2018; Ponce *et al.*, 2019).

The analysis of the previous knowledge and abilities shows that teaching the methods for the design of the robotics' elements to the senior school students has a significant potential for active formation of the subject competencies (Barnes *et al.*, 2017). The intentional development of the senior school students' robotics design skills while solving the application tasks requires a mainly organized learning process and its provision with the methods (Ruth, 2018).

According to the results of the conducted research, it should be revealed the directions for the increase in the effectiveness of the education aimed at the development of the senior school students' robotics design skills in the learning process of the natural mathematical disciplines formed in the didactic conditions (Ramalho & Crato, 2012). Based on the theoretical analysis of the role and place of the method for the robotics design in the modern science, it may be stated that particularly this method and its methodology take one of the leading positions in the system of modern science, being a new universal component of the methodology in any science (Pohjolainen *et al.*, 2018). The main didactic principle is to ensure the compliance of the education to the current level of science. So teaching the basics of the method for the robotics design becomes highly relevant because learning the elements of this method implies not just the digestion of particular rules and ways of action, but the development of a specific form of thinking (Campos, 2013).

The entire process of development of natural science is the process of development of the model knowledge about the objects and processes (Sevinc & Lesh, 2018; Daniela and Lytras, 2019). Particularly during the acquisition of the natural disciplines, the models was created and equipped, learn their properties, and foresee the processes in a wide range of possible conditions (Larson, 2013; Stehling *et al.*, 2016; Eteokleous, 2019; Yang, 2019; Muñoz *et al.*, 2020). The particular means of solving the application tasks is the process of 'solving' the model. In this regard, teaching the robotics design to the students, on the one hand, qualitatively changes the particular approach towards the solution of the tasks, and on the other hand – develops the new type of thinking (Scherer & Beckmann, 2014; Guderian, 2017; Fonseca Ferreira *et al.*, 2018; Jäggle *et al.*, 2018; Oudeyer, 2019; Strutynska, 2019).

### 3. MATERIALS AND METHODS:

To reveal the similarities and differences in the characteristics of the experimental and control groups, the following hypotheses was formulated: the hypothesis of the absence of differences (null hypothesis) and the hypothesis of the significance of differences (alternative hypothesis). To choose the hypothesis (null or alternative), the statistical criteria are applied. Particularly, to measure the data by the order scale, it is reasonable to apply the Pearson's  $\chi^2$  (chi-square) criterion of homogeneity. The empirical value of the statistical criterion  $\chi^2_{emp}$  is calculated (Melis, 2005; Soliman, 2019).

To assess the effectiveness of the traditional (mediated) method and the one was suggested for the development of the knowledge and skills of the robotics design, the indicators of the increment in the initial level of the students' knowledge and expertise was used. At such an approach, the suggested didactic model is considered more productive, more increase in the level of experience, skills, and general intellectual development have been achieved as a result of its application. The correctness of the effectiveness assessment of implemented didactic model significantly depends on the extent of the correctness of the level of skills and knowledge as well as the positive changes among the students of the cognitive sphere. To quantitatively assess the set level, the notion of the information-sense element of the text (ISET), which is based on the structural properties of the educational information, was used. The level every student's knowledge and skills before and after the evaluation of the systematic system for the formation of the robotics design skills was assessed employing coefficient (Equation 1) where  $S$  is the general number of the earlier digested ISET,  $S_i$  – general number of ISET, which were digested and revealed by the  $i$ -student before the beginning of the experiment and after the formation stage.

The average value of the increment in the students' knowledge and skills taught by means of a corresponding methodical system is defined by the following equation (2). Where  $n$  is the number of students in the group,  $K_{1i}$  and  $K_{2i}$  are the similar values of the coefficients of the  $i$ -student's skills and knowledge revealed during the final and initial assessment, respectively.

The structure of our methods for effectiveness assessment of the methodical systems for the formation of the robotics design skills (suggested and traditional indirect ones)

consists of the following components:

1) the definition of the initial level of knowledge and skills and the mathematical development of each student of the experimental and control group;

2) the definition of the final level of the abovementioned parameters of each student in the experimental and control groups (after the teaching experiment);

3) the revealing of the absolute increment in the level of knowledge and skills, the fixation of the positive tendencies in the development of the cognitive sphere of each student of the experimental and control groups;

4) the computation of the average values of the initial and final levels of the knowledge and skills;

5) the computation of the average values of the absolute increment in the level of knowledge and skills, the fixation of the positive tendencies in the general and intellectual development;

6) the revealing of the relative increment in the level of knowledge and skills for the students of each group.

7) mathematical processing of the obtained results (comparison of the values of relative increments in the levels of knowledge and skills, as well as positive tendencies in the development of the cognitive sphere among the students of the experimental and control groups).

### 4. RESULTS AND DISCUSSION:

The changes in the level of the skills and knowledge of students are reflected in Table 1 and Table 2. The coefficients of the level of the robotics design skills were defined according to the equation (1). Where  $S_i$  is the number of digested elements of the knowledge for  $i$ -student,  $S$  is the general number of the knowledge elements containing in the suggested control work. The average coefficient is calculated according to the following equation (3). The average value of the increment in the level of knowledge and skills among the students of each group is computed according to the equation (2). Where  $K_{1i}$  is the coefficient of the level of the robotics design skills defined for  $i$ -student during the final control, while  $K_{2i}$  – during the initial control, respectively (Table 3), the effectiveness assessment of the teaching stage of the experiment may be presented as a diagram in Figure 1.

Let's calculate the scores in the control and

experimental groups. The average rating in the experimental group is  $x_1=77$ , in control one –  $x_2=63$ . The value of dispersions: in the experimental group –  $\sigma_1^2=14.318$ , in the control group –  $\sigma_2^2=16.667$ . The null hypothesis is formulated at the proposition that the deviation of the average values is accidental, i.e., equation (4). The alternative theory suggests that the teaching methods in the experimental group are more productive, i.e., equation (5).

At such a formulation of the alternative hypothesis, the one-sided control of the null hypothesis through the student's t-test is conducted. The statistical characteristic of the control of the null hypothesis is the normalized deviation of the average values (Equation 6), which is subject to the distribution of the student's probabilities with the number of freedom degrees  $k=n_1+n_2-2=206$ . The assessment of the average dispersion out of the group ones is equal to

$$\sigma^2 = \frac{\sum_{i=1}^m \sigma_i^2 n_i}{n_1 + n_2 - 2} = 16,138, \text{ then } t = 25.24.$$

The critical value of the one-sided student's t-test at the level of significance  $\alpha=0.05$  and  $k=206$  is equal to  $t_{0.95}(206)=1.97$ , which is less than the actual one. So, the null hypothesis is rejected. With the 0.95 probability, one may state that the methods applied in the experimental group are more effective. The coefficient of the effectiveness of the suggested methods, in this case, is defined according to the following equation 7. Where  $K_e$  is the coefficient value of the level of the E students' robotics design knowledge and skills according to the results of the final assessment, while C is the coefficient value for the control group. So, the result of the teaching stage of the experiment is the effective coefficient of our robotics design methodical teaching system for students, which is equally as follows  $\eta = \frac{0,488}{0,355} = 1,37$ .

The fact that the obtained values of coefficient  $\eta$  are equal to  $\eta>1$  shows the relative effectiveness of our systematic teaching system. In the process of the element-by-element analysis conducted by the program, the requirements that should satisfy the digestion of the students' knowledge and skills were defined. These requirements imply the knowledge of the essential attributes of the robotics design notions, and their connection and correlation with the other ones.

To test the effectiveness of the developed

educational model of teaching robotics design in the process of the experimental research, it should be defined the following criteria:

- 1) the changes in the emotional Motivation of the students towards learning robotics design;
- 2) the level of the robotics design skills among the students;
- 3) the effect of the suggested didactic model on the level of knowledge of the adjacent disciplines, such as mathematics, economics, and physics. Let's consider each criterion in detail.

Criterion 1: The change in the emotional Motivation of the students while learning robotics design. Parameter: The students' emotional Motivation. Testing method: Surveying students on their emotional Motivation before and after the experiment. Hypothesis: Teaching our developed educational model to the students will improve the emotional Motivation of the students from the experimental group, which will evidence the growth of their interest and the positive inner Motivation to the robotics design. Mann-Whitney U test. The experiment, according to the first criterion, was performed in three stages:

- 1) the development of the survey form for the definition of the emotional state of the students;
- 2) the research of the absence of the differences between the E and C groups before the experiment;
- 3) the research of the emotional state of the students of the E and C groups after the experiment.

Below is the description of each stage. Stage 1: The development of the survey form to define the students' emotional Motivation. The didactic model of teaching the robotics design method to the senior school students, which contains the motivational component of the learning process was developed, including as follows:

- the theoretical material reflecting the specificity of the application of the robotics design method in the learning process of the students;
- the application tasks by the natural science disciplines;
- the practical creative tasks, including the project works.

As a result, the creation of the positive inner Motivation for learning the robotics design method, and the growth of the interest in solving

the application tasks was expected. In order to investigate the effect of the motivational component on the students during the optional course learning, the survey form to define the students' emotional state based on the analysis of the psychodiagnostic methods for the social-psychological research was developed.

Stage 2: The research of the differences between the E and C groups before the experiment. Therefore, it is necessary to compare the average parameters of the emotional disposition of the students from the E and C groups towards learning the proprietary methodology in the form of a didactic model of the optional course 'Robotics Design as a Method for Solution of Application Tasks'. Let  $O_1$  and  $O_2$  be the survey of the students from the experimental group and from the control group respectively regarding their emotional state before the experiment. By applying the Mann–Whitney U test, let us test the equality  $O_1=O_2$  (by the example of the E and C groups of the 11<sup>th</sup> graders).

The number of students in the E group is 16 ( $n_1=16$ ), while in C – 19 ( $n_2=19$ ). Scores (minimum 3, maximum 12), set by the students of both groups to the experiment are shown in Table 4. According to the data of the table, let us find the average score separately for the E and C groups and denote them as  $X_{exp}$  and  $X_{cont}$  respectively.

Based on the average indicators  $X_{exp}=6.44$  and  $X_{cont}=6.47$ , it should be supposed that the emotional states in both groups are almost the same. In order to test this supposition, let us suggest two hypotheses:

1.  $H_0$  – differences between  $X_{exp}$  and  $X_{cont}$  are accidental (or they absent). So, our groups are similar.

2.  $H_1$  – differences between  $X_{exp}$  and  $X_{cont}$  are reliable and significant. They may be caused by a greater range of the individual indicators' values, and then it is necessary to measure either the control or the experimental group.

The testing order of the suggested hypotheses is as follows:

1. The data of both groups are united into a new table in the order of increasing indicators.

2. Each value of the obtained sequence receives its rank. If there are several similar numbers in the sequence, then the rule of the connected ranks is applied.

3. The sum of ranks ( $\sum R$ ) separately for the experimental ( $\sum R_{exp}$ ) and control groups ( $\sum R_{cont}$ ) was found (Table 5). It was found that

$\sum R_{exp} = 286,5$ . The U-test value according to the following equation 8 was calculated. Where  $n_1$  is the number of students in the experimental group;  $n_2$  is the number of students in the control group;  $n_{Rmax}$  – the number of students in the group with a larger sum of ranks;  $R_{max}$  – maximum rank-sum.

4. Using table 'Critical Values of the U-Test ( $p = 0.05$ )', the critical value of the U-test for  $n_1=16$ ;  $n_2=19$ :  $U_{crit}=92$  was found.

If  $U > U_{crit}$ , then  $H_0$  hypothesis is accepted. If  $U < U_{crit}$ , then  $H_1$  hypothesis is accepted. In our case,  $U=146.5$ . So,  $146.5 > 92$ . Therefore,  $H_0$  hypothesis is accepted: the differences between our groups are insignificant.

Stage 3: The research of the emotional Motivation of the students from the E and C groups after the experiment. Based on our supposition, the emotional state of the students from the experimental group should raise, which evidences the growth of their interest in the solution of the application tasks, and the formation of the positive inner motivation to the robotics design.

Let  $O^*_1$  and  $O^*_2$  be the survey of the students from the experimental and the control group respectively regarding their emotional state after the experiment. After the conduction of the teaching experiment, it is necessary to compare the average indicators of the emotional state of the students from the E and C groups in order to test that  $O^*_1 \neq O^*_2$ —the scores set by the students of both groups after the experiment are presented in Table 6.

After the experiment, the average score of the students' emotional state in the experimental group grew up to 7.88 scores ( $X^*_{exp}=7.88$ ), while in the control group, it became equal to 6.37 ( $X^*_{cont}=6.37$ ). If to base on the average indicators, then one may suppose that the positive emotional state in the experimental group grew from  $X^*_{exp}=6.44$  (before the experiment) to  $X^*_{exp}=7.88$  (after the experiment) not accidentally, but thanks to the learning process based on our methods. To test this hypothesis, let us suggest two following hypotheses:

1.  $H_0$  – differences between  $X^*_{exp}$  and  $X^*_{cont}$  are accidental. The experiment failed.

2.  $H_1$  – differences between  $X^*_{exp}$  and  $X^*_{cont}$  are reliable, significant. So, the emotional state in the experimental group grew thanks to the work of the teacher based on our methods.

The data of both groups are united into a

new table (see Table 7) in the order of increasing indicators. Each value of the obtained sequence received its rank. The sum of the ranks separately for the E and C groups was found. It was found that  $\sum R_{exp}^* = 371$ . According to the formula, the  $\sum R_{cont}^* = 257$

value  $U=69$  was calculated. And so,  $U < U_{crit}$  ( $69 < 92$ ), therefore the hypothesis  $H_1$  is accepted: the emotional state in the experimental group has increased thanks to the teacher's work based on our methods. The experiment is successful.

Criterion 2: The level of the students' robotics design skills. Parameter: The level of the E and C group students' robotics design skills. Testing method: The comparison of the final test results in the E and C groups. Hypothesis: The level of the students' robotics design skills (students' academic performance) increases thanks to their teachers' work based on our methods—Statistical Criterion: Student's t-test.

At the end of the academic year, the 11<sup>th</sup> graders of the E and C groups were offered to perform a final test. The results of the 11<sup>th</sup> graders' performed test are presented in Table 8. So, according to the results of the final test of the E students compared with the C group, one may make the following conclusions:

- 1) there are no 1 and 2 scores;
- 2) the number of students received from 3 to 5 scores decreased;
- 3) the number of students received from 6 to 10 scores increased.

The results of the E and C group students' final test are reflected in the form of a diagram in Figure 2. It should be combined the obtained results in accordance with the levels of the 11<sup>th</sup> graders' skills and present them in Table 9. Thus, in the E group compared with the C one:

- 1) the number of students with a low level of skills decreased by 18.6 %;
- 2) the number of students with a moderate level of skills decreased by 9.2 %;
- 3) the number of students with a sufficient level of skills increased by 25.7 %;
- 4) the number of students with a high level of skills increased by 2.1 %;
- 5) the qualitative parameter of the academic performance increased from 17.2 % to 45%.

The dynamics are reflected as a diagram in Figure 3. After the experiment, the average score

of the 11<sup>th</sup> graders' algebra academic performance increased from  $X_{exp}=4.9$  to  $X_{exp}^*=6.3$ , while the parameter of the C group remained unchanged ( $X_{cont}=4.8$ ;  $X_{cont}^*=4.8$ ). So, one may suppose that the academic performance of the 11<sup>th</sup> graders in the experimental groups grew not accidentally but thanks to their teachers' work based on our methods. To test this supposition, let us suggest two hypotheses:

1.  $H_0$  – differences between  $X_{exp}^*$  and  $X_{cont}^*$  are accidental. Experiment failed.

2.  $H_1$  – differences between  $X_{exp}^*$  and  $X_{cont}^*$  are reliable, significant. The algebra academic performance of the 11<sup>th</sup> graders in the experimental groups increased thanks to their teachers' work based on our methods.

The hypotheses will be tested through the student's t-test for independent samples. The testing procedure of the suggested hypotheses is as follows:

–  $\sigma_{exp}$  and  $\sigma_{cont}$  was calculated according to the following equation (9);

– the m value separately for the E and C groups was calculated according to the following formula equation (10);

– the value of the student's t-test was found according to the following equation (11);

– the number of degrees of freedom, which depends on the number of students in both samples (Equation 12) was found. In our case:  $n_1=n_2=435$ . Therefore,  $v=435+435-2= 868$ .

– using table 'Borders of the Student's T-Test Values', the level of statistical significance. If  $t_{emp} \geq t_{tabl}$  was defined, then hypothesis  $H_1$ ; if  $t_{emp} < t_{tabl}$  was accepted, then  $H_0$  was accepted.

The obtained data of the 10<sup>th</sup> graders' groups after the experiment are presented in Table 10. At the level of statistical significance  $p=0.001$ ,  $t_{emp} \geq t_{tabl}$  was ssen, i.e.  $13.49 > 1.96$ . So, hypothesis  $H_1$  was accepted: the experiment is successful. The acceptance of the alternative hypothesis provides the grounds to state that the experimental profession-oriented method of development of the robotics design skills among the 11<sup>th</sup> graders is more effective than the traditional one. At the end of the academic year, the 11<sup>th</sup> graders of the E and C group were offered to perform a final test. The results of the 11<sup>th</sup> graders' performed test are presented in Table 11. So, according to the results of the final test of the E students compared with the C group, one may make the following conclusions:

1) the number of students received from 2 to 5 scores decreased;

2) the number of students received from 6 to 10 scores increased;

3) more than half of the students received from 6 to 7 scores.

The results of the E and C group students' final test are reflected in the form of a diagram in Figure 4. It should be combined with the obtained results per the levels of the 11<sup>th</sup> graders' skills and present them in Table 12. Thus, in the E group compared with the C one:

1) the number of students with a low level of skills decreased by 10.2%;

2) the number of students with a moderate level of skills decreased by 18.1%;

3) the number of students with a sufficient level of skills increased by 24.9%;

4) the number of students with a high level of skills increased by 3.4%;

5) the qualitative parameter of the academic performance and increased from 17% to 45.3%.

The dynamics are reflected as a diagram in Figure 5. After the experiment, the average score of the E 11<sup>th</sup> graders' academic performance increased from  $X_{exp}=4.7$  to  $X_{exp}^*=5.9$ , while in the C group, the parameter remained almost unchanged ( $X_{cont}=4.9$ ;  $X_{cont}^*=4.8$ ). So, one may suppose that the 11<sup>th</sup> graders' academic performance in the experimental groups increased not accidentally but thanks to their teachers' work based on our methods. To test this supposition, let us suggest two hypotheses:

1.  $H_0$  – differences between  $X_{exp}^*$  and  $X_{cont}^*$  are accidental. Experiment failed.

2.  $H_1$  – differences between  $X_{exp}^*$  and  $X_{cont}^*$  are reliable, significant. The algebra academic performance of the 11<sup>th</sup> graders in the experimental groups increased thanks to their teachers' work based on our methods.

The hypotheses will be tested the same as the previous calculations through the student's t-test for independent samples. The obtained data of the students' groups after the experiment are presented in Table 13. At the level of statistical significance  $p = 0.001$ ,  $t_{emp} \geq t_{tabl}$  was seen, i.e.  $9.48 > 1.96$ . So, hypothesis  $H_1$  is accepted: the experiment is successful. The acceptance of the alternative hypothesis provides the grounds to state that the experimental profession-oriented method of development of the robotics design

skills among the students is more effective than the traditional one.

Criterion 3: The effect of the suggested didactic model on the level of knowledge in the adjacent disciplines, particularly: mathematics, economics, and physics. Parameter: The achievement by the E and C group students of the sufficient and high levels of the robotics design skills at the solution of the application tasks. Testing Method:

– the comparison of the final test results in the E and C group by the sufficient and high levels;

– the comparison of the E and C group students taking part in the creative tasks and defense of their own projects.

Hypothesis: teaching our methods to the students contribute to the increase in the sufficient and high levels of their robotics design skills, which shows the development of their interdisciplinary qualities in robotics design. High level of development of the students' interdisciplinary qualities is proved by their capability of solving more complicated application tasks, i.e. the achievement by them of sufficient and high levels of academic performance. The results of the conducted experiment by the second criterion showed as follows:

1) for the 10<sup>th</sup> graders:

– the number of the E students with the sufficient level of skills increased by 112 people (by 25.7 %) compared with the C ones;

– the number of E students with high level of skills increased by 9 people (by 2.1 %) compared with C.

2) for the 11<sup>th</sup> graders:

– the number of the E students with a sufficient level of skills increased by 108 people (by 24.9 %) compared with the C ones;

– the number of the E students with high level of skills increased by 15 people (by 3.4%) compared with the C ones.

## 5. CONCLUSIONS:

Teaching robotics design to students based on proposed didactic model has contributed to the increase in the number of students taking part in the creative tasks and defense of their projects in the E group compared with the C one by 121 people and 123 people respectively for the 10<sup>th</sup> and 11<sup>th</sup> graders. Thus, the hypothesis of the experiment by the third criterion has been

confirmed.

Accordingly, the obtained results of the teaching experiment have generally proved the hypothesis of the pedagogical research: if to apply a special system of didactic conditions, forms and development methods of the senior school students' robotics design skills to robotic design and solution of tasks and practical assignments based on the construction and research of the sequence of sub-models, then it will contribute to the increase in the effectiveness of the robotic design teaching, the formation of the students' ideas of the model nature of cognition, and the development of their cognitive and creative abilities.

The obtained results show that teaching course 'Robotics Design as a Method for Solution of Application Tasks' to students contributes to the increase in the level of the senior school students' robotics design skills by each particular criteria. This proves the pedagogical rationale of introducing the revealed and theoretically substantiated didactic conditions for the development of the senior school students' robotics design skills.

### RESUMO

Este trabalho descreve o procedimento para determinar tensões residuais na superfície usando o método mecânico e quatro métodos de endurecimento de amostras. A urgência do problema declarado no artigo se deve ao fato de que as tensões de tração superficial que surgem na fabricação de peças altamente carregadas podem reduzir significativamente as características mecânicas, de recursos e de fadiga dos produtos. O objetivo do estudo foi endurecer amostras de ligas de titânio e ferro-cromo-níquel para melhorar suas características de resistência, fadiga, recursos e determinar tensões residuais por remoção camada por camada das camadas estudadas por ataque eletroquímico. A determinação das tensões residuais da superfície foi realizada mecanicamente, utilizando um complexo de medição e cálculo durante a gravação contínua do metal a partir da superfície de teste da amostra, o que possibilitou medir as tensões residuais em diferentes profundidades e determinar a energia do estado de estresse da superfície. As tensões residuais foram calculadas a partir da deformação da parte restante da amostra com uma mudança na profundidade das camadas estudadas. O endurecimento das amostras foi realizado de quatro maneiras, a saber: endurecimento por ultrassom; cura por ultrassom + Rosler (processamento de vibração); Rosler (processamento de vibração) + cura por ultrassom; Rosler (processamento de vibração) + endurecimento por ultrassom. Os resultados do estudo mostraram que a superfície dos produtos é uma área mais fraca que a interna. Após a têmpera, surgem tensões compressivas na superfície de todas as amostras de ligas de titânio e ferro-cromo-níquel. O caso preferido de endurecimento é o segundo (endurecimento ultrassônico + endurecimento centrífugo). A presença de tensões compressivas residuais nas camadas externas dos produtos aumenta seu limite de fadiga em  $\pm 20\%$ . Os resultados do trabalho podem ser usados para fabricar produtos com altas características mecânicas, de recursos e de fadiga.

**Palavras-chave:** *tensões residuais, ultrassom, deformação, resistência, macro estresses.*

### ABSTRACT

This work describes the procedure for determining residual surface stresses using the mechanical method and four methods of hardening samples. The urgency of the problem stated in the article is due to the fact that surface tensile stresses arising in the manufacture of highly loaded parts can significantly reduce the mechanical, resource and fatigue characteristics of products. The aim of the study was to harden samples of titanium and iron-chromium-nickel alloys to improve their strength, fatigue and resource characteristics and determine residual stresses by layer-by-layer removal of the studied layers by electrochemical etching. The determination of surface residual stresses was carried out mechanically using a measuring and calculation complex during continuous etching of the metal from the test surface of the sample, which made it possible to measure the residual stresses at different depths and determine the energy of the surface stress state. Residual stresses were calculated from the deformation of the remaining part of the sample with a change in the depth of the studied layers. The hardening of the samples was carried out in four ways, namely: ultrasonic hardening; ultrasonic curing + Rosler (vibration

processing); Rosler (vibration processing) + ultrasonic curing; Rosler (vibration processing) + ultrasonic hardening. The results of the study showed that the surface of the products is a weaker area than the inside. After quenching, surface compressive stresses arise for all samples of titanium and iron-chromium-nickel alloys. The preferred case of hardening is the second (ultrasonic hardening + centrifugal hardening). The presence of residual compressive stresses in the outer layers of the products increases their fatigue limit by  $\approx 20\%$ . The results of the work can be used to manufacture products with high mechanical, resource and fatigue characteristics.

**Keywords:** *residual stresses, ultrasound, deformation, strength, macrostresses.*

## АННОТАЦИЯ

В данной работе описана процедура определения остаточных поверхностных напряжений с использованием механического метода и четырех способов упрочнения образцов. Актуальность заявленной в статье проблемы обусловлена тем, что поверхностные растягивающие напряжения, возникающие при изготовлении высоконагруженных деталей, могут существенно снизить механические, ресурсные и усталостные характеристики изделий. Целью исследования является закалка образцов из титановых и железо-хромоникелевых сплавов для улучшения их прочностных, усталостных и ресурсных характеристик и определения остаточных напряжений путем послойного снятия исследуемых слоев методом электрохимического травления. Определение поверхностных остаточных напряжений проводилось механическим методом с использованием измерительно-расчетного комплекса при непрерывном травлении металла с исследуемой поверхности образца, что позволило измерить остаточные напряжения на разных глубинах залегания и определить энергию напряженного состояния поверхности. Остаточные напряжения рассчитывались по деформации оставшейся части образца с изменением глубины залегания исследуемых слоев. Упрочнение образцов было проведено четырьмя способами, а именно: ультразвуковое упрочнение; ультразвуковое отверждение + рослер (виброобработка); Рослер (виброобработка) + ультразвуковое отверждение; Рослер (виброобработка) + ультразвуковое упрочнение. Результаты исследования показали, что поверхность изделий является более слабой областью, чем внутренняя часть. После закалки возникают поверхностные сжимающие напряжения для всех образцов из титана и железо-хромоникелевых сплавов. Предпочтительным случаем упрочнения является второй (ультразвуковое упрочнение + центробежное упрочнение). Наличие остаточных сжимающих напряжений во внешних слоях изделий увеличивает предел их усталости на  $\approx 20\%$ . Результаты работы могут быть использованы для изготовления изделий с высокими механическими, ресурсными и усталостными характеристиками.

## 1. INTRODUCTION:

When producing high-loaded details, one of the problems is the presence of surface tensile stresses (Gnyusov *et al.*, 2017; Hou *et al.*, 2018). They can substantially reduce the mechanical, resource, and fatigue characteristics of products (Wojtaszek *et al.*, 2016; Sakhvadze *et al.*, 2017; Pei & Duan, 2017; Huang *et al.*, 2018). The residual stresses exist in products in the absence of external actions. Three types of stresses are distinguished: macro stresses, micro stresses, and elastic stresses (Birger, 1963; Colegrove *et al.*, 2013; Hamad & Hassan, 2018; Astapov *et al.*, 2019a; Astapov *et al.*, 2019b; Cui *et al.*, 2020; Su *et al.*, 2020).

The main methods to determine residual stresses are mechanical and x-ray methods (Liu *et al.*, 2019; Sunder, 2016; Mohanty & Muduli, 2020). The mechanical process is most widely spread because it uses the same concepts of stresses and deformations of elastic body mechanics as those used when calculating the strength, rigidity,

and stability of details. The mechanical method of determination of residual stresses is based on cutting a sample from detail and subsequent layer-by-layer removal of the layers under investigation using electrochemical etching (Antolovich & Armstrong, 2014; Mustafin, 2006; Samarin *et al.*, 2019; Makarenko & Kuznetsova, 2019; Ding *et al.*, 2015).

The object of the work was to harden samples made of titanium and iron-chromium-nickel alloys for improvement of their strength, fatigue, and resource characteristics and determination of residual stresses by layer-by-layer removal of the studied layers using electrochemical etching.

## 2. MATERIALS AND METHODS:

The determination of residual surface stresses was made by the mechanical method using a measuring-calculating complex at the continuous etching of metal from the sample surface under investigation (Figure 1). Such a

plant measures residual stresses at different occurrence depths and determines the energy of surface stressed state, as well as makes it possible to optimize and control the stability of technological processes (Figure 2).

An experiment began by cutting a sample of standard sizes 50×4×2 mm (Figure 3). Then the sample was fastened into a holder (investigated face down); the holder and surface that was not subjected to etching were coated with paraffin. A steel ball was fastened in paraffin at the sample upper surface where deformation was measured (for contact with an inductive transducer). Then the holder with the sample was suspended to a carriage of the gage post, and the steel ball was brought to the inductive transducer to the point of maximal contacting. After this, the carriage was put into the electrolyte, and the etching process began. The balance became disturbed, causing the sample to deform. The residual stresses  $\sigma$  were calculated from the deformation of the remaining part of the sample, with changing occurrence depth of the layers studied (Birger, 1963; Gnatyuk, 2017; Lu *et al.*, 2018; Madzivhandila *et al.*, 2019).

### 3. RESULTS AND DISCUSSION:

#### 3.1. Determination of residual stresses

Let us consider the determination of axial residual stresses in a prismatic rod. We assume that, except for small areas at the ends of the rod, the residual stresses are constant along its length. To determine the residual stresses, we will sequentially remove the ABCD layers of materials (Figure 4) located in the zone of constant (along the length) stresses. The end sections are not removed; they are placed in the grips of the device.

The residual stresses  $\sigma$  in the surface layers of the initial detail were determined as a sum of stresses relaxed because of sample cutting from the detail ( $\sigma_d$ ) and a nonlinear component ( $\sigma_{n.l.}$ ) due to removal of layers from the sample surface (Equation 1). Depending on the sample thickness and value of mechanical stresses in the layers under investigation, layers separation from the detail may lead to its bending  $F_b$  and (or) change of its length  $\varepsilon_b$ . In this case, the variation of the initial stresses may be calculated as a linear component from their occurrence depth (Equation 2). Here  $E$  is the material modulus of elasticity;  $F_b$  is the bending because of sample cutting from the detail;  $K_0$  and  $K_1$  are the coefficients representing both form and sizes of the sample;  $K_{amp}$  is the

deformation amplification coefficient at different ways of fastening the sample and transducer in the process of cutting;  $\varepsilon_b$  is sample's relative extension at cutting.

Let us determine the residual stresses  $\sigma_{n.l.}$  acting in the rod at a distance  $a$  from the upper face of the rod (Figure 4). As a result of the removal of a layer of material with a thickness  $a$ , the remaining part of the rod is deformed under the action of stresses along the planes AB and DC.

Let stresses  $\sigma_{n.l.}(a)$  act at a distance  $\xi$  from the upper face. The bending moment  $M$  from stresses on the face AB relative to the middle of the rod height (point O) is (Equation 3), where  $b$  is the width of the rod. If the rod is bent by the concentrated moments  $M$  at the end, then the deflection is (Equation 4), where  $l$ ,  $h$  is the length and thickness of the rod, respectively,  $J$  is the moment of inertia of the cross-section (Equation 5). Neglecting the influence of axial forces on bending and taking into account (Equation 4) and (Equation 5), we find (Equation 6). Transferring the value  $(h-a)^3$  to the left side of the equality and differentiating the integral over the upper limit  $a$ , we obtain (Equation 7). From (Equation 7) at  $a = 0$  we obtain the formula for determining the residual stresses in the outer layer (Equation 8). After differentiating equality (Equation 7) with respect to  $a$ , we have (Equation 9). Integrating both sides of this equality, we obtain (Equation 10).

Given the relation (Equation 8), we can obtain the equation (Equation 11). The residual stresses varying with occurrence depth of the removing layers were calculated from the expression that takes into account not only the measured deformation for each current depth but also those residual deformations that relaxed due to the removal of the previous layers. The residual stresses component that varies with etching depth was calculated for prismatic samples in real time scale (Equation 11). Here  $L_{et}$  is the etched layer length;  $H$  is the sample thickness;  $F$  is the current value of sample deformation;  $\frac{dF}{da}$  is deformation variation with occurrence depth of the layers under investigation;  $a_i$  is the current depth of removed layers;  $\xi$  is the total current deformation.

When determining the residual stresses, the balance of forces over the sample thickness is violated because of etching of the layers studied that are in the stress state, and the sample bends. The stresses in the layer under investigation are calculated from that bending (deformation). In this

case, the balance of forces is restored, and partial relaxation of stress state occurs on the opposite side of the sample, in accordance with the bending moment (Sangid, 2013; Ahmad *et al.*, 2018; Aguilera-Correa *et al.*, 2019). Due to the specially chosen etching conditions, an exact calculation of the depth of etched layers is done from the amount of passed electric current according to Faraday's law (Equation 12).

Here  $a$  is the etched layer depth;  $t$  is the etching time;  $I$  is current in the etching series;  $\alpha$  is the effective electrochemical equivalent;  $\rho$  is the sample material density;  $B$  is the sample width. Shown in Figures 5 and 6 are the samples of titanium and iron-chromium-nickel alloys after etching. Figures 7 and 8 present the diagrams of surface residual stresses distribution in the samples of titanium (Li *et al.*, 2016; Kumar *et al.*, 2017; Kim *et al.*, 2013) and iron-chromium-nickel alloys (Jiang & Zhao, 2012; Debroy *et al.*, 2018). One can see that surface tensile stresses are present on samples of both types. The presence of such stresses (from 50 MPa and more) considerably reduces vibration and fatigue strength of the product (Malaki & Ding, 2015; Zhu *et al.*, 2017; Lin *et al.*, 2018; Wang *et al.*, 2020).

To solve the above problem, hardening of samples was performed in four ways: 1 – ultrasonic hardening; 2 – ultrasonic hardening + Rosler (vibratory finishing); 3 – Rosler (vibratory finishing) + ultrasonic hardening; 4 – Rosler (vibratory finishing) + ultrasonic hardening (He *et al.*, 2018; Sangid, 2013). In all four cases, the parameters of ultrasonic hardening remained unchanged: amplitude of 100  $\mu\text{m}$  and rated frequency of 20 kHz.

### 3.2. Centrifugal Hardening (Rosler)

Centrifugal treatment (Figure 9) is a high-performance method for finishing and hardening parts. The method of volumetric centrifugal treatment consists in the fact that the granular processing medium with the details is rotationally driven around the vertical axis so that it takes on the shape of a torus in which particles move along spiral paths. The machined parts are loaded into the working chamber and moved together with the working environment. Hardening is carried out due to the relative movement and interaction of the granular medium and the parts wetted by a liquid continuously supplied to the working chamber.

### 3.3. Ultrasonic hardening

The strain hardening of the surface layer of samples during ultrasonic hardening (Figure 10) is

carried out due to the kinetic energy of steel balls randomly moving in a spatially limited volume. The surface treatment takes place in the “cloud” of the working medium (balls) simultaneously from two sides. This type of treatment causes an increase in hardness of the surface layer by 18% and an increase in surface compressive stresses to 1000 MPa. The depth of the riveted layer is 20-25  $\mu\text{m}$ . Structural changes in the surface zones of the part cause an increase in the durability of products up to 1.5 times at cyclic stresses of 1650-2600 MPa. After hardening of samples in four ways, residual surface stresses were measured, and the diagrams of their distribution were obtained (Furuya, 2013; Kim *et al.*, 2016; Cai *et al.*, 2017; Zhan *et al.*, 2018; Su *et al.*, 2018; Klimenko *et al.*, 2018; Qiao *et al.*, 2019; Zhang *et al.*, 2020). The results of the measurements are presented in Figures 11 and 12.

One can see from figures that after hardening, there are surface compressive stresses for all samples made of titanium and iron-chromium-nickel alloys. The preferred case of hardening is the second (ultrasonic hardening + centrifugal hardening). In this case, the maximum compressive residual stresses reach 550 MPa at a depth of 50  $\mu\text{m}$ . The presence of residual compressive stresses in the outer layers of products increases their fatigue limit by  $\approx 20\%$ .

## 4. CONCLUSIONS:

The results of the investigations showed that the surface of products studied is a “weaker” area than the interior. Therefore, any process that leads to appearance and increase of surface compressive stresses will be positive for material operation. After quenching, surface compressive stresses arise for all samples of titanium and iron-chromium-nickel alloys. The preferred case of hardening is the second (ultrasonic hardening + centrifugal hardening). The presence of residual compressive stresses in the outer layers of the products increases their fatigue limit by  $\approx 20\%$ . The results of the work can be used to manufacture products with high mechanical, resource and fatigue characteristics.

## RESUMO

Compósitos são materiais multifásicos que possuem propriedades superiores de engenharia; a combinação de suas fases constituintes atinge essas propriedades. Os compósitos poliméricos reforçados por nanopartículas (NPCs) são novos tipos de compósitos que atraíram muita atenção recentemente e emergiram rapidamente como uma atividade de pesquisa multidisciplinar cujos resultados poderiam ampliar as aplicações dos polímeros em benefício de muitas indústrias diferentes. O objetivo da pesquisa é analisar o efeito da adição de diferentes porcentagens (10, 20 e 30%) de nanopartículas de sílica ao poliéster insaturado (UPE) e identificar a cinética de estabilidade térmica e decomposição para elas. Nesta pesquisa, os nanocompósitos foram preparados a partir de poliéster insaturado (UPE) misturado com diferentes porcentagens (10, 20 e 30%) de nanopartículas de sílica. As curvas de análise gravimétrica térmica (TGA) e calorimetria diferencial de varredura (DSC) foram obtidas a partir da degradação térmica calculada usando o Coats-Redfern. Os parâmetros cinéticos e termodinâmicos foram estudados para todas as amostras, apresentando um excelente coeficiente de correlação linear próximo à unidade usando o Minitab 16. Trabalho experimental mostrou que a degradação de compósitos obtidos a partir da análise termogravimétrica foi mais lenta que a UPE pura. A melhoria da estabilidade térmica foi atribuída ao teor de sílica. Além disso, o resultado mostrou que a decomposição sob o ambiente oxidativo para a UPE pura era muito mais rápida que o ambiente inerte.

## ABSTRACT

Composites are multi-phase materials that have superior engineering properties; the combination of their constituent phases achieves these properties. Nanoparticle-reinforced polymeric composites (NPCs) are new types of composites that have attracted a lot of attention recently and rapidly emerging as a multidisciplinary research activity whose results could widen the applications of polymers to the benefit of many different industries. The aim of research to analyze the effect of adding different percentages (10, 20, and 30%) of silica nanoparticles into unsaturated polyester (UPE) and identification of the thermal stability and decomposition kinetics for them. In this research, the nanocomposites were prepared from unsaturated polyester (UPE) mixed with different percentages (10, 20, and 30%) of silica nanoparticles. Thermal gravimetric analysis (TGA) and differential scanning calorimetry (DSC) curves were obtained from the thermal degradation computed by using the Coats-Redfern. The kinetic and thermodynamic parameters were studied for all specimens were presented an excellent linear correlation coefficient close to unity using Minitab 16. Experimental work was showed that the degradation of composites obtained from the thermal gravimetric analysis was slower than the pure UPE. The enhancement of thermal stability was attributed to silica content. Also, the result showed that the decomposition under the oxidative environment for the pure UPE was much faster than the inert environment.

**Keywords:** *Thermal decomposition, Thermal gravimetric analysis, Unsaturated polyester risen, Silica nanoparticles.*

المترابكات هي مواد متعددة الأطوار لها خصائص هندسية فائقة؛ يتم تحقيق هذه الخصائص من خلال الجمع بين تلك الأطوار المكونة لها. المترابكات البوليمرية المدعمة بالجسيمات النانوية (NPCs) هي أنواع جديدة من المترابكات جذبت الكثير من الاهتمام مؤخرًا وسرعان ما ظهرت كمنشآت بحثية متعددة التخصصات يمكن أن تؤدي نتائجها إلى توسيع تطبيقات البوليمرات لصالح العديد من الصناعات المختلفة. يهدف البحث إلى تحليل تأثير إضافة نسب مختلفة (20 و 30%) من الجسيمات النانوية للسيليكا إلى البوليستر غير المشبع وتحديد الثبات الحراري وحركية التحلل لهما. في هذا البحث، تم تحضير المترابكات النانوية من البوليستر غير المشبع (UPE) الممزوج مع نسب مئوية مختلفة (10 و 20 و 30%) من جسيمات السيليكا النانوية. تم الحصول على منحنيات كل من التحلل الوزني الحراري (TGA) والمسح الحراري التفاضلي (DSC) من التحلل الحراري المحسوب باستخدام تقنية Coats-Redfern. تمت دراسة المعلمات الحركية والديناميكية الحرارية لجميع العينات وتم تمثيل معامل ارتباط خطي ممتاز قريب من الوحدة باستخدام Minitab 16. وأظهر العمل التجريبي أن تحلل المترابكات التي تم الحصول عليها من التحلل الوزني الحراري كان أبطأ من البوليستر غير المشبع النقي. يعزى تعزيز الاستقرار الحراري إلى محتوى السيليكا. أيضًا، أظهرت النتائج أن التحلل للبوليستر غير المشبع النقي تحت البيئة المؤكسدة كان أسرع بكثير منه في البيئة الخاملة.

**الكلمات المفتاحية:** التحلل الحراري، التحلل الوزني الحراري، راتنج البوليستر غير المشبع، جسيمات السيليكا النانوية.

## 1. INTRODUCTION:

Poly condensation polymers considered very practical in several usages due to their price and easily fabricated, suitable mechanical property, and higher corrosion property (Atta *et al.*, 2005). It is widely employed mainly in the area of coating, electrical application, fabrication parts of automotive, and construction fields (Selly and Mark, 1988; Kramer, 1992; Giovanilton *et al.*, 2009).

Thermal analysis is a technique used to measure a physical property of a substance and/or its reaction product as a function of temperature. Differential scanning calorimetry (DSC) is a technique used to study the thermal transition of a polymer. A sum of essential physical changes in a polymer takes place when a polymer is heated, which can be measured via DSC. These involve the glass transition temperature (Tg), melting temperature (Tm), crystallization temperature (Tc), and degradation or decomposition temperature (TD). Also, chemical changes due to polymerization and degradation reactions and other reactions affecting the specimen can be estimated (Charles and Seymour, 2008; Pearce *et al.*, 1982).

Kinetic parameter and thermodynamic prosperities and thermal stability determined by utilizing thermal gravimetric analysis (TGA) and differential scanning calorimetry (DSC) which gives a very clear idea about the structure of the polymers and the behaviour of various composites under severe heat (Budrugeac *et al.*, 1996; Budrugeac, 1995).

Oxidative and thermal decomposition of polymers and composite usually occurs at higher temperature by the elimination of molecules along the polymer chain followed by random scission of the backbone chain; however, these changes produce more volatiles, gases and eventually all

the polymer convert to high molecules of polynuclear ring so-called chars (Regnier and Mortaigne, 1995; Bansal *et al.*, 1989; Gibson and Hume, 1995; Arie *et al.*, 1998). However, polyester decomposition occurs in two stages, in the first stage, the degradation of the backbone of the main chain occurs by ester change and hydrogen elimination and finally converts to volatiles, gases, and char because of its strong hydrogen bond prevent it from melting in the second stage (Mouritz and Gibson, 2007; Tagle *et al.*, 1992; Pielichowski and Hamerton, 1998).

There are numerous numbers of previous studies related to the kinetics of decomposition have been studied by many researchers, however, they concentrated on constant decomposition rate, activation energy and thermodynamic properties of different polymers and its different composite and they showed the enhancement in thermal stability of composites by using different inclusions for example:

Al-Bayaty and Farhan, (2015) studied unsaturated polyester resin (UPE) mixing with different weight percent 2, 4, and 6% of toner carbon nanopowder (TCNP) to prepare polyester composite. Non-isothermal decomposition kinetics of UPE and UPE/TCNP composites was carried out by utilizing thermogravimetric analysis (TGA). Kinetic parameters were determined for all specimens that were satisfactorily presenting good correlation with a linear correlation coefficient close to the unit using the SPSS package and were in a good agreement with published data. The experimental results show the decomposition of UPE/TCNP composites obtained from the thermal gravimetric analysis is faster comparing with those UPE specimens. This enhancement is attributed to the iron content in TCNP.

Thamer *et al.*, (2019) studied, the thermal analysis methods reported for the characterization

of epoxy/ Hexagonal Boron Nitride Nanoparticles (BNNPs) nanocomposites were conducted using Thermogravimetric Analysis (TGA), Differential Thermal Analysis (DTA) and Differential Scanning Calorimetry (DSC). Non-isothermal kinetics decomposition of epoxy and epoxy/BNNPs nanocomposites were carried out by utilizing Thermogravimetric Analysis (TGA). TGA and DTG curves obtained from the decomposition were analyzed using the Coats-Redfern method. Kinetic parameters were determined for all specimens that show a good correlation with the linear correlation coefficient, where Coats and Redfern's procedure was the best to result in reasonable estimates of the kinetic parameters.

Ferreira *et al.*, (2006) Novel aluminized E-glass fiber reinforced unsaturated polyester composites, formulated initially for enhanced thermal and electrical shielding properties, were evaluated in terms of their thermal performance. The thermal degradation of these specimens was analyzed using a thermogravimetric analyzer (TGA). All samples were decomposed under dry nitrogen (N<sub>2</sub>) at a flow rate of 40 ml/min to yield gases and solid char. Aluminized E-glass composites were compared alongside the unmetalled E-glass and unreinforced composite. The significant weight loss occurred between 200 and 400°C. The unreinforced polyester had a maximum weight loss, 1.25%/°C, happening at 360°C. For the aluminized and unmetalled E-glass composites, the maximum rate of weight loss was 0.34 and 0.55%/°C, respectively. Experimental results show the degradation of the aluminized E-glass composites obtained from TGA tests is higher compared to those of unmetalled E-glass fiber and unreinforced polyester composite. This improvement is correlated to the aluminum coating.

The aim of this current study was, therefore, to fabricate nanocomposite samples using the silica content (10, 20, 30) wt% with the unsaturated polyester resin to improve thermal stability and thermal decomposition of thermoset polyester using by Coats-Redfern method.

## 2. MATERIALS AND METHODS:

### 2.1. Composite fabrication

The materials employed to fabricate the nanocomposites are unsaturated polyester resin (UPE) as a matrix. It is a liquid with moderate viscosity, which can be cured to the solid-state by adding (Methyle EthyleKeton Peroxide, MEKP) as a hardener. At the same time, cobalt octoate acts

as a catalyst to accelerate the solidification process. The percentage of the hardener to the resin is (2%) while it is (0.5%) for the accelerator. Desirable physical properties, easily handled, quickly cured, and stable dimensions after solidification. The features of unsaturated polyester resin are given in (Table 1). Hardener: is a chemical material, which is added to thermosetting resin for the purpose of causing curing or hardening. The terms hardener and curing agent are used interchangeably. Note that these can differ from catalysts, promoters, and accelerators. Curing: To change the physical properties of the material (usually from a liquid to a solid) by chemical reaction, by the action of heat and catalysts, alone or in combination, with or without pressure. Accelerator: A chemical used to speed up a response or cure.

The term accelerator is often used interchangeably with the term promoter (Charles, 1975). Silica nanoparticles with a particle size of 100 nm were used as commercial fillers. The chemical composition of nano-silica is given in (Table 2). Atomic force microscopy (AFM) was used (CSPM scanning probe microscope) to measure the average particle size of nano-silica. The particle size distribution is shown in (Figure 1).

Samples of the polymer and nanocomposites at different Silica content (10, 20, and 30 %) are fabricated by cast molding. All content mixed thoroughly before casting, then the samples left at ambient temperature for 24 hr, and then cured, the specimens were left for 2 hr in an oven at temperature 60°C.

### 2.2. Kinetic theory

The Coats-Redfern method is a multi-heating rate application of the Coats-Redfern equation (Kim and Sea, 2005; Sperling, 2005) has been applied to study the kinetics of the decomposition of the polymer and its composite.

$$\ln \{[-\ln (1-\alpha)/T^2]\} = \ln(AoR/\beta Ea) \{1-(2R T / Ea)\} - (Ea/R T) \quad (\text{Eq. 1})$$

Where

$\alpha$  = The extent of the reaction

$\beta$  = The constant heating rate

$Ao$  = The frequency factor

$R$  = The universal gas constant

$T$  = The decomposition temperature

$Ea$  = The activation energy

By plotting  $\ln\{-\ln(1-\alpha)/T^2\}$  against  $1/T$

for each heating, rate gives a family of straight lines of slope  $-E/R$  Frequency factor directly determined from Y-axis intercept by substituting values of activation energies:

$$\text{Intercept} = \ln(AoR / \beta Ea) \{1 - (2RT / Ea)\} \quad (\text{Eq.2})$$

### 3. RESULTS AND DISCUSSION:

#### 3.1. Thermogravimetric analysis

TGA and DSC is a crucial tool to study the kinetics of thermal decomposition and to describe the way were the polymer degrades and to determine the melting point and glass transition temperature and to explore the thermodynamics of thermal and to demonstrate the stability. Thermal decomposition carried out at a constant heating rate of 10 °C/min in an inert atmosphere between 35-650°C.

Figure 2 shows TGA and DSC profiles for pure polyester resin under oxidative agent; it can be seen the polymer start in losing its weight initially about 6 wt% at a temperature between 190 and 300°C then start losing significant weight 60.9 wt% between 300 and 430°C. However, this represents the first stage degradation, while the second stage starts 405°C till 462°C with a weight loss of 9.97 wt%, then the char starts to gasify. From the DSC profile observed two peaks which represent exothermic decomposition, the first small peak at 407.3°C, which represents the backbone scission followed with a prominent peak at 478.9°C, which represents the gasification of char. Figure 3 shows the profiles of pure polyester under inert conditions were initial lose weight starts 237°C till 310°C with weight lose 5.5 wt% followed by the first stage with weight lost 73.2 wt% between temperature range 310°C to 437°C and the second stage lose 18.8 wt% which ends at 641.8°C, the DSC profile also showed two peaks first at 415°C and the second one at 435°C. Table 3 shows the mass loss of polyester pure and with various weight percent of Silica content. However, there is a difference in the activation energy of oxidative and nonoxidative agents. In oxidative, the activation energy is much lower than nonoxidative, as shown in (Table 4). This is because oxygen enhances the decomposition, consequently reducing activation energies of decay.

The effect of addition Silica filler at different percentages are shown in Figure 4, (Figure 5) and (Figure 6). However, it can be seen the thermal stability increases with increasing Silica content (Figure 6) differs completely than (Figure 2) and

(Figure 3) especially at the initial stage which start 327°C with initial mass loss of composite 5.5 wt% followed with first stage decomposition which ends at 443°C with mass loss 72.5 wt%, while the stage mass loss is 12.49 wt% which is considered much lower comparing with pure polyester (Figure 3). DSC profile showed two peaks; the first appeared at 399°C, while the second at 508.2°C which is considered much higher comparing with (Figure 3), this is because of increased thermal stability.

#### 3.2. The kinetic parameters

There are several methods to determine the kinetic parameters of the degradation process. However, the kinetic parameters were found by applying the Coats-Redfern method, as shown in Figure 7, a typical plot of  $\ln(-\ln(1-\alpha)/T^2)$  against  $(1/T)$  for oxidative thermal decomposition pure unsaturated polyester, for the first-order reaction. The method applied for pure unsaturated polyester, and its composites at different Silica content is shown in (Figure 8).

The thermodynamic properties were estimated by the following equations (3,4, and 5) (Straszko *et al.*, 2000; Silva *et al.*, 2004):

$$\Delta H = E - R T_{\text{peak}} \quad (\text{Eq. 3})$$

$$\Delta S = R [ \ln(h Ao/kbT_{\text{peak}}) - 1 ] \quad (\text{Eq. 4})$$

$$\Delta G = \Delta H - T_{\text{peak}} \Delta S \quad (\text{Eq. 5})$$

Where  $\Delta H$  is activation enthalpy,  $\Delta S$  is activation entropy,  $\Delta G$  is activation free energy of decomposition,  $T_{\text{peak}}$  is maximum peak temperature,  $h$  is Plank constant, and  $kb$  is Boltzmann constant. Table 5 shows the thermodynamics property of pure unsaturated polyester and its composites, according to the Coats-Redfern method used in determining kinetic data.

Figure 9 shows there is a linear relationship between activation energy,  $Ea$ , and Entropy,  $\Delta S$  with accuracy  $R^2=99.3\%$  (Turmanova *et al.*, 2008; Vlaev *et al.*, 2004). Table 5 shows that the activation energy increases with increasing entropy, and the positive values of internal energy mean the degradation process is not spontaneous (Al-Mulla, 2012).

### 4. CONCLUSIONS:

The thermal degradation of a silica-reinforced unsaturated polyester composite has

been successfully studied and experimentally compared to unreinforced polyester. UPE and UPE/silica were degraded in two stages, and almost 94% of the original mass was decomposed into volatiles and char. The activation energy of the nanocomposite materials was found to be higher than that of pure UPE in the oxidation environment by approximately 51.07% at 30%wt silica, and 19.12% higher than the pure UPE in the inert environment at 30%wt silica. Also, the entropy of the silica nanocomposites was higher than the pure UPE in oxidation and inert environment. DSC profiles of the silica nanocomposites showed there was a shift of decomposition peaks towards the right side because of enhancement of thermal stability for composite attributed to silica content as compared with pure UPE in oxidation and inert environment.

RESUMO

A cinética da oxidação do tetra-hidrofurano pelo N-cloro-p-tolueno sulfonamida de sódio no meio de ácido clorídrico foi estudada neste trabalho a temperatura de 308 K. A taxa de reação mostra uma dependência de primeira ordem em [CAT] e uma dependência em ordem fracionária, cada uma em [THF] e [H<sup>+</sup>]. A lei da taxa derivativa, adequada para resultados experimentais, é a Equação 24. A constante da taxa de primeira ordem foi avaliada a partir da relação entre o gráfico de Log [CAT] e o tempo. A variação da força iônica pela adição de perclorato de sódio (NaClO<sub>4</sub>) e íon cloreto no meio não mostrou efeito significativo na reação. A taxa de reação aumentou com constante dielétrica decrescente (D), enquanto a adição de p-toluenosulfonamida retarda a taxa de reação. A reação de oxidação do tetra-hidrofurano foi estudada a uma temperatura diferente. Foram estimadas as constantes de equilíbrio para a formação de ácido hipocloroso, ácido hipocloroso protonado e o complexo ácido hipocloroso protonado-THF e sua constante de decomposição. Além disso, a taxa constante para a lenta (etapa de determinação da taxa) e o parâmetro de ativação foram calculados. Um mecanismo adequado para a reação de oxidação do tetra-hidrofurano foi proposto com base no achado experimental. O mecanismo inclui a reação de espécies ativas (H<sub>2</sub>OCl) do agente oxidante com o tetra-hidrofurano em uma etapa rápida para dar o complexo (X). Este complexo será então transformado em complexo (X̄) em passo lento e depois em γ-butirolactona em outro passo rápido.

ABSTRACT

The kinetics of tetrahydrofuran oxidation by sodium N-chloro-p-toluene sulfonamide in the hydrochloric acid medium was studied in this work at 308 K. The reaction rate shows a first-order dependence on [CAT] and fractional-order dependence each on [THF] and [H<sup>+</sup>]. The derivative rate law, which suitable for experimental results, is Equation 24. The first-order rate constant has been evaluated from the relationship of the plot of Log [CAT] versus Time. The variation of the ionic strength by the addition of sodium perchlorate (NaClO<sub>4</sub>) and chloride ion on the medium showed no significant effect on the reaction. The reaction rate raised with decreasing dielectric constant (D), while the addition of p-toluene sulfonamide retards the rate of reaction. The oxidation reaction of tetrahydrofuran have been studied at a different temperature, The equilibrium constants for the formation of hypochlorous acid, protonated hydrochlorous acid and protonated hydrochlorous acid-THF complex and its decomposition constant have been estimated. Also, the rate constant for the slow (rate-determining step) and the activation parameter have been calculated. A suitable mechanism for the oxidation reaction of tetrahydrofuran was proposed based on the experimental finding. The mechanism includes the reaction of active species (H<sub>2</sub>OCl) of the oxidizing agent with the tetrahydrofuran in a fast step to give the complex(X). This complex will then transformed into complex (X̄) in slow step then to γ-butyrolactone in another fast step.

المخلص

تمت دراسة حركية أكسدة رباعي هيدروفيوران بواسطة N-chloro-p-toluene sulfonamide في وسط حامض الهيدروكلوريك وعند درجة حرارة 308 كلفن. بينت النتائج أن معدل سرعة التفاعل يعتمد على تركيز الكلورامين-T (الرتبة الأولى) ويعتمد على تركيز كل من تيترا هيدروفيوران وأيون

الهيدروجين (الرتبة كسرية)، وأن قانون سرعة التفاعل المشتق والذي يتلائم مع النتائج العملية موضح في المعادلة (24). تم حساب ثابت سرعة لتفاعل الرتبة الأولى من رسم العلاقة بين لوغاريتم [CAT] مقابل الزمن ووجد أن تغير الشدة الأيونية بإضافة بيركلورات الصوديوم ( $\text{NaClO}_4$ ) واختلاف أيون الكلوريد ليس له أي تأثير على ثابت سرعة التفاعل، بينما يرتفع معدل سرعة التفاعل مع تناقص ثابت العزل الكهربائي (D) وعند إضافة ناتج التفاعل  $\text{p-toluene sulfonamide}$  يؤدي ذلك إلى نقصان معدل سرعة التفاعل. تمت دراسة حركية أكسدة تيترا هيدروفيوران في درجات حرارية مختلفة وتم تقدير ثوابت التوازن لتكوين حامض الهيكلوروس، حامض الهيدروكلوريك البروتوني، معقد حامض الهيدروكلوريك البروتوني - THF وثابت تحلله وحساب ثابت سرعة تفاعل الخطوة البطيئة والمعاملات الترموديناميكية، وأخيراً اقترحت ميكانيكية ملائمة للتفاعل اعتماداً على النتائج العملية والتي تتضمن تفاعل الجزء الفعال ( $\text{H}_2\text{OCl}$ ) من المادة المؤكسدة [CAT] مع تيترا هيدروفيوران بسرعة ليعطي المعقد (X) والذي يتحول ببطء إلى المعقد (X) والذي يعطي بدوره  $\gamma$ -بيوتيرولاكتون بخطوات سريعة أخرى لاحقة.

الكلمات المفتاحية: THF، حركية، أكسدة، ميكانيكية، كلورامين-T، وسط حامضي.

## 1. INTRODUCTION

The chemistry of sodium N-chloro-p-toluenesulfonamide ( $\text{p-CH}_3\text{-C}_6\text{H}_4\text{SO}_2\text{-NClNa}\cdot 3\text{H}_2\text{O}$ ), well known as Chloramine-T (CAT or  $\text{RNCINa}$ ), is a member of the aromatic sulphonyl haloamines. It is expected to behave as an oxidation agent in acidic and alkaline media and delivers a two-electron change in the reaction medium to form (p-TSA;  $\text{RNH}_2$ ) and ( $\text{NaCl}$ ). The oxidation potential of CAT/ $\text{RNH}_2$  modify with the pH of the medium and increase with reducing the pH of the medium (Campbell and Johnson, 1978; Banerji *et al.*, 1987). Different reaction species were recorded depending on the medium acidity (pH), such as N-Chloro-p-Toluenesulfonamide,  $\text{RNHCl}$ , Dichloramine-T,  $\text{RNCl}_2$ ,  $\text{HOCl}$ ,  $\text{H}_2\text{OCl}$  and  $\text{RNH}_2\text{Cl}$  in acid medium,  $\text{OCl}$  and  $\text{RNCl}$  in alkaline medium. Chloramine-T has been vastly utilized as a volumetric reagent in the direct and indirect determination of several compounds (Kotthoff and Belcher, 1957; Jennings and Crit, 1974; Berka and Zvka, 1965).

Limited kinetic studies of these reactions are reported, such as oxidation of cyanide, thiocyanate, hexacyanoferrate, sulfoxide,  $\alpha$ -hydroxy acid, primary and secondary alcohol, phenols, catecholamines, aldehyde, ketones, aldoses, formic acid, ether and substituted of amino acid (Mahadevappa and Gowda, 1979; Ahmed *et al.*, 1980; Mushran and Agrawal, 1971; Mahadevappa *et al.*, 1979; Mushran and Agrawal, 1971; Naidu *et al.*, 1988; Natarajan and Thiagarajan, 1975; Balasubramanian and Thiagarajan, 1975; Jagadeesh and Vaz, 2005; Agrawal and Mushran, 1973; Sanehi and Mushran, 1973; Agrawal and Mushran, 1972; Hassan and Al-Joraycee, 1989; Hassan and Saeed, 2012; Saeed, 2011). In addition, chlorination reactions of aniline, toluene, furan-2-carboxylic acid, and acetanilide have also been studied (Ramanujam and Trieff, 1977; Radhakrishnamurti *et al.*, 1982; Hassan and AL-Hatim, 1995; Hassan and Noor, 2010).

Tetrahydrofuran (THF) is usually utilized

as a reaction medium and also as a chemical reactant. So it is interesting to explore the oxidation kinetics of the THF by CAT in the acidic medium as a solvent as well as, the oxidation of THF was studied by several oxidizing agents like chromium trioxide, lead tetraacetate, ruthenium tetroxide to the corresponding  $\gamma$ -butyrolactone (Lee, 1969; Metsger and Bittner, 2000; Che *et al.*, 1991).

Little attention has been paid to the mechanism oxidation of these reactions. Also, these reactions are free of side reaction and usually give quantitative yields of pure product.

Also, the oxidation of THF by CAT has not been reported in the literature. Therefore, it is the benefit of studying the oxidation of THF by Chloramine-T in acidic medium.

## 2. MATERIALS AND METHODS

### 2.1. Materials

Tetrahydrofuran (Fluka<sup>TM</sup>) of spectra grade (99.5%) used as received. Chloramines-T was purified by the method of Morris *et al.* (1948). CAT aqueous solution was standardized by the iodometric method. All other chemicals of analytical grade. The ionic strength was kept at high constant values utilizing concentrated  $\text{NaClO}_4$  solution.

### 2.2. Kinetic measurements

In glass stoppered Pyrex<sup>TM</sup> tubs, the reaction was carried out beneath pseudo-first-order conditions by keeping with [CAT] in low compare with [THF], which kept in high concentration. In a typical kinetic experiment appropriate of THF, hydrochloric acid, methanol, sodium perchlorate, and water, which was placed in a thermostated – water bath for about 30 min at 308 K. The reaction was initiated by rapidly adding the desired amount of CAT solution to the mixture. CAT solution followed by drawing samples (5 mL)

at different periods to the irrigating solution (2 M sulfuric acid, 5% KI, and water) in the volumetric flask. The absorption of the free iodine at 353 nm was recorded using the C-Cell spectrophotometer. Finally, the pseudo-first-order rate constant  $k$  was obtained from the slope of the straight line of  $\text{Log} [\text{CAT}]$  versus time.

### 2.3. Stoichiometry

Reaction solutions, including different proportions of CAT and THF, were equilibrated at 308 K in the existence of (0.2 M) for one day. Appreciation of the unreacted of chloramine-T showed that one mole of the (THF) expended two moles of (Chloramine-T), the suggested reaction can be seen in Equation 1.

The reaction product p-TSA was identified by chromatography, utilizing benzyl alcohol saturated with water with 0.5% vanillin in one percentage of HCl solution in ethanol as a spray reagent ( $R_f = 0.905$ ). The oxidation product of THF is  $\gamma$ -butyrolactone was identified by infrared spectroscopy and characterized by reaction with hydrazine hydrate to form hydrazide derivative (Saleh and Ayoub, 2014). Pure  $\gamma$ -butyrolactone has a boiling point of 205 °C.

## 3. RESULTS AND DISCUSSION

### 3.1. Results

The kinetics of tetrahydrofuran oxidation by chloramine-T was inspected in different initial concentrations of reaction acid media.

#### 3.1.1. Reactant Concentration Effect

At a high concentration of the reactant with a fixed acid concentration, plots of  $\text{Log}[\text{CAT}]$  or  $\text{Log}[\text{CAT}]_0/[\text{CAT}]_t$  with time were linear ( $r > 0.9975$ ) pointing first – order reliance of  $[\text{CAT}]$  rate. Table 1 included the rate constants of pseudo-first-orderer. The values of  $k$  raise with reactant concentration. Plots of  $\text{Log } k$  with  $\text{Log} [\text{THF}]_0$  is linear ( $r = 0.99$ ) with a slope of (0.42). Figure 1 illustrated the reactant concentration in fractional-order.

#### 3.1.2. Hydrogen ion Concentration Effect

The rate constant of reaction increased with increasing the concentration of hydrogen ion. The rate constant of fractional-order was obtained from the straight-line slope ( $r = 0.9939$ ) of  $\text{log } k^{-1}$  versus  $\text{log}[\text{H}^+]$ , which dependence on hydrogen

ion concentration. No detectable reaction observed between THF and CAT under varying conditions at 308 to 335 K in sulfuric acid rang (0.2-0.5 M) and perchloric acid medium in the range (0.2-0.6 M). The amount of unreacted CAT remained unchanged after 3 hours of the reaction mixture, which contained 0.01 M CAT, 1.4 M THF, and  $\mu = 0.125$  M.

#### 3.1.3. The chloride ion, ionic strength, and p-TSA concentration-effect

Extension of chloride ion from (NaCl) (0.25–0.45 M) at constant  $[\text{H}^+]$  has no effect on the rate (Table 2). At a different concentration of the ionic strength (0.125–0.625 M of  $[\text{NaClO}_4]$ , no significant effect was seen on the rate (Table 2). Extension of the reaction product of p-toluene sulfonamide (0.025–0.125 M) to the reaction mixture retards the reaction rate significantly. The plot of  $\text{Log } k$  versus  $\text{Log} [\text{p-TSA}]$  was linear ( $r = 0.9963$ ) with a slope of nearly inverse unity (Table 2).

#### 3.1.4. The solvent compositions effect

At different compositions of aqueous methanol, the reaction rate has been studied. The rate of the reaction raises with an increase a methanol content (Table 2). Linear plots ( $r = 0.9948$ ) with a positive slope of  $\text{log } k_1$  versus  $1/D$  was seen (where D is the dielectric constant of the medium) (Jouyban *et al.*, 2004). The negligible effect of methanol oxidation was seen in the control experiments with methanol (Table 3).

#### 3.1.5. Temperature effect

At different temperatures (298 K – 318 K), the reaction has been studied. The pseudo-first-order rate constants and the activation parameters of oxidation of THF by CAT are given in Table 4.

### 3.2 Discussion

The dependence of rate on acidity (Table 1) could be a consequence of protonation of either chloramine-T or tetrahydrofuran. The oxonium ions formed by protonation of THF would not readily undergo an electrophilic attack, and hence extensive protonation of the ether would decrease the rate of reaction. However, the enhancement of rate by  $\text{H}^+$  ion indicates that the unprotonated ether is the reacting species, and consequently, the decrease in substrate concentration through the formation of oxonium ions can be neglected.

Chloramine-T behaves like a strong electrolyte, in aqueous solution and dissociates as Equation 2 (Bishop and Jennings, 1958).

In an acid medium, mono Chloramine-T (RNHCl). N-Chloro-p-Toluenesulfonamide has been formed, when the anion contracts a proton (Equation 3).

Due to the disproportionation of free acid, it has given rise to p-toluenesulfonamide ( $\dot{R}NH_2$ ) and Dichloramine-T ( $\dot{R}NCl_2$ ) (Equation 4).

Hypochlorous acid HOCl has been formed from the free acid hydrolyze and Dichloramine-T (Equations 5 and 6). Hypochlorous acid produced can be ionized as Equation 7. Protonation of the free acid in pH < 3 has also been reported Abdulsalam *et al.* (2018), to give (Equation 8). The protonated monochloramine-T ( $RN^+H_2Cl$ ) hydrolyzed to give protonated hydrochlorous acid and  $\dot{R}NH_2$  as Equation 9. In acid solution, free chlorine ( $Cl_2$ ) has been found in the existence of chloride ion as Equations 10 and 11.

The possible reactive species in acidified CAT solution are  $\dot{R}NHCl$ ,  $\dot{R}NCl_2$ , HOCl,  $Cl_2$ , and probably ( $H_2OCl$  and  $\dot{R}N^+H_2Cl$ ) as a result of  $k_a$  values of chlorine which equal to  $4.66 \times 10^{-4}$ . A variation of experimental conditions will often favor one reactive species rather than others. No significant effect on the rate constant was seen when varying ionic strength adds to the reaction mixture by the addition of a concentrated solution of ( $NaClO_4$ ). The reaction rate enhances significantly by decrease the dielectric constants of the medium (by adding methanol). For all aspects mentioned above, the reaction proposed takes place between a neutral molecule and a positive ion. In the opinion of this, either  $H_2O^+Cl$  or  $RN^+H_2Cl$  are likely to be the important probable reactive species. Since the reaction rate shows an enhancement by  $H^+$  ion and retardation by the addition of reaction product p-TSA (Table 2),  $RN^+H_2Cl$  can be excluded as the oxidizing species. Under the supposition,  $H_2O^+Cl$  is the reactive species.

The reaction mechanism can be proposed in schemes 1 and 2. The reaction intermediates X and  $\bar{X}$  involved in schemes 1, 2, and 3 are oxo – chloro derivative of the substrate. Rao *et al.* (1970) have reported the formation of such oxo-halo derivative during the oxidation of THF by sodium bromate. If  $[CAT]_t$  is the overall efficient concentration of CAT, as Equations 12, 13, 14 and 15. Reparation for  $[HOCl]$  and  $[H_2O^+Cl]$  from Equations 14 and 15 respectively in to Equation 13 one obtains Equation 16.

Then substitute for  $[H_2O^+Cl]$  from Equation 15 into equation 14 it is obtained Equation 17. Substituting for  $[H_2O^+Cl]$ ,  $[\dot{R}NHCl]$  and  $[HOCl]$  from Equations 15–17 respectively in to Equation 12 and solution of  $[X]$ , it is obtained Equation 18 (from the slow step of scheme 1).  $[\dot{R}NH_2]$  is negligible compared with other terms in the denominator, then Equation 19 becomes Equation 20. Since the rate =  $k_1[CAT]_t$ , Equation 20 can be converted into Equations 21, 22 and 23. The constant  $k_4$ ,  $K_2$  and  $K_3$  were computed from these equations while the equilibrium constant  $K_1$  can be evaluated using scheme 2 derived law.

The concentration of the total effective of CAT is  $[CAT]_t = [\dot{R}NHCl] + [H_2O^+Cl] + [X]$  and the reaction rate of the slow step =  $k_8[X]$ . Substitute  $[\dot{R}NHCl]$  and  $[H_2O^+Cl]$  obtained from step (i) and (ii) leads to rate law Equation 24. By negligee, the term  $[\dot{R}NH_2]$ , the rate =  $k_1[CAT]$ , Equation 24 can be transformed into Equations 25 and 26. Equations 18 and 24 indicate first-order reliance of  $[CAT]_t$  rate, and fractional-order reliance of each  $[H^+]$  and  $[S]$  rate. Comparing the constants in both schemes 1 and 2, we get that  $k_4 = k_8$ ,  $K_3 = K_7$  and  $K_1K_2 = K_6$ , So Equations 25 and 26 can be written as Equations 27 and 28.

According to Equations 22 and 23, Figure 1 and Figure 2 show the plots of  $1/k_1$  versus  $1/[S]$  ( $r = 0.9949$ ) and  $1/[H^+]$  ( $r = 0.9939$ ) respectively were linear. Form the intercept of  $1/k_1$  versus  $1/[S]$ . The value of  $k_4$  was obtained as  $1.4 \times 10^{-3} \text{ sec}^{-1}$ . Substituted this value in the value of intercept of the plot of  $1/k_1$  versus  $1/[H^+]$  (Equation 23)  $K_3$  was obtained as (7.1). The value of  $k_4$  and  $K_3$  were substituted in the slope of plot  $1/k_1$  versus  $1/[H^+]$ .  $K_2$  value was obtained as (0.546). Then, substitute the value of  $K_4$  and  $K_3$  in the slope of the plot  $1/k_1$  versus  $1/[S]$  (Equation 26). The value of  $K_6/K_1$  was obtained as 0.43, and the value of  $k_1$  is obtained as (0.765) (were  $K_1 = \dot{K}_1/[H_2O] = (1.38 \times 10^2)$ ). Finally, the constants  $K_1$ ,  $K_2$ ,  $K_3$ , and  $k_4$  were utilized to calculate the rate constant under different conditions using Equations 21 and 28, respectively. The calculated rate constants were listed in (Table 5). As can be seen, there is an excellent agreement between the rate values indicating the correctness of the suggested scheme and the derived rate laws. Since the reaction preset a fractional-order relay on  $[S]$ , Michaelis–Menten kinetics was used to calculating the rate constant  $k_4$  from the slop step. The activation parameters reaction rates were calculated by the use of Arrhenius plots of  $\log k_1$  with  $1/T$  (Table 4).

Scheme 3 shows the THF oxidation by CAT, The intermediate of complex (X)

establishment by the electrophilic. The attack of protonated hydrochlorous acid  $\text{H}_2\text{O}^+\text{Cl}$  on the oxygen of the THF gives oxo-chloro derivative of THF ( $\text{X}^-$ ). Elimination of  $\text{H}^+$  and then hydrolysis with the elimination of  $\text{H}^+$   $\text{Cl}^-$  to give  $\alpha$ -THF alcohol. The last will then interact with the second active  $\text{H}_2\text{O}^+\text{Cl}$  molecule in the fast step to give the product  $\gamma$  – butyrolactone.

The derived rate law and the suggested mechanism are confirmed by the following experimental finding. The solvent composition has been changed in different methanol content in the methanol-water mixture. The effect of the solvent on bimolecular reaction has been discussed by Geng and Wei (2007), Laidler and Landskroener (1956), and Amis (1955). Also, this topic and other theories have been illustrated by Entelis and tiger (1976). Equation 29 has been developed for the limiting case of the head-on approach of an ion to the dipolar molecule.

A linear relationship between  $\log k_1$  and  $1/D$  was suggested for the addition Equation 29 with a positive slope for the relationship of negative ion and dipole or between two dipoles. Further, the rate constant of the first order slightly rose with increasing the initial concentration of Chloramine-T (Table 1). This reaction deactivation may result from the formation of small amounts of  $\text{NaClO}_4$  inside reaction, as Equations 30 and 31.

Finally, the suggested mechanism was supported by activation energy and parameter values. The high positive value of enthalpy  $\Delta H^\ddagger$  and activation free energy  $\Delta G^\ddagger$  refer to the slight solvation of the transition state while the negative values of entropy  $\Delta S^\ddagger$  propose the figuration of the activated complex with some reduction in the freedom molecule's degree.

#### 4. CONCLUSIONS

THF is an inert solvent, and it can be easily oxidized under certain conditions. The kinetics of the THF oxidation process is carried out by the formation of  $\text{HOCl}$  in the hydrochloric acid medium at 308 K.  $\text{HOCl}$  has acquired the hydrogen ion to form  $\text{H}_2\text{OCl}$ , which interacts with THF to gives the intermediate compound which in turn gives the final product ( $\gamma$ -butyrolactone). The reaction rate was first-order dependence on  $[\text{CAT}]$ , fractional-order dependence each on  $[\text{THF}]$  and  $[\text{H}^+]$ . No significant effect of the medium ionic strength was seen on the reaction. The inverse relationship was seen between the reaction rate and the dielectric constant ( $D$ ). The equilibrium constants have been suggested for the formation of hypochlorous acid,

protonated hydrochlorous acid, and protonated hydrochlorous acid-THF complex. The reaction mechanism was proposed and found consistent with the observed kinetics.

#### 5. ACKNOWLEDGMENTS

The authors are thankful to the Department of Chemistry, College of Education for Pure Sciences, the University of Mosul for funding and supplying laboratory facilities.

### RESUMO

Os corpos hídricos são os meios mais vulneráveis em termos de impacto causado pelo homem e a coleta de informações de monitoramento sobre o estado da biota e o regime hidroquímico é obrigatória de acordo com as recomendações da Convenção-Quadro da Água. O artigo trata dos arranjos necessários para o monitoramento e análise integrados de bancos de dados analíticos hidrobiológicos e ambientais para fins de prognóstico e remediação em pontos de observação da água afetados por objetos tecnogênicos quimicamente perigosos produzidos pelo homem (armas químicas). O objetivo deste artigo foi apresentar dados de monitoramento hidrobiológico e hidroquímico de rios na área de objetos perigosos fabricados pelo homem (armas químicas), conforme recomendado pela Convenção-Quadro da Água, para uma descrição comparativa das reações da biota aquática europeia aos efeitos do estresse. Foi validado o uso de índices hidrobiológicos e de diversidade biológica para registrar o impacto antropogênico na água. Os recursos dos dados analíticos ambientais para análise adicional da dinâmica das especificações de monitoramento foram identificados. Os parâmetros de escala do monitoramento hidrobiológico com o cálculo da diversidade  $\alpha$ , índice de Shannon e índice de saprobidade devem ser baseados em um exame completo da vegetação e flora aquáticas e semi-aquáticas. A análise do impacto antropogênico de um objeto artificial quimicamente perigoso na região de Bryansk (Federação Russa) em ecossistemas aquáticos por um longo período de tempo usando o método de bioindicação (que consiste na avaliação da diversidade de espécies, cálculo do índice de Shannon e índice de saprobidade da água) revelou que o componente tecnogênico do impacto dos pontos de referência nos cursos de água é mínimo.

### ABSTRACT

Water bodies are the most vulnerable mean in terms of human-made impact, and the collection of monitoring information on the state of biota and the hydrochemical regime is mandatory per the recommendations of the Water Framework Convention. The paper deals with the necessary arrangements for integrated monitoring and analysis of hydrobiological and environmental analytical databases for prognostic and remediation purposes at water observation points affected by human-made chemically hazardous technogenic object (chemical weapons). The purpose of this paper was to present data of hydrobiological and hydrochemical monitoring of rivers in the area of hazardous human-made objects (chemical weapons) as recommended by the Water Framework Convention for a comparative description of the reactions of European aquatic biota to stress effects. The use of hydrobiological indices and indices of biological diversity to record the anthropogenic impact on water has been validated. The features of environmental analytical data for additional analysis of monitoring specifications dynamics have been identified. The scale parameters of hydrobiological monitoring with the calculation of  $\alpha$ -diversity, Shannon index, saprobity index should be based on a complete examination of aquatic and semi-aquatic vegetation and flora. The analysis of the anthropogenic impact of a chemically hazardous human-made object in the Bryansk region (Russian Federation) on aquatic ecosystems over a long period of time using bioindication method (which consists in the assessment of species diversity, calculation of the Shannon index and water saprobity index) revealed that the technogenic component of the impact of reference points on watercourses is minimal.

## 1. INTRODUCTION:

The safety of the population in the operation of hazardous technogenic facilities in the Russian Federation and worldwide is a priority task, the solution of which depends on the planning and implementation of integrated environmental monitoring studies, including those conducted at water bodies (Anischenko, 2013; Ashikhmina, 2002, p. 442). A chemically hazardous technogenic object (chemical weapons storage and disposal facility) was in operation for a long time on the territory of the Bryansk region, which is the old-developed region of the Russian Federation.

Water bodies are the most vulnerable objects in terms of human-made impact. Thus, the collection of monitoring information on the state of biota and the hydrochemical regime is mandatory following the recommendations of the Water Framework Convention and is relevant in European countries (Alrumman *et al.*, 2016; European Parliament and Council of the European Union, 2000; Ruiz Jimenez *et al.*, 2011).

When analyzing databases on the current and prospective state of any water bodies, it is necessary to take into account additional environmental factors determining the state of aquatic and semi-aquatic communities, and first of all, the ions of biogenic elements. The presence of ions of biogenic elements, quickly migrating in water, accelerates the development of plant biomass, and also proves to be a limiting and toxic condition for their development (Adesuyi *et al.*, 2015; Mursaleen *et al.*, 2018).

When the facilities make the environmental impact for storage and disposal of chemical weapons, the phosphate ion is recognized as the marker ion for any habitat. Therefore, the detection of an excess amount of this ion in the environment indicates the need for additional monitoring of security systems at the enterprise. Exceeding the maximum permissible concentrations of phosphate ions can be diagnosed in waters based on biomass growth and by increased biodiversity, for example, of pleistophytic communities. A close relationship has been established between such biological indicators as  $\alpha$ -diversity, Shannon index, saprobity index with the concentration of ammonium cation and nitrate ions; dominant biomass and saprobity index are associated with the concentration of phosphate ions (Barinova *et*

*al.*, 2016; Chappuis *et al.*, 2014; Glibert, 2014; Mikulyuk *et al.*, 2011).

In the process of a long-term assessment of any hazardous human-made objects in terms of habitat components, experience in landscapes of the Non-Black Earth Area of the Russian Federation will be in demand, as it is aimed not only at identifying the state of natural ecosystems, but also at revealing the processes of their degradation, providing control of long-term effects (accumulation and transformation in environmental components) of toxic substances and products of their destruction. Bioindicative indicators of aquatic macrophyte communities of small watercourses under the anthropogenic pressure will complement large-scale global hydrobiological studies (Barinova, 2017a; Ostroumov, 2010; Saloua *et al.*, 2017).

The purpose of this paper was to present data of hydrobiological and hydrochemical monitoring of rivers in the area of hazardous man-made objects as recommended by the Water Framework Convention for a comparative description of the reactions of European aquatic biota to stress effects.

## 2. MATERIALS AND METHODS:

Large-scale monitoring of the environment with an integrated focus and analysis of the results was carried out on the premises of this facility at 121 reference points from 2005 to 2016 (Anischenko, 2013; Rybalsky *et al.*, 2007, p. 1144). After the completion of the production cycle, the database of surveys, including those at 5 water reference points, is in demand to optimize observations, assessment, forecast, as well as to arrange remediation measures that are actively deployed on the territory of a chemically hazardous object. The studies of watercourses in the area of a dangerous technogenic object in the Russian Federation were carried out in 2011-2016.

A map of the location of observation points and the location of rivers in the Pochep district of the Bryansk region is shown in Figure 1.

Ecological, production and indication works were carried out based on route survey, on floristic and production analysis of aquatic and semi-aquatic river plants in rivers, as well as on describing the flora of aquatic and semi-aquatic plants; the species was determined taking into

account generally accepted determinants (Karpov and Savostin, 2003, p. 243; Pechenyuk, 2004, p. 129). The nomenclature of species of vascular plants is indicated by the work of S.K. Cherepanov (1995, p. 992).

The aquatic vegetation was surveyed at the reference points of the chemical weapons disposal facility (object 1204) Russian Federation, this vegetation being subject to a powerful anthropogenic impact. The results obtained during the monitoring were to be used for the rehabilitation of water bodies and watercourses.

In the course of the study of aquatic biota, such methods were employed as route, geobotanical methods (according to the recommendations of J. Braun-Blanquet International School (Braun-Blanquet, 1964, p. 865), hydrobiological methods (product definition, calculation of biodiversity indices), statistical methods, the descriptions of which are shown below. To determine the abundance of aquatic plants and the overgrowing of objects, methods of ecological profiling were used on the transects located along-shore and across the entire size of the water body (Karpov and Savostin, 2003; Ramensky, 1909).

The distribution schemes of plant communities were compiled on the basis of maps of the survey area, according to V.G. Papchenkov (Papchenkov, 2003). When geobotanical descriptions are made on the ground, the boundaries of water cenoses were distinguished according to their physiognomic and ecological principles. The sizes of test plots for cenoses descriptions are from 1 to 4 m<sup>2</sup> or within the natural boundaries of communities (Mirkin, 1997). The obtained characteristics of aquatic macrophyte communities were compared to the data of researchers conducted in Europe and Asia (Barinova, 2017b; Chappuis *et al.*, 2012, 2011; Parsons *et al.*, 2011). The names of syntaxons correspond to the code of phytosociological nomenclature, made under the approach of J. Braun-Blanquet (Braun-Blanquet, 1964; Weber *et al.*, 2000).

To measure the biomass on trial plots, from 2 to 4 angle sites of 0.25 m<sup>2</sup> each were laid, the net primary output of hydrophytes was calculated taking into account hydrobiological methods (Mirkin, 1997; Papchenkov, 2003). Floristic diversity is estimated as the number of species on the site of a standard size, as well as the average number of species in the syntaxon coenoflora (Karpov and Savostin, 2003; Shitikov *et al.*, 2003). The uniformity of species is determined using

Simpson and Shannon indices, which were calculated according to standard formulae, with the definition of some statistical characteristics (Lakin, 1990, p. 352; Magarran, 1992, p. 184; Shannon and Weaver, 1998, p. 117; Shitikov *et al.*, 2003, p. 463). The basic ions of biogenic elements were determined by generally accepted standards and were compared with sanitary and hygienic standards (Ministry of Health of the Russian Federation, 2003).

Stationary observation sites are selected following the state environmental monitoring sampling system since information is needed on the background ecological conditions (of air, water, soil). Stationary sites are located according to the following principle: the boundary of the zone of protective measures, ½ of the radius of the zone of protective measures.

The description of plant communities based on the reference points of a chemically dangerous human-made object is presented below.

At point 110, the Costa River, there are communities of *Lemno-Spirodeletum polyrhizae* W. Koch 1954 em. Müll. Et Görs. 1960. Communities are spread in the form of small spots along the backwaters of the river from the depth of 0.2 to 0.7 m. The soil is slightly silty. The total projective cover is 50%.

The coenoses of the association *Lemnetum trisulcae* Kelh. Ex Knapp et Stoffers 1962 with the Far East *Lemna trisulca* are found in the impounded river stretches having a depth of up to 0.7 m. They endure only a weak current and are formed when the illumination is at least 50% of the total. The projective cover is up to 80%. The area of distribution is up to 3-5 m<sup>2</sup>.

Communities of association *Lemno-Hydrocharitetum morsus-ranae* Oberd. 1957, are confined to shallow areas, and described along the banks of the backwaters (mainly up to a depth of 0.6 m), on the stream openings. The total projective cover is from 65%.

The association *Potamogetonetum natantis* Soó 1927, is distributed on silty substrates at a depth of 0.8-1.3 m. *Potamogeton natans* forms the basis of phytocenoses with a projective coating of 75%. Communities are located at a distance of 3-5 meters from the water rim and often have an elongated oval shape. Association *Polygonetum natantis* Soó 1927, these associations are confined to habitats with sandy soils. The distribution depths of phytocenoses are up to 0.95 m. Communities do not form extensive

vegetation, they are encountered in separate «inclusions» along the bank. They are formed when the illumination is from 50 to 100%. The total projective cover of plants is low: from 30 to 65%.

Semi-aquatic communities are mainly formed by the following association communities. The communities of association *Typhetum latifoliae* Nowiński 1930 are common in the riverside strip under study, they are composed of high-grass helophyte - broad-leaved cattail. Plants form small spots, grow to a depth of 0.5 m with silt soils. The total projective cover is up to 90%. The communities of association *Phragmitetum australis* Savnič 1926, are formed along the river banks, and often form a solid «wall» of plants. Semi-aquatic communities grow on medium silty soils, the total projective cover of species is 98%.

Communities of the association *Sagittario sagittifoliae-Sparganietum emersi* Tüxen 1953, are two-tiered, and are composed only of gelophytic species growing on heavily silty soils under conditions of significant lighting of up to 90-100%.

Communities of the association *Rorippo-Phalaridetum arundinaceae* Kopecký 1961, are two-tiered with a total projective cover of up to 100%. They are formed on silty soils, and on the coast – on heavy clay loam.

At point 142 - the Semchanka River there are communities of the association *Lemno-Spirodeletum polyrhizae* W. Koch 1954 em. Müll. Et Görs. 1960, which are distributed throughout the profile of the study area to a depth of 0.4 m with slightly silty soil. The total projective cover is 40%. The communities of Ass. *Elodeetum canadensis* Egler 1933, are distributed in small spots in shallow waters at shallow depths of up to 0.35 m, on silty soils.

Phytocenoses of ass. *Lemno-Sagittarietum natantis* Taran et Tyurin 2005, LW: *Sagittaria sagittifolia*, *Lemna minor*, were registered in areas with sandy-silt soil, and with illumination from 60 to 90%. The total projective cover is from 30 to 65%.

The semi-aquatic communities dominating in the coastal strip are listed below: *Rorippo-Phalaridetum arundinaceae* Kopecký 1961, *Phragmitetum australis* Savnič 1926, *Butometum umbellati* Philippi 1973 which are formed in the shallow waters of the explored river habitats; they are single-tier, monodominant communities, sometimes with a small mixture of floating manna grass. The total projective cover is up to 65%.

Communities of Ass. *Oenanthera aquatica-Rorippetum amphibiae* Lohmeyer 1950, are widely distributed in riverside shallow waters to a depth of 0.3 m in well-lit habitats with silty soils.

In conditions of point 78 - in the Horn River - communities of associations *Lemno-Spirodeletum polyrhizae* W. Koch 1954 em. Müll. Et Görs. 1960, *Lemno-Hydrocharitetum morsuranae* Oberd. 1957, *Potamogetonetum natantis* Soó 1927 are formed.

Communities of Ass. *Ceratophylletum demersi* (Soó 1928) Egler 1933, are registered in the shallow places of the river backwater. Water depths are insignificant - mostly up to 0.5 m. The soil has substantial silt deposit. Association communities occupy the entire water column to the very bottom.

The association *Potamogetonetum lucentis* Huek 1931, the total projective cover of plants in the community is from 60 to 95%. These communities are described in the river to a depth of 1.5 m. The soil in the reservoir is the most diverse: from sandy to heavily silty. Communities evolve when illuminated from 60 to 100%.

The semi-aquatic communities are few in terms of the composition of the cenoses participating in the establishment of vegetation: ass. *Typhetum latifoliae* Nowiński 1930, *Oenanthera aquatica-Rorippetum amphibiae* Lohmeyer 1950, *Sagittario sagittifoliae-Sparganietum emersi* Tüxen 1953.

Association *Equisetetum fluvialitis* Nowiński 1930, is formed on silty soils, in the backwaters of the river to a depth of 0.3 m with a single-tier structure. The total projective cover is small - 45%.

### 3. RESULTS AND DISCUSSION:

The survey of macrophytes, as well as semi-aquatic plants in the biomonitoring system, is a recommended direction for collecting data for the monitoring base, since these objects are highly informative, they are distributed as background ones in aquatic habitats, and have high accumulative capacities (Barinova, 2017a, 2017b; Bolpagni et al., 2012; Bornette and Puijalon, 2011).

Monitoring indicators of the status of water macrophytes and saprobity indices, which form the basis of hydrobiological monitoring in any water objects, are presented for aquatic and semi-aquatic communities during the period of active

observations and active production cycle at the chemical weapons disposal facility.

Hydrobiological indices are determined as indicators of biological diversity in reference points (Table 1, Table 2).

The analysis of the reference points obtained as a result of water biomonitoring using the bioindication method indicates a favorable state of the environment, corresponding to its background state.

The species diversity of macrophytes and semi-aquatic vegetation is high, the Shannon index is significant. The species composition is represented by typically river species of 6 ecological groups. The human-made impact on the watercourse is minimal. The studies of saprobity showed the absence of oxygen starvation, significant overgrowth of the river; the water is clear. The quality of water and the condition of the water body, assessed according to the biomass and dominants productivity, is favorable and characteristic of natural hydrocenoses. The research results did not reveal the impact of a man-made object on the water flow of reference points.

Saprobity indices are shown in Table 3.

The studies of saprobity showed the absence of oxygen starvation, significant overgrowth of the river; the water is clear. The quality of water and the condition of the water body, assessed according to the biomass and dominants productivity, is favorable and characteristic of natural hydrocenoses. The research results did not reveal the impact of a human-made object on the water flow of reference points.

The saprobity indices calculated when conducting monitoring studies in other years using aquatic macrophytes are shown in Table 4.

The studies of saprobity showed the absence of oxygen starvation, significant overgrowth of the river; the water is clear. The quality of water and the condition of the water body, assessed according to the biomass and dominants productivity, is favorable and characteristic of natural hydrocenoses. The research results did not reveal the impact of a man-made object on the water flow of reference points.

To add the data to the database and have their reliable processing, the biomonitoring indicators in the reference points of a chemically hazardous human-made object were supplemented with ecoanalytic signs of water,

obtained following the provisions of the GOST R (Russian National Standard) system.

The dependence of the biological indicators of macrophyte communities on the hydrochemical parameters of water ( $C(NH_4^+)$ ,  $C(NO_3^-)$ ,  $C(PO_4^{3-})$ , mg/l) is represented by the following parameters (Table 5).

The results of statistical analysis of the Shannon index dependence on the content of ammonium ions, which was calculated for macrophyte communities, revealed a significant interrelation of the two values. Still, the most substantial is the effect of the increased concentration of ammonium-containing compounds on the increase in  $\alpha$ -diversity (Figure 2). The dominants biomass does not correlate with the concentration of the ions under consideration.

A linear dependence between the content of nitrate ions and the calculated Shannon index has not been revealed. However, an increase in the concentration of nitrate ions causes a regular increase in  $\alpha$ -diversity (Figure 3) and indicators of saprobity index (the equations are given in Table 6)

A high correlation dependence was revealed between the phosphate content in the points under study and the dominant biomass; the dependence of the calculated saprobity index on the concentration of phosphorus-containing compounds is also high (Figure 4).

Thus, a close relationship between biological indicators:  $\alpha$ -diversity, Shannon index, saprobity index was revealed for the concentration of ammonium cation and nitrate ions, the dominant biomass, and saprobity index are related to the concentration of phosphate ions.

The bioindication method, widely used for the diagnostic assessment of aquatic ecosystems, showed the possibility of its use in terms of the recommendations of the Water Framework Directive of the European Union for small European watercourses. In the monitoring area of a chemical hazardous technogenic object of the Russian Federation, semi-aquatic and aquatic vegetation is represented by two classes of 4 orders, 5 unions and 12 associations, which is determined by the latitudinal gradient and Central European conditions for the development of communities. The number of vegetation species that constitute the community remained unchanged for all years of research (from 63 to 74 species), typically river macrophytes dominate, the change of ecological groups is not registered,

the indicators of  $\alpha$ -diversity indicate a considerable diversity of community species. Indicators of the Shannon index for communities testify to the background state of the waters, the absence of the stressful influence of a man-made object, and are similar to the results obtained by other authors (Bornette and Puijalon, 2011; Chappuis *et al.*, 2011; Moore *et al.*, 2012). Geobotanical and ecological characteristics of aquatic macrophyte communities, which were taken into account for hydrobiomonitoring works of semi-aquatic communities are similar to data obtained in the course of European studies.

A slight change in plant production (biomass) was recorded within the statistical significance of differences due to the dynamics of climatic factors affecting the plants production. The Overgrowing of backwaters of small rivers is small, as the flow factor determines the development of a particular biomass of macrophytes and semi-aquatic plants. Consequently, it is recommended to employ ecological and biological indicators and their change for small rivers under the stressful impact of man-made objects during long-term monitoring work: changes in the spatial and species composition of communities, species diversity and ecological groups of species indicate the direct and indirect effects on river waters (Mikulyuk *et al.*, 2011; Steffen *et al.*, 2014).

According to the index of ecological quality of water bodies, recommended by the Water Framework Convention, the biological elements of the rivers of the Non-Black Earth Region of the Russian Federation show a "good" state of the waters.

The ecological state of waters at the reference points of a dangerous man-made object is also determined by hydrochemical indicators, primarily biogenic ions, oxygen availability, saprobity, which indirectly determines the oxygen regime; as well as by hydrophysical indicators: water consumption, continuity of the water flow and others (Ali *et al.*, 2014; Guggenmos *et al.*, 2011).

Long-term observations of the river water saprobity have shown the absence of oxygen starvation, the preservation of significant water flow. A change in the saprobity index from 2.1 to 2.7 (beta-mesosaprobic zone) corresponds to the European indicators and is typical of natural cenoses (Bolpagni *et al.*, 2012; Bornette and Puijalon, 2011; Chappuis *et al.*, 2012, 2011; Ramavandi and Farjadfard, 2014). Thus, hydrobiological and hydrochemical parameters

are interrelated, and aquatic biota directly determines the chemical parameters of the watercourses under study, which has been proven by many studies (Guggenmos *et al.*, 2011).

Technologically determined methods for controlling discharges into water bodies of the area under study have proven high efficiency: the concentrations of biogenic ions in flowing waters correspond to the most stringent indicators of the Russian rationing. The significant connection between the concentration of ammonium-containing compounds, nitrate ions and the increase in the  $\alpha$ -diversity of vegetation is understandable since aquatic species most successfully absorb nitrogen compounds in this form (Ali *et al.*, 2014).

Phosphate ions that serve as markers for dangerous technogenic objects for the disposal of chemical compounds are the limiting indicators for the development of all aquatic biota according to the empirical rule of J. Liebig. The presence of phosphates in river waters determines the growth of biomass (production) and determines the estimated index of saprobity of monitoring objects (Ali *et al.*, 2014; Guggenmos *et al.*, 2011). According to the recommendations of the Water Framework Convention, in determining the environmental quality of water bodies, it is mandatory to take into account hydromorphological parameters, including bottom sediments, determined by phosphoric compounds. Measuring and controlling water ions of biogenic elements are significant for hydrochemical studies (Barinova, 2017a, 2017b; Bolpagni *et al.*, 2012; Ostroumov, 2010). When the excess concentration of biogenic ions in water is revealed, it is possible to recommend the use of macrophyte biomass for ion sorption and phytoremediation of water bodies (Naghipour *et al.*, 2016; Ramavandi and Farjadfard, 2014; Ruiz Jimenez *et al.*, 2011).

#### 4. CONCLUSIONS:

The analysis of the anthropogenic impact on aquatic ecosystems of a chemically hazardous man-made object in the Bryansk region (Russian Federation) using the method of bioindication (which consists in the assessment of species diversity, calculation of the Shannon index and water saprobity index) revealed that the technogenic component of the impact on watercourses is minimal, the state of water bodies corresponds to natural hydrocenoses, the water is clean.

In the monitoring area of a chemical hazardous technogenic object of the Russian Federation, semi-aquatic and aquatic vegetation is represented by two classes of 4 orders, 5 unions and 12 associations, which is determined by the latitudinal gradient and Central European conditions for the development of communities. Indicators of the Shannon index for communities testify to the background state of the waters, the absence of the stressful influence of a man-made object. It is recommended to employ ecological and biological indicators and their change for small rivers under stressful impact of man-made objects during long-term monitoring work: changes in the spatial and species composition of communities, species diversity and ecological groups of species indicate the direct and indirect effects on river waters. Long-term observations of the river water saprobity have shown the absence of oxygen starvation, the preservation of significant water flow. A change in the saprobity index from 2.1 to 2.7 (beta-mesosaprobic zone) corresponds to the European indicators and is typical of natural cenoses.

Thus, the proposed indicators for the organization of hydrobiological monitoring of hazardous man-made objects and their effect on water stand is most preferable. When analyzing the databases on the current and prospective state of any water bodies, it is necessary to take into account additional environmental factors determining the state of aquatic and semi-aquatic communities: first of all, ions of biogenic elements. The presence of these easily migrating ions in water accelerates the development of plant biomass, and also turns out to be a limiting and toxic condition for their development.

When facilities cause the environmental impact for the storage and disposal of chemical weapons, the phosphate ion is recognized as the marker ion in any habitat. Therefore, the detection of an excess amount of this ion in the environment indicates the need for additional monitoring of security systems in the enterprise. Exceeding the maximum permissible concentrations of phosphate ions can be diagnosed in the waters both by biomass growth and by increasing biodiversity, for example, of pleistophytic communities.

## 5. COMPLIANCE WITH ETHICAL STANDARDS:

This article does not contain any studies involving human participants or animals performed by any of the authors.

## 6. FUNDING:

No funding was received.

## 7. CONFLICT OF INTEREST:

The authors report no conflict of interest.

**RESUMO**

A física, como disciplina acadêmica, possui uma linguagem matemática própria e os vetores são seu constituinte indispensável, mesmo no estágio pré-obrigatório. O objetivo desse estudo foi obter um entendimento claro e profundo sobre a percepção da cognição dos alunos sobre as facetas dos vetores que formam a base da mecânica newtoniana. Este estudo fornece não apenas o conhecimento fundamental sobre a cognição de construções fundamentais de vetores entre os alunos, mas também ajuda a melhorar as pedagogias existentes e, eventualmente, levando ao discernimento dos alunos. O autor desenvolveu um Teste de Conhecimento de Conceitos de Vetor Elementar (TKEVC) que foi entregue aos estudantes de engenharia do primeiro semestre que estavam iniciando o curso obrigatório de física de engenharia durante a 1ª semana de aula, antes de qualquer instrução sobre vetores. O TKEVC foi administrado em uma amostra de 476 alunos provenientes de 7 faculdades e universidades de engenharia diferentes da Índia. O resultado obtido com este teste enuncia que apenas 37% dos alunos matriculados no curso de física de engenharia possuem amplo conhecimento de vetores para avançar com tópicos de física, especificamente mecânica, enquanto quase 67% dos estudantes ingressam no curso sem uma compreensão completa dos princípios dos vetores em qualquer aspecto. Essas descobertas têm implicações fortes para as aulas de matemática e física. O pesquisador discutiu as perguntas feitas aos alunos e suas respostas, enfatizando os erros conceituais e metodológicos que eles cometeram. Os resultados têm fortes implicações no ensino de matemática e física de engenharia, no desenvolvimento profissional de professores e na preparação de equipes de professores para instituições de engenharia.

**ABSTRACT**

Physics, as an academic discipline, has its mathematical language, and vectors are its indispensable constituent, even at the pre-mandatory stage. This study aimed to obtain a clear and deep understanding of the perception of students' cognition about the facets of the vectors that form the basis of Newtonian mechanics. This study not only provides fundamental knowledge about the cognition of theoretical vector constructs among students, but also helps to improve existing pedagogies and, eventually, leading to students' discernment. The author developed a Test of Knowledge of Elementary Vector Concepts (TKEVC) that was delivered to engineering students in the first semester who were starting the required engineering physics course during the 1st week of class, before any instruction on vectors. TKEVC was administered to a sample of 476 students from 7 different engineering colleges and universities in India. The result obtained with this test states that only 37% of students enrolled in the engineering physics course have extensive knowledge of vectors to advance physics topics, specifically mechanics, while almost 67% of students enter the course without a complete understanding of the vector principles in any aspect. These findings have substantial implications for math and physics classes. The researcher discussed the questions asked to the students and their answers, emphasizing the conceptual and methodological errors they made. The results have substantial implications for the teaching of engineering mathematics and physics, the professional development of teachers, and the preparation of teams of teachers for engineering institutions.

## 1. INTRODUCTION:

Physics, as an academic discipline, has a mathematical language of its own, and vectors are its indispensable constituent, even at the introductory stage. The elemental conception of Newtonian mechanics is a *force* – a vector. Constraining the motion to one dimension, as is common at the commencing levels of physics education, cannot avoid the reality that the forces are by and large vectors in a plane. They must be added, by way of the rules of vector addition, to ascertain the net force along the axis of motion. Similarly, any treatment and discourse of electric forces or fields, beyond the exclusively descriptive “like charges repel”, must connect with the superposition of vectors (Deventer, 2008).

There has been extensive study, with astronomically large literature, of learners' preconceived ideas and their incorrect excogitation of the concepts of motion and force. Pupil asperities with the superposition of forces and with drawing and making sense of free-body diagrams are long-familiar. Despite anything to the contrary, a good deal of research has riveted on exclusively one-dimensional illustrations where the vector facets of and of kinematic quantities are not instantly apparent. While it is assuredly a fact that learners confront an immediate obstacle with the basic concepts of force, it may well be that a lack of ability to argue accurately, about conceptions of vectors, portray an important, yet less studied, barrier (Barniol & Zavala, 2010, 2012).

The excessively used *Force Concept Inventory* of (Hestenes, Wells, & Swackhamer, 1992) does dig somewhat into learners' instinctive knowing about how two forces combine. Their results suggest that learners oftentimes utilize non-vectorial reasoning. A common delusion is the “dominance principle”, by or through which, the larger of the two forces “wins out” and establishes the motion. Educatees, even after continued exposure to Newtonian mechanics, will, if asked to verbalize their reasoning, often prove such explanations as “Force A overcomes Force B” (J. Aguirre & Erickson, 1984).

The (Hestenes & Wells, 1992)'s *Mechanics Baseline Test* looks in more astuteness at the directional panoramas of the kinematic vectors and the superposition of force vectors. Some of the lowest accounted scores were fathered by those Baseline questions (particularly questions 5, 7, and 19), necessitating the discernment of vector properties (Flores, Kanim, & Kautz, 2004).

(J. M. Aguirre, 1988) looked into the opinions formed beforehand by high-school leaners regarding vector kinematics in projectile motion. He ascertained a large number of faulty preconceived notions, especially concerning the function and implication of the elements of the velocity vector. Perhaps this is not unexpected. After all, vectors are kind of abstract quantities demanding non-intuitive ideas. These results do, be that as it may, indicate that physics didactics needs to set out by giving denotative rumination to pupil conversance with and learning of vectors (Flores-García, Alfaro-Avena, Dena-Ornelas, & González-Quezada, 2008).

Just how much understanding about vectors and their properties do learners who start out the course bring with them into *engineering physics* class? Do all, or most, enter with a working knowledge of vectors? Anecdotal evidence, from casual conversations, indicates that most college-level physics instructors go forward with the hypothesis that pupils have acquired knowledge about vectors somewhere else and simply require a recapitulation to get them up to speed. Is such a premise reasonable and justified?

To find this out, the researcher has developed a *Test of Knowledge of Elementary Vector Concepts* and gave it to the first semester students who are beginning the *engineering physics* course. These were given to students from 7 different engineering colleges and universities of India. The test is reproduced here for other researchers to use if they wish. The elemental judgment reached out from this test enunciates that only a meager 37% of the educatees enrolled for the engineering physics course have ample cognition of vectors to go ahead with physics topics, specifically mechanics, while almost 67% of the students enter with no utile understanding of the principles of vectors in any respect. These findings have strong implications for both mathematics as well as physics instruction. The method used in this study is “*tests of open-ended problems*”.

With a strong and careful design, this study demonstrates a rather dramatic difference, in the generic mathematical context. While on some level, the findings may not come as a surprise to mathematics and physics teachers, it eventually conjure up several questions that are pretty crucial to the pedagogy of vector education: If a learner answers a problem correctly in the *ijk* format, can we still say that she may not have a good command over addition and subtraction of vectors? What do we actually have in mind when

we say we expect from learners to cognize the underpinnings of addition and subtraction of vectors?

If a learner performs haplessly in the arrow format of vectors, with it, can we conclude their pitiful understanding of the fundamental physics, or can we call it the antiquity of the abstractionism that entrammels proper use of vector conceptions? In the teaching of vectors, by and large, the educators teach arrow format to the learners before the *ijk* format—but can we call it truly befitting? Can there be a more spontaneous order, i.e., can the introduction of *ijk* format before arrow format turn out to be a better idea vis-à-vis student's learning? Should there be a definitive pedagogical goal for the learners to efficiently and effectively formulate or explicate fundamental operations of vectors in both arrow and *ijk* formats, or is making students learn only one format good enough?

While few of the queries above distinctly command empirical investigations, which are to be exceedingly focused, the other interrogatives call for judgment that has to be highly professional, and community discussions can be apprised better with such probes. Consequently, to gain insight into responses to all of these queries, the researcher starts by reporting the results and analysis of the test, engineered to transcribe through empirical observations and effectively portray learners' achievement in the cognition of elementary vector operations in mathematical situations in both *ijk* as well as arrow formats.

Researcher's instructional experience with teaching of vectors has led him to conclude that the inadequate cognition exhibited by the learners with regards to ideas inherent in vector algebra presented in graph form demonstrates a peculiarly unmanageable obstruction to their triumph in becoming proficient in concepts inherently belonging to the discipline of physics. Vector ideas and their graphical and geometrical explanations imbue the totality of the curriculum of engineering physics course. Regardless of most learners' earlier encounter to the constructs that are fundamental to vectors, in their classes on maths or in physics which the learned in senior-secondary school (as has been pointed out in various researches), and the excessive stress educators have directed towards those vector constructs in their curriculum transaction, learners' relentless discombobulation about cardinal notions of vectors has befuddled their pedagogical endeavors.

The researcher, therefore, resolved to conduct an organized and directed examination of engineering students' cognition of fundamental conceptions of the addition of vectors, calculation of its magnitude, and determination of its direction during the first few weeks of their *engineering physics* course.

A study by (Randall D Knight, 1995) is reasonably related to this study, and his work colligates an amalgamation of questions from both arrow and *ijk*-format. Non-familiarity with *ijk* notation was showcased by nearly half of the participants. Constructs and calculation on vector algebra dwell at the core of the curriculum on engineering physics, implicit in almost all the themes covered up during compulsory courses at the higher level of engineering education.

As (Randall D Knight, 1995) has accentuated, the vectorial existence of forces, kinematical quantities, and fields commands that learners shall possess a handy and clear cognition of fundamental constructs about vector algebra if they wish to succeed in dominating even the most fundamental level of engineering physics. Knight has made a more or less disguised reference to the astounding inadequacy of documented investigations with regards to learners' cognition of constructs integral to vectors, and his "*Vector Knowledge Test*" allowed for a priceless primary quick look into the assessment of the knowledge of vectors among learners registered for the course on engineering physics, before the commencement of the course.

The current study focusses on dissecting learners' achievement on a test on vectors where the test has no direct bearing to the discipline of physics. The significant issue in this research is that the questions appearing in the test have focalized on the assessment of learners' cognition of the most basic constructs consociated to working with the vectors, like, for example, components and magnitude of vectors. Are there certain vital and even more all-encompassing facets of vectors in general and vector operations in particular that are inadequately expressed and staged, or even curbed, by the representation of vectors in the arrow format? Is it so that the arrow format complements the *ijk* format or contrarily inhibits learner cognition and functioning? This study focusses on gaining an in-depth, clear and deep understanding about the perception of learners' cognition, marked by careful evaluation and judgment on those facets of vectors, which form the base for Newtonian mechanics. Still, here it is done in generic math format by looking into learners' solutions to problems in both arrow

as well as *ijk* formats. This study provides not only the crucial background knowledge about cognition of fundamental vector constructs among learners but also helps to ameliorate the existing pedagogies and eventually to lead to learners' discernment.

## 2. MOTIVATION:

Concepts in introductory physics, mostly covered in an engineering physics course, taught at the undergraduate level in the engineering colleges, are represented by vectors. Consequently, a comprehensive cognition of such physics constructs requires learners to have an effective hold over fundamental vector constructs. Certain specific issues that need special attention include the need for the development of a comprehensive and complete classification of the most frequently occurring errors that students of engineering colleges make. At the same time, they learn about concepts on vector in an engineering physics course, and this, as a consequence, concerns the availableness of MCQ type measurement instruments for testing learners' vector cognition.

Studies done previously on cognition of vector constructs among learners can be agglomerated into three groups: (1) those that didn't use concepts of physics (Barniol & Zavala, 2010, 2012; Deventer, 2008; Flores, Kanim, & Kautz, 2004; Hawkins, Thompson, & Wittmann, 2009; Hawkins, Thompson, Wittmann, Sayre, & Frank, 2010; Hinrichs, 2010; Randall D Knight, 1995; Nguyen & Meltzer, 2003; Wang & Sayre, 2010; Zavala & Barniol, 2010, 2013), (2) those that used concepts of physics (J. Aguirre & Erickson, 1984; J. M. Aguirre, 1988; J. M. Aguirre & Rankin, 1989; Barniol & Zavala, 2010; Barniol, Zavala, & Hinojosa, 2013; Deventer, 2008; Flores *et al.*, 2004; Wang & Sayre, 2010; Zavala & Barniol, 2013), and (3) those that used the mix of both (Barniol & Zavala, 2010; Deventer, 2008; Shaffer & McDermott, 2005; Wang & Sayre, 2010; Zavala & Barniol, 2013). Studies belonging to the first group (Barniol & Zavala, 2009, 2010, 2012; Deventer, 2008; Flores *et al.*, 2004; Hawkins *et al.*, 2009; Hawkins *et al.*, 2010; Hinrichs, 2010; Randall D Knight, 1995; Nguyen & Meltzer, 2003; Wang & Sayre, 2010; Zavala & Barniol, 2010, 2013) have a direct bearing to our inquiry, for they have analyzed learners' cognition of concepts of vectors in problems that had no context to physics.

Six pieces of research from this aggregation (Deventer, 2008; Flores *et al.*, 2004;

Randall D Knight, 1995; Nguyen & Meltzer, 2003; Wang & Sayre, 2010) identified some frequently occurring errors that students from engineering colleges make while they are learning vector constructs. The methods which they used in their investigations were either interviews from individuals or exercising open-ended tests or both.

Researches have done previously (J. M. Aguirre, 1988; J. M. Aguirre & Rankin, 1989; Barniol *et al.*, 2013; Bollen, van Kampen, Baily, Kelly, & De Cock, 2017; Flores-García, Alfaro-Avena, Dena-Ornelas, & González-Quezada, 2008; Flores *et al.*, 2004; Kanim, 1999) and researcher's didactic exposure depicts that the capability of comprehension of prominent themes in the calculus-based physics curriculum at the introductory level demands a firm grip over the fundamentals of vectors.

As being fully aware or cognizant of the essentiality and the requisiteness of laying the groundwork for vector noesis, (Randall D Knight, 1995) and (Nguyen & Meltzer, 2003) engineered tests to appraise the vector cognition, before the vector concept is taught to the engineering graduates in the calculus-based introductory physics course. Both the researches mentioned above established that out of all the learners enrolled for the course on introductory physics, almost 50% of them lacked the requisite understanding about vectors, even though 86% of them affirmed strongly of their familiarity with vectors, right from senior-secondary school (Randall D Knight, 1995).

With regards to learners' previous experience with vectors in senior-secondary schools, research by (Wutchana & Emarat, 2011) brought out that around 32% of students from senior-secondary schools can give right answers to problems on vector addition after they have been taught vectors in the class. In certain educational institutes of higher learning, the math requirement for the fundamental course in physics is Calculus I, and in some institutions, Calculus II is also a requirement, both of which lack treatment on vectors. The course which comes later on in the STEM (science, technology, engineering, and mathematics) course of study is Calculus III, which has time apportionment of approximately 3 weeks (reasonably close to four hours every week) for extended communication on basics of applications of vectors.

For the first time after the completion of school, engineering educatees are given exposure of vectors, in their course on

mechanics, and they are given a maximum of 1 week (average of 2 hours and 30 minutes) on this very pertinent area of study. There have been made numerous attempts to address the issue as mentioned above, and to this front, many research studies have been conducted for the improvement of learners' cognition of vectors in a physics context. A course of study was formulated by (Shaffer & McDermott, 2005) with the idea that was based entirely on research findings and as a consequence they bring forth these two works: "*Tutorials in Introductory Physics*" and "*Physics by Inquiry*" to meliorate learners' cognition of the concepts of kinematics, viewed in terms of vectors.

Flores *et al.*, 2004 and Barniol *et al.*, 2013, researched on implementation of instructional alterations to raise learners' capability to give reasonable justifications with regards to vectors that typify kinematic quantities and forces. Colligated researches (Bollen *et al.*, 2017; Kanim, 1999) also comprises deliberations applicability of vectors to varied themes, including that of electrostatics, electric circuits, and Gauss' law. But then, specific efforts have been made in the improvement of learners' cognition of vectors alone. (Mikula & Heckler, 2013) enquired certain vector problems with varied angular compositions by introducing pedagogy that made use of computers for practicing vector problems (Mikula & Heckler, 2013).

The research by (Flores-García *et al.*, 2008) concludes that learners' inconvenience in cognizing physics constructs is engendered by a sheer deficiency of skills and comprehension with regards to math, specifically vectors. A majority of learners face difficulty with addition and subtraction of vector even when there is no context to physics in the problem. Learners confront complemental asperities in drawing associations with the conceptual framework when certain contexts on the discipline of physics is added to it (Barniol & Zavala, 2014; Barniol *et al.*, 2013; Deventer, 2008).

An excessively limited number of studies have looked into the learner's cognition of subtraction and addition of vectors in the mathematical and/or fundamental physics constructs; the problems asked students in most of the cases employed vector arrow representation (Heckler & Scaife, 2015). (Heckler & Scaife, 2015) researched the learners' cognition of subtraction and addition of vectors in both arrow and algebraic notation (making use of unit vectors).

Quite a lot of investigators have transcribed an array of learner asperities with vector calculations in physical and mathematical environments (Barniol & Zavala, 2010, 2014; Deventer, 2008; Flores *et al.*, 2004; Hawkins *et al.*, 2009; Nguyen & Meltzer, 2003; Shaffer & McDermott, 2005). Nevertheless, in almost all of these researches, only the representations of vectors in their arrow form were reckoned. Although it is common knowledge that arrow representation of vectors is beyond doubt didactically, viscerally, conceptually, and technically effectual and efficacious, yet significant preconceptions are associated with it among the learners. Thus its small range and scope impede its viability in mathematical or logical computations in its capability and competence to individuate few significant attributes of vector algebra and in its acquirement of the representation of vector quantities (e.g., in 3 dimensions or above).

Comparisons could be drawn between the arrow representation and the algebraic representation with their respective attendant advantages and disadvantages making use of vectors in their unit form  $(\hat{i}, \hat{j}, \hat{k})$  in algebraic representation, which is frequently employed in didactics, specifically in the calculus-based introductory physics courses. While investigating learner cognition of vectors in the arrow format, (Nguyen & Meltzer, 2003) ascertained that only about 60%–70% of students with calculus background and 20%–40% of students with algebra background were able to accurately draw the vector sum presented in arrow format on a 2D grid, and only between 60% and 80% of all learners managed to precisely solve problems that asked to determine the direction and magnitude comparison problems related to arrow vectors on a grid.

Vectors represented by (Flores *et al.*, 2004) in arrow format with given lengths and angles found that while calculating the vector sum for determining the net force, a meager 50% of the learners with calculus background managed to solve those problems. One other observation from the study was that only a very few learners could manage to solve those problems that were qualitative and involved finding the difference of vectors in a physical setting (e.g., in acceleration) where the vectors were in arrow format. (Shaffer & McDermott, 2005) also ascertained from his research that many learners were facing handicap with the subtraction of vector in which the vectors were expressed in arrow format on a grid with single dimensions, and learners did slightly better

(65% correct) in mathematics context in comparison to the physical setting of acceleration (where 45% came up with a correct solution).

Contrarily, (Deventer, 2008) determined that learners performed good in the physics (where 50% of the students correctly solved the problem) in comparison to the situation in mathematics (where 20% students found the correct answer) for subtraction in one dimension, reason being learners were inclined towards usage of physics setting to incur the right directions. (Barniol & Zavala, 2010) also established that learners' solution to test problems, where they were to draw the resultant vectors on a grid as arrows, can be marginally sensitive to the problems' context. The solutions given by learners to the problems on addition of vectors can also be reasonably sensitive to the vector's placement of those that are showcased as arrows, such as tail to tip, tail to tail, or separated (Barniol & Zavala, 2010; Hawkins *et al.*, 2009), although no such effectuates were determined when the arrows were placed on a grid (Hawkins *et al.*, 2009).

### 3. REVIEW OF LITERATURE:

Investigation on learners' vector cognition depicts that learners pretty frequently lack the mental faculty required for vector addition, which can eventually lead to learner deterrents (Deventer, 2008; Flores *et al.*, 2004; Randall D Knight, 1995; Nguyen & Meltzer, 2003; Shaffer & McDermott, 2005). Investigators on the usage of varied visual representations of graphical vector addition problems have depicted substantial altercations in learners' method of solving the tasks on vectors. There are many mannerisms for asking learners to perform vector addition or subtraction, graphically. Learners often make use of varied methodologies for vector addition (Deventer, 2008). Head-to-tail and components are the only methodologies described in the fundamental textbooks used for this course (Randall Dewey Knight, 2008).

An extensive body of literature could be found on learners' cognition on the *mechanics* theme (McDermott & Redish, 1999). Mainly, learners' problems with the relationship between velocity and acceleration have been observed in a variety of researches (Trowbridge & McDermott, 1981). Learners' understanding of the relationship between force and motion has also been extensively researched and transcribed (Clement, 1982; Halloun & Hestenes, 1985; Viennot, 1979). Even though the context in most of the cases here

is one-dimensional motion, few are on vector nature of acceleration as well. (Reif & Allen, 1992) inquired from learners enrolled in the fundamental course on physics and to physics faculty members to describe the direction of acceleration for the motion of objects along various paths.

They ascertained that both students (novices) and faculties (experts) found it challenging to answer qualitative questions about the vector nature of acceleration. Even though the answers that they gave to the problems were mostly right, an initial tendency was observed by the experts in the research to make inappropriate arguments and justifications on taking force as the basis rather than justifying solutions to the problems solely on the grounds of kinematics.

Shaffer (1993), in his research, found that only 6 out of a total of 48 graduate students managed to showcase the approximate direction of acceleration for all positions and the most frequently occurring errors committed were the inclusion of either only the radial or only the tangential components of the acceleration. (Randall D Knight, 1995) in his research found that only about 33% of the students "have sufficient vector knowledge to proceed with mechanics." (Nguyen & Meltzer, 2003) in their research concluded that just over 25% of the students finishing a calculus-based mechanics course and close to 50% completing the algebra-based course could somehow manage to add vectors in two dimensions.

In the inquiry of learner cognition of vectors in electrostatics, (Kanim, 1999) ascertained that most of the learners faced immaculate trouble in thinking coherently and logically about the net electric forces and fields from collections of point sources. That additional inconveniences are brought in when attempting to give a rational justification about the field and force vectors from continuous charge distributions. It has been deduced from nationally administered tests that problems that involve force or acceleration as vector quantities are not easy for most of the learners. For instance, on the Mechanics Baseline Test (Hestenes & Wells, 1992), one problem asks learners to draw a comparison between the magnitudes of four force vectors, acting on an object that is moving at a constant speed.

Another problem demands learners to determine the direction of acceleration for a block when it is at the lowest point on a curved ramp. Learners showcased poor performance on these problems after the standard instruction. About

thirty-six percent managed to solve the problem on force correctly, and a meager eighteen percent solved the problem on acceleration accurately. Contrarily, the Force Concept Inventory (Hestenes *et al.*, 1992) does not test for the cognition of vectors: On the revision of the test, the only question that required an understanding of vectors was removed from it. The aforementioned probes accentuate the essentiality of conceptual cognition of vectors for learners to immerse themselves in engineering physics course efficaciously.

(Kanim, 1999) researched learners' cognition of constructs of a vector in the context of electrical forces and fields. (J. M. Aguirre, 1988) and (J. M. Aguirre & Rankin, 1989) examined learners' conception concerning vector kinematics, their inquiry was cantered around the interrelationships among acceleration, velocity, and force instead of vectors properties intrinsically. (Ortiz, 2002) researched on pupil's inconvenience in cognizing fundamental vector operations commonly made use of in the beginning of physics courses.

## 4. MATERIALS AND METHODS:

### 4.1. Construction and goal of the “test of knowledge of elementary vector concepts”

The goal of the *Test of Knowledge of Elementary Vector Concepts* is neither to judge whether the learners are eloquent in vector mathematics nor that they can effectively utilize vectors in a refined way. Instead, it is to see if they have the minimalistic knowledge and skill required to work with vectors that could eventually make it possible for them to go forward with the study of qualitative and quantitative Newtonian mechanics. The *Test of Knowledge of Elementary Vector Concepts*, reproduced as an appendix to this article, is thus excogitated to assess pupils' knowledge of the most basic level of vector properties and operations. It probes a learners' ability to:

1. Identify and make appropriate use of the components of a vector,
2. Determine the vector's magnitude and direction,
3. Ascertain vector sum using graphs, and
4. Find the sum of two vectors using components.

These are essential skills for success in basic

Newtonian mechanics. Also, the test looks, for completeness, at student ability with the more advanced capabilities of vector multiplication.

The test has two levels. It first asks students if they are familiar with a given vector topic. Those answering in affirmative are the asked one or more fundamental problems. The problems assess whether or not the student's self-rating is correct. There are a total of ten *questions* and ten *problems*. To minimize guessing, students are instructed to leave blank any issues they think they do not know how to work. The second question, asking students if they have studied vectors previously, instructs those answering “NO” to skip the rest of the test. This test structure, with the accompanying instructions, allows students to be classified as:

1. Having no previous experience with a particular topic (if they answer “NO” and leave the problem blank),
2. Having previous experience but having no working knowledge (if they answer “YES” but work the problem wrong), or
3. Having previous experience and working knowledge (if they answer “YES” and work the problem correctly).

The *Test of Knowledge of Elementary Vector Concepts* was given to all the first semester students (N = 476) enrolled in mid-July 2019 where they have a compulsory *engineering physics* course. Approvals were obtained from 11 local ethics committees. To shield the identity of the participants as well as of the engineering institutions, pseudonyms were rendered to them. Samples were drawn from seven engineering colleges and universities in India. It was during the 1<sup>st</sup> week of class, before any instruction about vectors, the test was administered. The students in the class were predominantly computer engineering majors, with sizable admixture of biotechnology, mechanical, electrical, civil, and architecture students.

All the students had cleared JEE Mains (some even had cleared JEE Advanced). Altogether, the students were above average in comparison to students taking up *engineering physics* classes at other engineering colleges and universities of India. Their performance on the *Test of Knowledge of Elementary Vector Concepts* is expected to be typical of engineering students beginning their course at most of the top-ranked engineering colleges and universities of the country.

## 5. RESULTS AND DISCUSSION:

Answer to the first question revealed that 91% of the students were taking the course for the first time while 9% (41 students) were repeating the course. It will be useful to break out the responses for this subgroup to see what light it sheds on why they did not succeed in passing the course previously.

Answer to question two establishes that 96%, i.e., 456 students beginning the *engineering physics* course have studied vectors before. This includes, of course, 100% of the students who were repeating the course as well as 87% of the new students. Their previous exposure to vectors was roughly evenly divided between math courses and prior physics courses, with a large fraction having seen vectors in both places. The response to this question seems to confirm the common assumption that these are not entirely new ideas for most students.

Table 1 presents the complete results of the *Test of Knowledge of Elementary Vector Concepts*. Responses as percentages are shown for three groups:

- i. Students new to the course *and* who have studied vectors before ( $N_1=415$ )
- ii. Students repeating the *engineering physics* course ( $N_2=41$ )
- iii. All the students present in all the classes from 7 institutions who took part in the study ( $N_3=476$ )

Group I examines to what extent students who have studied vectors before can recall and use that knowledge. Group II provides information as to whether a lack of specific skills, in this case, vector mathematics, is a factor for students who fail to complete the course.

"Questions" and "Problems" from the test are indicated in the left column as "Q" or "P". Since students were instructed to leave those questions blank, which they were not able to answer, rather than to guess, "blank" answers are tabulated separately from "wrong" answers. Here "wrong" means that the student provided an incorrect answer. The primary comparison to make with the Table 1 data is between the percentage of students answering "Yes, I know that," and the rate who correctly worked a fundamental problem testing their knowledge of that concept. Except for Problems 2, 5, and 6, the percentage of learners giving the accurate solution to the problems is

invariably less (often much less) than the percentage asserting that they possessed such knowledge.

Ideally, students answering "Yes" to a self-assessment question would then proceed to attempt the subsequent problem or problems while those answering "No" would leave it blank. In this case, the percentage of blank responses to the problem would equal the percentage responding "No" to the question. Sometimes, though, a student would answer "No" to the question and then proceed to attempt the problem anyway – occasionally getting the answer correct! However, the number of students who knew more than they thought was significantly fewer than the number who knew less than they thought.

Question 3 asks students to define a vector in their own words. Any answer mentioning *magnitude* and *direction*, or something equivalent (e.g., "length" rather than "magnitude"), was counted as correct. Answers that said at least something relevant to vectors were counted as partially correct. By far, the most common partially correct response equated vectors with specific physical quantities (e.g., "A vector is a force"). Even with very generous scoring, only 44% of the class provides an adequate definition, while 29% either left it blank or provided an answer having no connection at all to vectors. It is worth noting that many of the responses counted as fully correct seemed to view vectors as something used only in physics rather than as mathematical objects.

Questions 4 and 5 and Problems 1 and 2 are concerned with vector components. Two common errors of problem 1 were to omit the minus sign or to include the unit vector  $\hat{j}$  (i.e.,  $-\frac{21}{22\pi}\hat{j}$ ) as part of the answer. The following error, curiously, was widespread among students repeating the course. Students making these errors fail to realize that the component of a vector is simply a scalar number, possibly signed. In Problem 2, answers are given as "(1, 3, 2)" were accepted, since this is how students often learn about vectors in math classes, but the reasonably common response of " $x + 3y + 2z$ " was not accepted as correct.

Question 6, together with Problems 3 and 4 asks whether students can express a vector in direction and magnitude terms. The percentage of learners who found the magnitude correctly was significantly more than the percentage of learners who found the directions accurately, and these are shown in Table I as "Magnitude OK." Even though 3-4-5 triangles were used, symbolic

answers were accepted since not all students had scientific calculators.

Problem 5, on graphical vector addition, had more wrong attempts than any other problem from P1 through P10. The most common incorrect response, by far, was to draw a vector from the tip of  $\vec{E}$  to the tip of  $\vec{F}$ . Pupils were found making use of the bisector method if they arranged the vectors tail-to-tail and drew the resulting vector between them. Educatees who made use of the bisector method, in particular, showed carelessness with regards to the magnitude of the resultant vector. The success rate of Problem 6, algebraic vector addition, was significantly higher. One possible explanation is suggested by looking at those students who answered Problem 2, when asked to write a vector in a component form, as (1, 3, 2). This group did significantly better than the sample average on Problems 2 and 6, dealing with components, but relatively poor than the sample average on Problem 5, i.e., graphical addition. While the number in this group (N=24) is too small to draw definite conclusions, their responses indicate that some fraction of the learners have learned about vectors exclusively as pairs of numbers, devoid of any geometric content. Together, Problems 1 through 6 covers the basic vector properties and operational need for Newtonian mechanics. The average score for these six problems are shown at the bottom of Table 1. The sample average is only 36% correct responses. The final two questions and four problems are concerned with vector multiplication. These were for informational purposes since vector multiplication is not a prerequisite to a general understanding of mechanics. As anticipated, only a small fraction of students reported reasonable competence with vector multiplication, and even fewer (< 10%) could work a simple problem.

### 5.1. Educational implications

The findings from the *Test of Knowledge of Elementary Vector Concepts* are presented in Table 2. This table showcases the various abilities of students to use vectors (in approximate percentage) drawn from the first semester of engineering courses which have taken up *engineering physics* course. Taken as a whole, the *Test of Knowledge of Elementary Vector Concepts* suggests that roughly 20% of the class is sufficiently skilled with vectors, read the texts of the problem and solve typical problems without further practice. While this group still needs to acquire specific knowledge, such as finding vector directions, they can likely learn these skills with

minimal instruction since their knowledge base is good. Roughly 12% of the students can work on the path of vectors as well. This means that this 12 % of students, i.e., a total of only 57 students out of 476 students enrolled for the course, are ready in the most real sense for the course, and the rest are not. Only these 12% of the entire sample have awareness about vector properties and are very much likely to incorporate vectors into their “working knowledge” of mathematics without additional instruction and practice.

This table presents the approximative percentage of learners who have taken an engineering physics course in their 1<sup>st</sup> semester of engineering program against the skill sets indicated. This leaves a full 88% of the students enrolled for this course in their engineering programs with no utile noesis of vectors in any respect. This does not, in and of itself, invalidate the assumption that most students have seen vectors in previous classes. Question 2 indicates that 96% of students had, indeed, “studied” vectors at some prior time. Further, high percentages of students gave affirmative self-assessments that they “knew” most of these basic ideas. The results of the *Test of Knowledge of Elementary Vector Concepts*, however, indicate otherwise. Since, as noted, the sample students enrolled for this course are relatively typical of a charitable institution, it is expected that similar results would be found at most other top engineering colleges and universities.

The responses of those students repeating the course, after withdrawing or failing on a prior try, are especially interesting. Their knowledge, after a full semester of college-level engineering physics, is only slightly better than that of new students who indicated a previous study of vectors. Only 43% of this group could correctly add two vectors graphically, although 86% thought they knew how, and only 45% gave a satisfactory definition of a vector. Combining force vectors, whether for free-body diagrams or for conceptual reasoning, is an essential skill for success in Newtonian mechanics. Although cause and effect are difficult to disentangle, the results suggest that a major reason for the failure of these students was their lack of understanding of vectors.

Like many other aspects of elementary physics, vectors seem “obvious” to those of us who have used them for many years. They are by no means evident to students, as these results show. Since the previous study, for most, has produced little usable knowledge, it is unlikely that a few quick sketches on the board, with

expressions of “This is how you do it,” will suffice as instruction. From the earliest stages, understanding vectors are essential for progress in physics, so it behooves those who belong to the physics education community to think about how better to incorporate vectors into introductory physics.

It is tempting to think that the physics education community can let the mathematics department do this for them. Unfortunately, standard calculus texts do not treat vectors until shortly before multivariate calculus is introduced. At Indian universities and colleges, students do not see vectors in their “Engineering Mathematics” course until near the end of the first year. Providing learners with the necessary instruction is a task physics teachers themselves will have to take.

Arons & Holbrow, 1990, have discussed student difficulties with learning about vectors noting that “Many students would benefit from more exercises and drill in graphical handling of vectors than are usually available in texts”. That extended, on-going practice is needed seems apparent from the shallow scores of students who had studied vectors before but retained little. Spending one day on the standard vector chapter, found in mostly all texts, followed by one homework assignment is probably not sufficient for most students. There exists a variety of options for dealing with this problem. For example:

1. Instructors should make *explicit* mention of vector properties for several weeks as they proceed through projectile motion, forces, free-body diagrams, and so on. Don't assume that students understand after one day; much reinforcement will be necessary.
2. Additional homework problems on vectors should be assigned for several weeks. Students need to keep practicing vector math and reasoning *after* they get feedback from their first vector homework.
3. A laboratory period early in the course could be devoted to a vector tutorial. Students would receive a hand-out containing a variety of problems on which to practice and then would get immediate feedback from their instructor. Working with groups would encourage discussion and active participation. This could be followed, the following week, with a force

table or similar experiment in which students measure and add non-collinear forces.

4. Basic practice with vector math could be provided via computer-aided instruction. An endless variety of problems could be provided, with hints when needed and immediate feedback. Since such practice deals only with the mechanics of vector manipulation, it would need to be supplemented with a more general discussion of what vectors are and how they are recognized and used in physics.

## 6. CONCLUSIONS:

Irrespective of the method(s) put to use, pupils who take up the *engineering physics* course, need at the very beginning an explicit instruction, leaving nothing to opinions formed beforehand by the educators about their educatees, in and practice with the application of vectors. A bulk of learners join the course with no working knowledge of vectors. These students are not likely to be successful with the basic principles of Newtonian mechanics, such as the superposition of forces until their ability to reason with the use of vectors has been established. The researcher hopes that an investigation of students' cognition of vectors to the general understanding of mechanics can render direction or helpful suggestions toward the designing of course modifications that will eventually beef up learners' perspective of physics as a logically ordered branch of knowledge, instead of the aggregation of discrete facts, where the vector is mere a part. There is a need for heightening learners' instinctual application of vectors in answering varied questions in the physics context. Nonetheless, researchers here also accentuate that improving learners' cognition of vectors continues to be a significant challenge.

## 7. FUTURE RESEARCH:

Although many tests with their unique emphasis that integrate the recommendations, implications, and suggestions of investigators engaged in study of physics education (Beichner, 1994; Ding, Chabay, Sherwood, & Beichner, 2006; Paula V Engelhardt, 2009) have been developed (Aslanides & Savage, 2013; Beichner, 1994; Paula Vetter Engelhardt & Beichner, 2004; Hestenes *et al.*, 1992; Maloney, O'Kuma, Hieggelke, & Van Heuvelen, 2001; McKagan, Perkins, & Wieman, 2010; Singh & Rosengrant, 2003; Thornton & Sokoloff, 1998; Tongchai,

Sharma, Johnston, Arayathanitkul, & Soankwan, 2009; Wuttirom, Sharma, Johnston, Chitaree, & Soankwan, 2009), one that assessed learners' cognition of concepts on vector algebra holistically is yet to be developed and consequently there arise the need for a large-scale longitudinal study at the level involving multiple universities from several countries that would dissect learners' cognition of concepts inherently enshrined in vectors, after finishing their introductory physics courses, is a pressing requirement.

## 8. CONFLICT OF INTEREST:

The author reported no potential conflict of interest in conducting this research.

## APPENDIX: TEST OF KNOWLEDGE OF ELEMENTARY VECTOR CONCEPTS

Question 1: Is this the first time you are taking this course, i.e., a course on *engineering physics*?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No, I am repeating the course.

Question 2: Have you studied vectors before?

\_\_\_\_\_ No. STOP! Do not answer any more questions on this test.

\_\_\_\_\_ Yes. It was in:

Senior Secondary School Math \_\_\_\_\_

Senior Secondary School Physics \_\_\_\_\_

College Maths \_\_\_\_\_

College Physics \_\_\_\_\_

Question 3: Define Vector.

Question 4: Do you know how to write a vector in terms of its components?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

Question 5: Are you familiar with the unit vectors  $\hat{i}$ ,  $\hat{j}$ , and  $\hat{k}$ ?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

**Instructions:** For the problems that follow, answer only those that you can. If you don't know how to solve the problem, leave a blank. Don't make wild guesses.

Problem 1: What is the y-component of the vector:

$$\vec{A} = -\frac{3}{\pi} \frac{(\hat{i} + 7\hat{j} - 9\hat{k})}{22} ?$$

Problem 2: Write the vector  $\overrightarrow{OP}$ , from the adjacent figure, in component form.

Question 6: Do you know how to express a vector as a magnitude and angle?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

Problem 3: Write the vector  $\vec{C}$ , shown in the figure, as a magnitude and an angle.

Problem 4: What is the magnitude and angle of the vector :

$$\vec{R} = -\frac{3}{4}\hat{i} - \frac{\pi j}{\frac{9}{8}} ?$$

Question 7: Do you know how to add two vectors graphically?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

Problem 5: Working directly on this figure, add vectors  $\vec{E}$  and  $\vec{F}$  graphically.

Question 8: Do you know how to add two vectors algebraically?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

Problem 6: Given  $\vec{P} = -\frac{3\pi}{29}\hat{i} + \frac{8}{91}\hat{j}$  and  $\vec{Q} = \frac{-34\hat{i} - \frac{5}{3}\hat{j} - 33\pi\hat{k}}{\pi/6}$ ,

what is the sum  $\vec{P} + \vec{Q}$  ?

Question 9: Do you know how to evaluate the “dot product” (or “scalar product”) of two vectors?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

Problem 7: Given  $\vec{P} = -\frac{3\pi}{29}\hat{i} + \frac{8}{91}\hat{j}$  and  $\vec{Q} = \frac{-34\hat{i} - \frac{5}{3}\hat{j} - 33\pi\hat{k}}{\pi/6}$ ,

what is the dot product  $\vec{P} \cdot \vec{Q}$  ?

Problem 8: What is the dot product  $\vec{U} \cdot \vec{V}$  of the vectors  $\vec{U}$  and  $\vec{V}$  shown here?

Question 10: Do you know how to evaluate the “cross product” of two vectors?

\_\_\_\_\_ Yes.

\_\_\_\_\_ No.

Problem 9: What is the cross product  $\vec{U} \times \vec{V}$  for the two vectors shown here?

Problem 10: Given  $\vec{U} = -\frac{3\pi}{29}\hat{i} + \frac{8}{91}\hat{j} + 19\hat{k}$  and  $\vec{V} = \frac{-34\hat{i} - \frac{5}{3}\hat{j} - 33\pi\hat{k}}{\pi/6}$ ,

what is the cross product  $\vec{U} \times \vec{V}$  ?

#### RESUMO

O queixo afeta a estética facial e a harmonia entre as vistas frontal e lateral, sendo uma das estruturas anatômicas mais importantes do terço inferior da face. O objetivo da osteotomia do queixo é a harmonização do perfil facial, equilibrando o tamanho e a forma do terço inferior da face. Assume-se que a cirurgia isolada de genioplastia melhorará o espaço das vias aéreas faríngeas (PAS), promovendo alterações musculares, especificamente puxando o osso hióide para frente e descomprimindo a região da hipofaringe. Dois pacientes sem síndrome da apneia obstrutiva do sono (SAOS) foram submetidos à osteotomia isolada do queixo para fins estéticos. O movimento para frente do queixo pelo ponto Pg foi de 7 mm em um caso e 11 mm no outro. Eles foram avaliados por tomografia computadorizada de feixe cônico no pré e pós-operatório. O espaço das vias aéreas superiores foi subdividido em espaços retropalatais e retroglossais. Depois disso, o espaço das vias aéreas superiores foi analisado através dos seguintes critérios: 1) superfícies tridimensionais, de alta altitude e seção transversal; 2) alterações transversais e anteroposteriores do diâmetro. A genioplastia segmentar isolada foi utilizada após um planejamento virtual preciso e resultou em um aumento do espaço das vias aéreas faríngeas apenas em um caso. Houve correlação relevante entre a alteração vertical e horizontal do queixo e a hipofaringe. Houve uma média de um aumento de 1,6 vezes no volume total do espaço aéreo superior. O espaço retroglossal foi aumentado em 1,5 vezes. Em outro caso, não houve correlação relevante entre a alteração vertical e horizontal do queixo e a PAS. A osteotomia segmentar isolada do queixo fornece um resultado estético previsível na correção de diferentes deformidades anteriores da mandíbula e pode resultar em aumento do volume e alteração morfológica das vias aéreas. Mais estudos devem ser feitos para avaliar o efeito da genioplastia segmentar isolada no espaço das vias aéreas faríngeas.

**Palavras-chave:** Cirurgia de genioplastia, osteotomia segmentar do queixo, deformidade facial, espaço das vias aéreas faríngeas (PAS), síndrome da apneia obstrutiva do sono (SAOS) .

#### ABSTRACT

The chin affects facial esthetics and the harmony between frontal and lateral views and is one of the most important anatomic structures of the lower third of the face. Chin osteotomy is aimed at ensuring the harmonization of the facial profile by balancing the size and form of the lower third of the face. It is assumed that the isolated genioplasty surgery will improve the pharyngeal airway space (PAS) by promoting muscle changes, specifically by pulling forward the hyoid bone and decompressing the hypopharynx region. Two patients without obstructive sleep apnea syndrome (OSAS) underwent isolated chin osteotomy for esthetic purposes. Forward movement of the chin by the Pg point was 7 mm in one case and 11 mm in another case. They were evaluated by preoperative and postoperative cone-beam computed tomography scans. The upper airway space was subdivided into retropalatal and retroglossal spaces. After this, the upper airway space was analyzed through the following criteria: 1) three-dimensional, high-altitude, cross-sectional surfaces; 2) transverse and anteroposterior diameter changes. Isolated segmental genioplasty was used after precise virtual planning and resulted in the PAS increase only in one case. There was a relevant correlation between the vertical and horizontal chin change and the hypopharynx. There was an average of a 1.6-fold increase in the total volume of the upper airway space. The retroglossal space was increased 1.5-fold. In another case, there was no relevant correlation between the vertical and horizontal chin change and the PAS. Isolated segmental chin osteotomy provides predictable esthetic results in the correction of different mandible anterior deformities and may contribute to an increased volume and a morphologic airway change. Further studies should be conducted to

evaluate the effect of isolated segmental genioplasty on the pharyngeal airway space.

**Keywords:** Genioplasty surgery, segmental chin osteotomy, facial deformity, pharyngeal airway space (PAS), obstructive sleep apnea syndrome (OSAS).

## 1. INTRODUCTION:

The chin is one of the most important units of facial structures responsible for common facial appearance and esthetics. Chin osteotomy is an orthognathic surgical procedure that is usually performed in addition to bilateral sagittal split osteotomy of the mandible and sometimes as an isolated surgical procedure (Haggerty and Laughlin, 2015; Santagata *et al.*, 2015; Kawamata *et al.*, 2000). The aim of chin osteotomy is the harmonization of the facial profile by balancing the size and form of the lower third of the face.

Cone-beam computed tomography (CBCT) with a 3-dimensional cephalometric and airway analysis is routinely used as an important and necessary tool for analyzing the skeletal and dental relationships, as well as identifying and quantifying the site of obstruction (Chen *et al.*, 2007; Hwang *et al.*, 2010; Eggensperger *et al.*, 2005).

As it is known, the upper airway volume is directly dependent on the size and relative positions of the maxillofacial skeletal structures and on the dental arches, both relative to one another and the cranial base (Tan *et al.*, 2017; Guven *et al.*, 2005; Pae *et al.*, 2008). Thus, the average rate of the minimum cross-sectional area of the upper airway is 149.3 mm<sup>2</sup> in normal adults. However, the upper airway size of under 52 mm<sup>2</sup> in adults is associated with sleep apnea (Bhattacharyya *et al.*, 2000; Schendel *et al.*, 2012; Al-Moraissi *et al.*, 2015; Choi *et al.*, 2014).

An increase in the airway size associated with maxillomandibular advancement surgery and orthognathic surgery is well studied (Zucconi *et al.*, 1999; Schendel *et al.*, 2011; Abramson *et al.*, 2011; Fairburn *et al.*, 2007; Brown *et al.*, 2013; Pirklbauer *et al.*, 2011; Boyd *et al.*, 2013; Zucconi *et al.*, 1999). However, 3-dimensional morphologic, volumetric, height, cross-sectional surface areas and diameter changes of the pharyngeal airway space (PAS) after isolated segmental chin osteotomy (SCO) are not well understood.

Therefore, this study aimed to prove the assumption that the isolated genioplasty surgery will improve the pharyngeal airway space by promoting muscle changes, specifically by pulling

forward the hyoid bone and decompressing the hypopharynx region.

## 2. MATERIALS AND METHODS:

Two patients without obstructive sleep apnea syndrome (OSAS) underwent isolated segmental chin osteotomy to improve facial esthetics (Logvynenko and Dakhno, 2018). Informed consent in which all benefits, risks, alternatives, and limitations to the technique are considered was obtained before the operations. All methods were performed following the relevant guidelines and regulations of our hospital. The effect of this surgery on the increase of the pharyngeal airway space was studied based on these cases. The hypothesis of the present study was the statement that the advancements of the chin segment – including the mental spines and the genioglossus muscle – will cause a significant increase in the pharyngeal airway volume.

Both patients were evaluated based on preoperative and postoperative CBCT scans, which were done by using the Gendex CB-500 by iCat scanner (Imaging Sciences International, Hatfield, PA) with a low-dose protocol. The procedure was done in Natural Head Position (NHP) while the patients were seated.

The DICOM data were then 3D reconstructed and analyzed using the SIMPLANT O&O software (Materialise N.V., Belgium). The analysis of the upper airway changes was performed by comparing preoperative and postoperative images. The upper airway space was identified and measured from the level of the posterior nasal spine to the lower edge of the hyoid bone (Figure 1).

According to the demands of the study, the upper airway space was subdivided into (1) the retropalatal space (covering the area from the level of the posterior nasal spine at one point and continuing to the lower edge of the soft palate at another point), and (2) the retroglottal space (covering the area from the lower edge of the soft palate and continuing to the hyoid bone, as depicted in Figure 2).

The upper airway was analyzed for a volumetric, cross-sectional surface area, as well as transverse and anteroposterior size changes.

The next step was virtual surgical planning: interactive chin cutting and bony segment repositioning to optimize esthetic results (Figure 3, 4).

The initial 3D model and the surgical simulation 3D model of the skull were printed. An intraoperative positioning surgical guide was designed using Mimics software by Materialise NV. and printed using a 3D printer (Objet30 OrthoDesk jets, Stratasys Ltd. Nasdaq: SSYS) according to the 3D plan of segmental chin osteotomy for proper positioning of the fragments.

In the first case, the patient requested chin augmentation. She had had a bad experience with a silicone implant because of the asymmetric positioning and contouring of the implant margins, which is why it had been removed. So her expectations from chin osteotomy were high, and thorough 3D planning was required. Two pieces' segmental chin osteotomy was planned with the forward movement up to 6,66 mm and the rotation of the fragments providing more V-shape form of the chin and control of the contour of the mandible (Figure 5).

After the 3D project was approved by the patient, the 3D model of the skull was printed, and the surgical guide was designed and printed to help accurately transfer treatment plans to the operating room and to position the fragments properly. Titanium plates were curved and adapted to the fixation fragments on the 3D model.

The second case was represented by the patient with retrusive facial appearance, lip incompetence, and increased lower third of the face. As the patient rejected bimaxillary orthognathic surgery, genioplasty was proposed as an alternative plan (Figure 6).

To improve the facial profile, it was necessary to move Gn forward up to 11 mm and upward up to 5 mm. In reality, such movement is impossible if planned as sliding osteotomy for this patient, because the chin bone fragment will lose any contact with the mandible. Moreover, hanging it by plates has a lot of risks – resorption, loss of stability, steps of the contour of the mandible. That is why a decision was made in favor of segmental chin osteotomy. The combination of forward and upward movements with counterclockwise rotation in the sagittal plane, the divergence of the fragments, and the control of the contour of the mandible give us the possibility to achieve a favorable Gn position and

a fine V-shape form of the chin. The patient was presented with the visualization of the complexity of achieving the desired result.

In the operating room, under general anesthesia, osteotomies were done by piezotome. Minimal bone loss and precise cutting were admitted. In all cases, the attached lingual periosteum on all bone fragments was retained to preserve blood supply. The SCO procedure preserves the attachment of the anterior belly of the digastric muscle. SCO capturing the genial tubercle and the genioglossal muscle was precisely performed, and then the bone parts of the chin were fixed to the surgical guide by screws. After all bone parts were accurately positioned, they were fixed with rigid plates and screws to one another. The final bone gaps were filled by cortical bone particles of xenogenous origin.

Postoperative CBCT scans, 3D cephalometry, and upper airway analyses were re-performed postoperatively in 6 months and 2 years (Figure 7).

CBCT scans were done in Natural Head Position (NHP) on the same Gendex CB-500 by iCat scanner by the same operator while the patient was seated. This type of examination shows the form and size of airways only when the patient is awake and seated steadily upright. One should note that when the patient is asleep and/or lying on the back airways, the soft tissues are more relaxed and can narrow the airways and obstruct the airflow.

The next step was to analyze the DICOM data by using the SIMPLANT O&O software (Materialise N.V., Belgium). Then the upper airway changes were evaluated by comparing preoperative and postoperative scans.

### 3. RESULTS AND DISCUSSION:

This study involved two patients without obstructive sleep apnea syndrome who underwent isolated segmental chin osteotomy. Isolated segmental genioplasty was used after precise virtual planning and resulted in an increased pharyngeal airway space only in one case. The chin segment was moved 11.77 mm in the first case and 8.54 mm in the second (Figures 8 and 9). There were no major complications.

In the first case, the volume of the upper airway increased significantly by 59.5% as a result of chin advancement. The retroglossal volume increased more than the retropalatal volume. The area of the smallest airway (choke

point) before surgery was 84.6 mm<sup>2</sup>, and after surgery – 202,1 mm<sup>2</sup>. Correction to the norm of the airway is confirmed by obvious changes in the PAS shape from a funnel to a tube-like one, as shown in the figures. A closer examination of the surface-area slices reveals that the anteroposterior dimension increased more than the transverse dimension in terms of millimetric changes (Figure 10).

The hyoid bone, a predictor of airway obstruction, changed and moved more superiorly and closer to the mandible. The hyoid to mandibular plane measurement decreased after surgery, indicating an elevation of the hyoid.

In the second case, the upper airway space increased only by 3.5 % in the total volume (Figure 11), which is considered not a clinically significant change. This result might be associated with a different level of osteotomy of the lingual cortical plate of the chin, and fewer muscle attachments were moved forward with the chin fragment (Figure 12). However, more clinical cases are required to be certain about this. All measures are compacted in Tables 1-3.

Obstructive sleep apnea syndrome is a condition having many factors. Its diagnostics and the way of medical treatment have to be personalized and individually differentiated. The multidisciplinary management is also essential. The specific diagnosis and the plan of treatment is usually formed after both comprehensive medical plus dental history analysis and scrupulous mediocal examination being held analysis and examination. Adjunctive diagnostic studies such as CBCT imaging for airway analysis, fiberoptic nasopharyngoscopy, polysomnography, and 3-dimensional cephalometrics are included in the workup. Obstructive sleep apnea is correlated with an upper airway anatomic obstruction. The correction of this anatomic obstruction by surgery is an effective way of treatment. Therefore, it has to be definitive medical decision due to the medical indications and has to be considered as appropriate for patients with mild, moderate, or severe OSAS (Pirklbauer *et al.*, 2011).

As it is known, maxillomandibular advancement surgery with a combination of forward and upward movements with counterclockwise rotation in the sagittal plane plays an important role in OSAS correction. Thus, in a recent study, Boyd *et al.* stated that maxillomandibular advancement should be the surgical option of choice for patients with moderate or greater OSAS (Boyd *et al.*, 2013).

Today, the widespread use of CBCT scans and the development of automated airway analysis systems allow the surgeon to have more refinement in surgical planning since the exact sites and the extent of the obstruction can be better visualized. Thus, surgery can be tailored for each patient. The upper airway can be divided into three anatomic sections for evaluation and treatment.

The first level is the nose. Each internal nose deformation immediately affects the airflow. Deformities or collapses of the alar cartilage will cause airflow reduction at the external nasal valve. Septal deviations or septal spur can obstruct the nose and cause airflow turbulence. The enlargement of turbinates may also cause nasal obstructions and reduce the airflow, so surgical reduction might be indicated. A narrow nasal floor may (anatomically) affect adversely the airflow of the nose. Since the nasal floor is the hard palate, maxillary constriction and crossbites must be considered as causative factors. For such children patients, rapid palatal expanders can be applied. For adult patients, surgically assisted rapid palatal expansion is a choice. It should also be noted that maxilla restriction will affect the tongue position and cause a decrease in the pharyngeal airway space.

The second level includes the retropalatal area and the lateral pharyngeal walls. In the adolescent age, the most widespread reason for airway obstruction is lymphoid hyperplasia with the enlargement of the adenoids and tonsils. This is reported to be the cause of airway obstruction 60% of the time and provokes mouth breathing (Zucconi *et al.*, 1999). The obstruction removal by applying appropriate surgery methods is the most effective solution. However, tonsillectomy and/or adenoidectomy alone do not resolve the obstruction for 27% of these patients. Micrognathia, retrusive maxilla, open bite and/or crossbite, and a Class III malocclusion will also result in the decreased retropalatal airway space. Airway problems can also be observed after cleft palate surgery. Adult people having a long palate may suffer from snoring and progressive thickening of the palatal tissues compounding the airway obstruction.

The third level includes the retroglossal area and the tongue. The retroglossal area is mostly influenced by the position of the mandible and the tongue. Mandibular retrognathia may lead to the base of the tongue to the position posteriorly during sleep and obstruct the airflow. Mandibular retrusion can also cause obstructions

at the palatal level. These deformities can be evaluated with CBCT scans and 3-dimensional cephalometric and 3-dimensional airway analyses.

The tongue, mandible, and hyoid system are functionally composed of two bony components, the hyoid and mandible, and one muscle component, the tongue. The tongue, mandible, and hyoid system are functionally arranged as follows: the genioglossus originates from the apophysis geni superior, and the geniohyoid muscle – from the inferior point (the intrinsic tongue muscle the first and the latter that inserts distally on the hyoid bone). There are also some insertions of the mylohyoid and pharyngeal constrictor muscles supplied additionally by the pterygomandibular ligament (located in the mandible's inner part).

There are insertions of several muscles on the body of the hyoid, originated either from the tongue or the mandible likely to the geniohyoid and mylohyoid muscles, as well as the sternohyoid, sternothyroid, thyrohyoid, and omohyoid ones. There is the insertion of the hyoglossus on the hyoid horns, the pharyngeal constrictor muscles, the stylohyoid, as well as the tendinous pulley of the digastric muscle. There is also the longitudinal superior muscle insertion took place, the longitudinal inferior muscle, and the stylohyoid ligament on the distal part of the horns. Two longitudinal muscles are the internal tongue muscles.

In this regard, seven pairs of these muscles hold the hyoid bone in place and cause it to move when needed. Two of them pull the hyoid bone upward and forward. One pulls it upward and backward. One pulls it upward, and three – downward. Therefore, it was suggested that the forward movement of the chin would cause changes in the hyoid bone position and, as a result, lead to an increase in the PAS volume.

The normal morphology, volume, choke point, and growth pattern of the upper airway were described by Schendel *et al.* (2011). The authors studied 1,300 normal subjects from 6 to 65 years of age and found out that the usual choke point was in the retroglossal space.

Other researchers showed a significant increase in both lateral and anteroposterior airway dimensions with maxillomandibular advancement (Abramson *et al.*, 2011; Fairburn *et al.*, 2007). They concluded that the changes were secondary to the enlargement of the entire velopharynx by elevating the tissues and increasing the tension on the suprahyoid and

velopharyngeal muscles. Based on Pouseille's law, as the radius increases and the height decreases, the resistance decreases. Therefore, an increase in the surface area due to an increase in the anteroposterior and transverse dimensions combined with a decrease in the total airway height results in a total decrease in airway resistance. Airway resistance was most likely also decreased because of the increased airway volume and the decreased airway height, but this required further investigation.

In the first case of segmental chin osteotomy, the most outstanding discovery is probably the increase in the anteroposterior airway dimension that is always less than the transverse airway dimension in cases with maxillomandibular advancement surgery (Schendel *et al.*, 2012; Brown *et al.*, 2013).

Knowledge about the preoperative smallest cross-sectional area (choke-point size) and its position allows surgery to be more precisely planned. For example, a small retroglossal cross-sectional area can be entirely corrected by chin advancement, if it is sufficiently large and the plane of osteotomy is performed high enough.

The CBCT study accounts for the airway shape and size only when the patient is awake, static, and in the upright, seated position. When the patient is in the supine position and asleep, the tissues relax further and can obstruct the airflow. Thus, it is understandable that any measurements of the airway will be worse during normal sleeping in the supine position when the muscles are relaxed.

Furthermore, the study was limited by two cases, presenting two different (controversial) results. This is why more work needs to be done in this area to allow precise planning based on the expected airway changes when chin surgery is used.

## 5. CONCLUSIONS:

Isolated segmental chin osteotomy provides predictable esthetic results in the correction of different mandible anterior deformities. The present study evaluated two patients without OSAS by a 3-dimensional analysis; therefore, clinical correlations in the increase between the PAS and OSAS parameters (apnea-hypopnea index, body mass index, oxygen saturation, etc.) are not possible.

Currently, the protocol of orthodontic examination includes CBCT data used to

diagnose skeletal and dental deformations, which are also ideal for detecting the anatomic obstruction of the upper airway space. CBCT images are an important and required instrument for revealing the area of the decreased airway space and for quantitative evaluation of its volume on different levels, as well as for diagnosing skeletal and dental deformations using a 3D-cephalometric analysis.

Bimaxillary surgery with forward movement and counterclockwise rotation in the sagittal plane is performed on patients with obstructive sleep apnea syndrome to increase the upper airway space. However, this surgery is technically complicated and requires a long rehabilitation time for the patient. Moreover, it significantly changes the appearance of the patient with big (more than 5 mm) forward movements.

In this regard, the use of less traumatic surgery, which can affect the retroglossal area and the tongue position to increase the upper airways, seems more promising in the context of achieving positive dynamics in addressing such medical issues. The study proved that segmental chin osteotomy could increase the pharyngeal airway space, which is associated with the forward movement of the mental area of the mandible and hyoid bone and the tongue muscles following. Such surgery can be an effective way of treatment with a high success rate for patients with an anatomic obstruction of the upper airway, who cannot withstand bimaxillary orthognathic surgery but still want improvements.

The study is limited by two cases with different effects. That is why further examination is needed to test the hypothesis that an increase in the hypopharyngeal region, associated with genioplasty, is clinically effective for OSAS.

### RESUMO

A eletrofloculação é uma técnica de tratamento de efluente líquido que tem sido largamente usada devido à sua simplicidade de operação e aplicação em diversos tipos de efluentes. O objetivo do trabalho foi avaliar a eficiência do tratamento por eletrofloculação com monitoramento e controle automático de um efluente de indústria têxtil, considerando ainda um estudo de viabilidade de uso de geração fotovoltaica. Os ensaios de eletrofloculação foram realizados com efluente bruto, em reator de batelada com eletrodos de alumínio, e com cuba de vidro. Utilizou-se um sistema eletrônico, constituído de sensores e um microcontrolador, para controlar a corrente e monitorar as variáveis de tensão, temperatura e tempo, processando os dados e enviando-os a um computador. O volume tratado a cada ensaio foi de 3 litros e submetidos às correntes de 1 e 2A, retirando alíquotas em 5, 10, 15 min. Os parâmetros analisados foram: pH, condutividade, turbidez, Demanda Química de Oxigênio e varredura de absorbância na faixa de 200 a 800 nm. As amostras apresentaram na região do visível uma banda com a máxima absorbância em 670nm, assim optou-se por avaliar o sistema nesse comprimento de onda. Os resultados dos ensaios de eletrofloculação mostraram que a melhor remoção de turbidez, DQO e absorbância em 670nm ocorreram nas condições de 2A/10min, com eficiência média acima de 70%. A partir do projeto elaborado de energia fotovoltaica para o sistema de tratamento, foi constatado que a melhor estratégia é conectar o sistema fotovoltaico à rede de energia elétrica. Por meio de simulação financeira foi possível identificar grande economia de energia que compensam os custos com a instalação do sistema fotovoltaico. Pode-se concluir, portanto, que o sistema tem eficiência no tratamento de efluente têxtil e que a demanda de energia elétrica consegue ser atendida por energia fotovoltaica, permitindo que o projeto seja sustentável.

### ABSTRACT

Electroflocculation is a technique for liquid effluent treatment that has been widely used due to simplicity in operation and to the possibility of application in different types of effluents. This study aimed to evaluate the electroflocculation treatment efficiency, monitoring and controlling an effluent automatically from the textile industry, also considering a feasibility study to photovoltaic generation application. The electroflocculation tests were performed with raw effluent, in a batch reactor containing aluminum electrodes and glass vat. Sensors and a microcontroller make up the electronic system, which monitors and controls voltage, temperature, and time variables and also processes and sends the data to the computer. The tests consist of applying 1 and 2A current in a 3 liters volume taking aliquots in 5, 10, 15 min. The parameters analyzed were: pH, conductivity, turbidity, Chemical Oxygen Demand, and absorbance sweep in 200 to 800 nm range. The samples presented in the visible region a band with the maximum absorbance at 670nm; thus, it was decided to evaluate the system at this wavelength. The results of the electroflocculation tests showed that the best removal of turbidity, COD, and absorbance at 670nm occurred in the conditions of 2A / 10min, with average efficiency above 70%. A photovoltaic system was projected to meeting the demand for the energy electroflocculation system, whose analysis found that the best strategy is connecting the photovoltaic system to the electric power grid. Through financial simulation, It was identified as a significant energy-saving which offsets costs related to system installation. In conclusion, the system developed is efficient in textile effluent treatment and that the photovoltaic

system meets the demand for energy from the electroflocculation system, ensuring project sustainability.

## 1. INTRODUÇÃO:

A poluição das águas superficiais e subterrâneas por efluentes líquidos provoca graves mudanças nas características físicas, químicas e biológicas as quais interferem na qualidade da água e praticamente impossibilitando o seu uso pelo ser humano (Crini e Lichtfouse, 2019).

A legislação ambiental, através das Resoluções CONAMA nº 357/2005 e nº 430/2011, dispõe que os efluentes de qualquer fonte poluidora somente poderão ser lançados diretamente nos corpos d'água após o devido tratamento e desde que obedeçam às condições padrões. Diante dessas exigências as empresas e indústrias buscam a implementação de sistemas de tratamento de efluentes. O sistema ideal para a empresa ou indústria é a integração do processo que gera o efluente com um processo que promova a recirculação ou reúso da água. Para que isso seja viável é necessário um processo de tratamento de efluente líquido de alta eficiência e baixo custo (Crini e Lichtfouse, 2019).

Diante dos inúmeros processos de tratamento de efluentes líquidos, a eletrofloculação (ou eletrocoagulação) é uma técnica que tem sido largamente estudada (Sen *et al.*, 2019; Babu *et al.*, 2019) devido à sua simplicidade de operação e aplicação em diversos tipos de efluentes tais como: têxtil (Núñez *et al.*, 2019; Tomassoni *et al.*, 2019), indústria de processamento de coco (Crespilho *et al.*, 2004; Jose *et al.*, 2019), laticínio (Dallago *et al.*, 2012; Tchamango *et al.*, 2020), lavanderia industrial (Orssatto *et al.*, 2016; Nugroho *et al.*, 2020), água pluvial (Zhang *et al.*, 2012; Carvalho *et al.*, 2019), reciclagem de papel (Katal e Pahlavanzadeh, 2011; Izadi *et al.*, 2018), doméstico (Kurt *et al.*, 2008; Bracher *et al.*, 2019), refinaria de óleos vegetais (Preethi *et al.*, 2020; Swati *et al.*, 2020), metais tóxicos (Koby et al., 2017; Krystynik *et al.*, 2019).

Esta técnica de tratamento faz uso de corrente elétrica para a geração de agentes coagulantes/floculantes em reações de oxidação. Os metais mais utilizados nos eletrodos de sacrifício são o ferro (Fe) e o alumínio (Al) devido a eficácia no processo de floculação e ao seu baixo custo (Sen *et al.*, 2019). Entretanto, a

eficiência do sistema pode alterar entre os eletrodos de ferro (Fe) e alumínio (Al) (Sher *et al.*, 2019; Aygun *et al.*, 2019; Papadopoulos *et al.*, 2019).

Para garantir a eficiência do sistema de eletrofloculação no processo de remoção dos contaminantes do efluente, é fundamental monitorar e controlar: a corrente elétrica aplicada, a distância entre os eletrodos, a agitação, o tempo de eletrólise, a condutividade do efluente, o pH inicial do efluente e a temperatura (Hashim *et al.*, 2019; Bracher *et al.*, 2019; Nidheesh *et al.*, 2020).

O consumo de energia elétrica, que se faz necessário na operação do sistema de tratamento por eletrofloculação, é uma das principais desvantagens ao defrontá-lo com sistemas convencionais, pois a mesma pode ser cara em certos lugares (Mollah *et al.*, 2001). Normalmente o consumo de energia contribui acima de 50% do gasto unitário (Mao *et al.*, 2008).

Dentre várias fontes de energia a energia solar fotovoltaica se destaca por ter a capacidade de se instalar em qualquer lugar, gerando eletricidade no mesmo local de utilização, por ter baixa necessidade de manutenção e por ser autossuficiente e renovável (Sampaio e González 2017). Estudos realizados por Pavón-Silva *et al.* (2018) e Khemila *et al.* (2018), em que ambos trabalharam com efluentes sintéticos (produzidos com corantes distintos), com eletrodos de alumínio, com reator de eletrofloculação de fluxo contínuo e com módulos fotovoltaicos conectados diretamente ao reator, obtiveram respectivamente uma eficiência de remoção dos corantes de 70% e 95%, demonstrando que é possível utilizar essa fonte de energia. Entretanto Pavón-Silva *et al.* (2018), salienta que além da eficiência de remoção de poluentes no efluente é importante também levar em consideração os custos de implementação dessa fonte de energia.

Diante do exposto e frente a escassez dos recursos naturais e contaminação dos recursos hídricos este trabalho visou montar e avaliar em escala laboratorial um sistema de tratamento para efluente líquido gerado por empresa têxtil, utilizando a técnica de eletrofloculação com monitoramento e controle

automático, considerando ainda um estudo de viabilidade econômica de uso de geração de energia fotovoltaica.

## 2. MATERIAIS E MÉTODOS:

Com base na tipologia do efluente proposto para os ensaios de tratamento por eletrofloculação optou-se pelo efluente bruto de uma empresa localizada no município de Linhares/ES, na qual apresenta atividade de lavanderia (descoloração) e tingimento. Esse processo industrial gera grande volume de efluente e com enorme diversidade e complexidade de compostos orgânicos e inorgânicos tóxicos em emulsão, os quais se destacam os corantes (Kumar e Saravanan, 2017; Hossini *et al.*, 2017; Samanta *et al.*, 2019).

As amostras foram coletadas na caixa de entrada da estação de tratamento de efluentes da empresa nos dias 26/04/18, 14/06/18, 12/04/19, 10/05/19 e 31/05/19. A caracterização do efluente foi realizada no laboratório de química do Ifes *campus* Linhares por meio dos seguintes parâmetros: pH, condutividade, turbidez, demanda química de oxigênio (DQO). As análises foram realizadas seguindo metodologias propostas pelo "Standart Methods for the Examination of Water and Wasterwater" (Rice *et al.*, 2012).

### 2.1. Reator de bancada

O reator de batelada foi construído com eletrodos de alumínio constituído por 8 lâminas com dimensões de 19 cm de comprimento, 3 cm de largura, e 1 mm de espessura (Figura 1). A cuba foi construída em vidro com as seguintes dimensões: 20 cm de altura, 20 cm de comprimento e 10 cm de largura.

O reator foi alimentado por uma fonte de corrente contínua regulável, ou seja, que viabilize o ajuste dos valores da intensidade da corrente a ser aplicada no efluente.

Durante o processo de eletrofloculação é necessário que a corrente elétrica permaneça constante. Ocorre que no início do processo a resistência do meio aquoso (eletrólito) é maior, assim se faz necessário aplicar uma tensão mais alta para um dado valor de corrente. Com o decorrer da reação de oxidação são liberados íons de alumínio ( $Al^{3+}$ ) aumentando a condutividade e consequentemente diminuindo a resistência elétrica apresentada pelo eletrólito, sendo assim, o valor de tensão para manter a corrente constante deve ser menor.

Desta forma, foi necessário monitorar a tensão e ainda a temperatura a fim de realizar as análises necessárias. O sistema eletrônico utilizado para fazer o monitoramento e controle dos ensaios de eletrofloculação foi composto por um microcontrolador Atmega328P presente na plataforma Arduino Nano, sendo o responsável pela atuação, leitura e envio de informações do reator para o computador através de uma interface USB.

Para ler e armazenar os valores da tensão aplicada aos eletrodos, foi necessário realizar um condicionamento de dados, por meio de um circuito divisor de tensão resistivo, e um filtro com uso de capacitor.

A leitura da temperatura foi realizada por meio do sensor DS18B20 que possui uma faixa de medição de  $-55^{\circ}C$  a  $125^{\circ}C$ , exatidão de  $0.5^{\circ}C$ . A comunicação entre sensor e microcontrolador foi realizada através das bibliotecas "Dallas Temperature e OneWire".

As informações coletadas e tratadas pelo microcontrolador foram enviadas a um computador portátil por meio de uma comunicação serial com a porta USB. O software PLX-DAQ foi utilizado em conjunto com um software de edição de planilhas para receber, armazenar e exibir todas as variáveis do processo em uma planilha (Figura 2).

A Figura 3 apresenta o sistema eletrônico montado.

### 2.2. Ensaios de eletrofloculação

Os ensaios foram realizados com as amostras coletadas nos dias 12/04/19, 10/05/19 e 31/05/19. O volume do efluente a cada ensaio foi de 3 litros e manteve sob constante agitação (300 rpm), com auxílio de agitador magnético. Essas amostras foram submetidas a correntes de 1 e 2A, recolhendo alíquotas de 100ml nos tempos de 5, 10 e 15 minutos. Para a remoção das alíquotas adotou-se o seguinte procedimento: desligar a agitação, esperar 2 minutos para o material flotar ou sedimentar, e com auxílio de uma pipeta posicionada no centro da cuba retirar o volume de 100ml.

As alíquotas foram filtradas à vácuo com papel de filtro qualitativo que retém partículas maiores que  $19\mu m$  (marca: J. Prolab). Esse procedimento foi adotado para evitar possíveis variações nos resultados relativos aos diferentes tempos de flotação ou sedimentação das partículas de cada amostra. Posteriormente foram executados os ensaios dos parâmetros:

pH, turbidez, demanda química de oxigênio (DQO) e varredura de absorvância na faixa de 200 a 800 nm em espectrofotômetro Agilent-Cary60/UV-Vis.

### 2.3. Energia fotovoltaica

Analisando a literatura e outros trabalhos que utilizam a energia fotovoltaica de forma a prover o fornecimento de energia a sistemas de eletrofloculação, foram levantadas três possíveis maneiras de trabalhar com o sistema fotovoltaico: I) sistema *off-grid* com armazenamento de energia em baterias (Vieira e Cavalcante, 2018; de Lima *et al.*, 2019); II) sistema *off-grid* conectado ao sistema de eletrofloculação sem meios de armazenamento (de Lima *et al.*, 2019; Rahmani *et al.*, 2017; Balabel *et al.*, 2014); III) sistema *grid-tie* (conectado à rede elétrica de forma híbrida ao fornecimento de energia da concessionária) (Akikur *et al.*, 2013) utilizando a compensação de crédito de energia conforme resolução (ANEEL, 2012).

A primeira opção foi desconsiderada por estar em desacordo com a proposta de sustentabilidade ambiental do trabalho. A utilização de baterias aumenta o custo do sistema e seu descarte gera resíduos poluentes. As outras duas formas descritas foram analisadas para avaliar a melhor proposta. Foi realizado um projeto para atendimento da unidade consumidora considerando apenas o consumo de energia demandado pelo sistema de eletrofloculação, com o intuito de comparar financeiramente o custo de implementação do sistema e o tempo de retorno do investimento.

## 3. RESULTADOS E DISCUSSÃO:

### 3.1. Características físico-químicas do efluente bruto.

Na Tabela 1 encontram-se os resultados de caracterização das amostras de efluente bruto coletadas em dias e anos distintos. Verifica-se que os valores de pH do efluente bruto apresentaram próximo de neutro, com exceção da amostra 5 que apresentou caráter ácido (pH = 4,1). Para esse tipo de efluente já foram encontrados na literatura valores de pH da faixa ácida (Pizato *et al.*, 2016), próximo da neutra (Afanga *et al.*, 2020; Bener *et al.*, 2019; Núñez *et al.*, 2019; Nidheesh *et al.*, 2020) até a alcalina (Cerqueira *et al.*, 2009; Soltani *et al.*, 2019).

O efluente bruto apresentou valores de DQO (173 a 410 mgO<sub>2</sub>/L) próximos aos

resultados encontrados por Afanga *et al.* (2020), Bener *et al.* (2019), Soltani *et al.* (2019) e Núñez *et al.* (2019), e baixo comparando com os teores encontrados por Cerqueira *et al.* (2009), 1.179 a 2.553 mgO<sub>2</sub>/L, por Nidheesh *et al.* (2020) 1.727 mgO<sub>2</sub>/L, e por Pizato *et al.* (2016), 659 mgO<sub>2</sub>/L.

As amostras do efluente de estudo apresentaram valores de turbidez (62,8 a 249 NTU) superior aos identificados por outros trabalhos: Cerqueira *et al.* (2009), 8,0 a 75,3 NTU; Pizato *et al.* (2016), 37 NTU; Bener *et al.* (2019), 15 a 35 NTU; Núñez *et al.* (2019), 12,5 NTU.

A condutividade do efluente de estudo apresentou resultado elevado (52 a 121 mS/cm) comparando com efluentes de mesma tipologia caracterizados por Cerqueira *et al.* (2009), Pizato *et al.* (2016), Afanga *et al.* (2020), Bener *et al.* (2019) e Núñez *et al.* (2019) que foram respectivamente 4,61; 0,80; 2,5; 8,96 e 0,67 mS/cm. Para sistema de tratamento por eletrofloculação esse resultado se torna vantajoso, pois diminui a resistividade do meio demandando menor tensão para manter a corrente.

### 3.2. Avaliação da eficiência do sistema de tratamento

Os resultados dos ensaios de eletrofloculação para a amostra 3 (Tabelas 2 e 3), mostram que a melhor remoção de turbidez e DQO ocorreram nas condições de 2A/10min. com eficiência de 87% e 80% respectivamente. Verifica-se também para a amostra 4, nas mesmas condições (2A/10min.), um comportamento semelhante com remoção de turbidez de 93%, e DQO de 81%. Essa mesma eficiência foi encontrada por Cerqueira *et al.* (2009), turbidez 98% e DQO 87%, entretanto as condições de ensaio foram diferentes, tais como: ajuste de pH inicial do efluente bruto para o valor próximo de 7; formato dos eletrodos de alumínio; corrente 15A; tempo de eletrofloculação de 30min.

Todavia a amostra 5 apresentou comportamento diferente, pois ocorreu melhor remoção de turbidez em 1A/5min de 91%, e a DQO apresentou uma redução máxima de 57% em 2A/10min, valor esse bem inferior comparado com as outras amostras. Sabe-se que o pH inicial do efluente a ser tratado por eletrofloculação influencia significativamente na eficiência do processo (Cerqueira *et al.*, 2009; Tchamango *et al.*, 2020; Nidheesh *et al.*, 2020; Bener *et al.*, 2019). O valor do pH inicial (4,1)

dessa amostra foi o que possivelmente corroborou para a queda da remoção de DQO, esse comportamento também foi constatado por Vepsäläinen e Sillanpää (2020) e por Nidheesh *et al.* (2020), usando eletrodos de alumínio.

Verifica-se que o pH do efluente no decorrer dos ensaios (Tabela 2) aumenta gradualmente até valores na faixa de neutro. Esse sistema de tratamento tem a grande vantagem de manter ou tornar o efluente com pH neutro por meio das reações que ocorrem no catodo, redução do hidrogênio, e no anodo, oxidação do alumínio seguida de hidrólise.

As varreduras espectrais das 3 amostras de efluente bruto filtrado (Figura 4) apresentaram na região do visível uma banda com a máxima absorvância em 670nm. Esse pico de absorvância próximo a esse comprimento de onda também foi constatado por Pizato *et al.* (2016) e Afanga *et al.* (2020) num efluente de mesma tipologia. Assim optou-se por calcular o percentual de remoção ou verificar a eficiência dos ensaios por meio da absorvância nesse comprimento de onda.

A remoção da absorvância em 670nm foi muito rápida, pois logo nos primeiros 5min de ensaio constata-se uma remoção de 74 a 97% na menor amperagem (Tabelas 2 e 3). Assim pode-se considerar que o sistema tem uma ótima eficiência na remoção de substâncias que absorvem nesse comprimento de onda.

A varredura espectral de todos os ensaios realizados com a amostra 3 (Figura 5) mostra que também há decaimento da absorvância em toda a faixa do visível e em parte do ultravioleta. O mesmo comportamento foi observado com as amostras 4 e 5.

Foi possível verificar visualmente a remoção de sólidos em suspensão e a cor das amostras do efluente (Figuras 6 e 7) durante os ensaios. Constata-se também que em ambos os ensaios das amostras 3 e 4 em 2A/15min o sistema encontra-se saturado do agente floculante, pois há uma espessa camada de espuma branca, o que provocou possivelmente o aumento da turbidez e da DQO (Tabela 2).

Durante os ensaios de eletrofloculação a temperatura do efluente foi monitorada e manteve-se entre 25 a 27°C, assim averigua-se que nos ensaios esse parâmetro não variou de forma significativa.

### 3.3. Viabilidade de uso de energia fotovoltaica

Com os resultados da porcentagem média de remoção das amostras 3, 4 e 5 dos parâmetros DQO, turbidez e absorvância em 670nm contidos na Figura 8, verifica-se que a melhor condição do ensaio de eletrofloculação foi com 2A no tempo de 10min.

Nesta condição, foi possível identificar que o maior consumo de energia aconteceu quando o valor de tensão era de 5,38V com 0,6Wh/l (Tabela 2).

De acordo com Kobya *et al.* (2006) o consumo de energia em um reator batelada pode ser calculado utilizando-se a equação 1 adaptada:

$$E = \frac{V \cdot i \cdot t}{1000 \cdot v} \quad (\text{Eq. 1})$$

Onde:

E: energia em KWh

V: tensão elétrica aplicada ao processo em Volts (V).

i: corrente elétrica aplicada em amperes (A).

T: tempo de aplicação da corrente ou tempo de processo (h).

v: volume tratado em m<sup>3</sup>.

Conhecendo o valor de consumo médio mensal encontrado pela equação, para um sistema *grid-tie* (conectado à rede elétrica), o projeto foi realizado considerando inclinação dos módulos em 19° Norte e dados de irradiação solar diária média mensal do local com a base de dados do SunData (Brito, 2008). Uma análise de viabilidade econômica foi levantada considerando os principais critérios abordados na literatura (Lopez, 2012; Türkay e Telli, 2011) Bazilian *et al.*, 2013; de Almeida *et al.*, 2017) como custo de instalação, previsão de geração, tempo de retorno do investimento e economia total no final da vida útil do sistema implantado.

Foi prevista a instalação de 13 módulos Canadian Solar CS6U-320P. Os módulos estariam conectados em série a um inversor Fronius Primo 5.0-1 possibilitando a conexão na rede. A Tabela 4 apresenta a irradiação solar média mensal da região considerada e a Figura 9 apresenta a previsão de geração com o consumo médio considerado do sistema. Com estimativa de preço baseado no mercado, considerando

equipamentos e instalação, o custo médio de instalação do sistema é aproximadamente R\$25.940.

A fim de avaliar financeiramente a viabilidade da utilização deste sistema, considerando a unidade consumidora do grupo A, com geração de energia e abatimento em crédito no horário fora ponta, a simulação foi realizada observando as relevâncias de algumas variáveis como incidência de impostos, previsão de aumento do Kwh ao ano e valor de tarifa baseado na regulamentação da distribuidora onde se encontra a indústria (EDP, 2019). A Figura 10 apresenta o resultado da simulação. Considerando a vida útil do sistema em 25 anos, a economia total simulada ao final da vida útil do sistema é de R\$88.716,00.

Para um sistema *off-grid* (sem bateria), seria necessário a construção de um conversor eletrônico que permitisse a regulação do ponto de operação elétrico do sistema. Considerando o número de módulos utilizados no projeto anterior (sistema *grid-tie*) e a previsão de geração mostrada na Figura 9, é possível identificar que durante os meses de abril a agosto o sistema fotovoltaico geraria menos energia do que seria consumido pelo sistema de eletrofloculação. Contudo se o sistema for *grid-tie* (conectado à rede elétrica), isso não seria um problema, pois a energia excedente nos meses de alta geração compensaria os meses de baixa geração (a energia seria convertida em créditos).

Assim, em um sistema *off grid* (sem bateria), é necessário projetar levando em consideração o pior mês de geração (junho), desse modo o número de módulos deverá aumentar para 17. A previsão de geração é retratada na Figura 11.

Em uma pesquisa de mercado é possível identificar que mesmo sem a utilização do inversor, o preço do sistema sem conexão à rede passa a não compensar pelo fato da geração ser superdimensionada para atender aos meses de menor radiação solar na região. Neste caso o projeto mais indicado é o sistema *grid-tie* (conectado à rede elétrica) que atende à demanda de energia do sistema de eletrofloculação de maneira eficiente.

#### 4. CONCLUSÕES:

A técnica de eletrofloculação com eletrodos de alumínio mostrou-se ter grande eficiência na remoção de substâncias que absorvem a luz na faixa espectral do visível

independente das características iniciais do efluente bruto têxtil. As remoções de turbidez e Demanda Química de Oxigênio (DQO) também foram eficientes, entretanto tiveram variações significativas principalmente em função do pH inicial do efluente.

As condições dos ensaios de eletrofloculação que levaram a melhor eficiência de tratamento do efluente de estudo foram quando se manteve a corrente em 2A e tempo de processo 10 min.

Em relação ao consumo de energia, as simulações financeiras, baseadas no projeto de um sistema fotovoltaico, apontam que o sistema do tipo *grid-tie* (conectado à rede elétrica) é a melhor forma de atender à demanda de energia do sistema de eletrofloculação. Apesar dos custos de instalação do sistema fotovoltaico, a longo prazo, existe não apenas um retorno do investimento, mas também economia financeira, além de garantir a sustentabilidade da proposta.

#### RESUMO

A Indonésia tem mais de 25.000-30.000 espécies de plantas. A floresta tropical da Indonésia é uma fonte enorme de compostos metabólicos secundários benéficos para a saúde e a vida. Um dos tesouros é Bajakah Kalalawit (*Uncaria gambir roxb*), uma planta endêmica de Bornéu que se acredita hereditariamente curar tumores e cânceres. Esta pesquisa pertence a um estudo educacional que reconstruiu o conhecimento científico sobre as bioatividades de Bajakah por compostos de metabólitos secundários como etnomedicina e teve como objetivo restabelecer a pesquisa científica sobre bioatividades de Bajakah para medicamentos contra câncer e tumores. A madeira e a raiz de Bajakah Kalalawit da Floresta Nacional de Conservação, Samarinda, Indonésia, foram tomadas como amostra. O pó da raiz e da madeira foi isolado e extraído para seus compostos de metabólitos secundários usando água, etanol + água e etanol + hexano como solventes. Os isolados resultantes foram testados quanto à fitoquímica, estrutura e bioatividade em relação a *Bacillus subtilis* e *Escherichia coli* (*E. Colli*). Os resultados foram apoiados por testes de estrutura com a espectroscopia FTIR que mostrou a aparência de captação de grupos funcionais para hidroxila, carbonila e aromática que correspondiam às moléculas secundárias de metabólitos. A análise dos dados obtidos concluiu que a raiz de Bajakah e o extrato de madeira contêm a atividade inibitória de células e tumores cancerígenos, pois contêm compostos de metabólitos secundários, incluindo terpenos, fenóis, alcalóides e flavonóides. Os compostos de metabólitos secundários dos isolados de Bajakah foram capazes de inibir a atividade de *Bacillus subtilis* e *Escherichia coli* (*E. Colli*).

#### ABSTRACT

Indonesia has more than 25.000-30.000 plant species. The Indonesia tropical forest is a huge source for secondary metabolite compounds that are beneficial for health and life. One of the treasures is Bajakah (*Uncaria gambir roxb*), a plant endemic to Borneo that has been hereditarily believed to cure tumors and cancers. This research belongs to an educational study that reconstructed scientific knowledge about secondary metabolite compounds' bioactivities of Bajakah as ethnomedicine and aimed at reestablishing scientific research on bioactivities of Bajakah for cancer and tumor medication. The wood and root of Bajakah Kalalawit of the National Conservation Forest, Samarinda, Indonesia, were taken as the sample. The root and wood powder was isolated and extracted for their secondary metabolite compounds using water, ethanol + water, and ethanol + hexane as the solvents. The resulted isolates were tested for the phytochemical, structure, and bioactivity towards *Bacillus subtilis* and *Escherichia coli* (*E. Colli*). The results were supported by structure tests with FTIR spectroscopy, which showed the appearance of uptake of functional groups for hydroxyl, carbonyl, and aromatics that corresponded to secondary metabolite molecules. The analysis of the obtained data concluded that the Bajakah root and the wood extract contain the inhibitory activity of cancer cells and tumors because they contain compounds of secondary metabolites, including terpenes, phenols, alkaloids, and flavonoids. The secondary metabolite compounds from the Bajakah isolates were able to inhibit the activity of *Bacillus subtilis* and *Escherichia coli* (*E. Colli*).

## 1. INTRODUCTION:

Indonesia has more than 25.000-30.000 plant species, 17.000 islands/isles, 50 types of ecosystem, and 300-700 ethnics (Kartawinata, 2010). The ethnic diversity of Indonesia has resulted in sundry cultures, traditions, and local wisdom. One of the local wisdom is the use of surrounding diversity as a medication of various diseases (Amir *et al.*, 2017). Locals made use of local plants to maintain their health and are known as medicinal plants. The knowledge of medicinal plants is generally passed on orally so that knowledge is only limited to a group of people and is known as indigenous science (Kandowangko *et al.*, 2018; Aziz *et al.*, 2018). This knowledge is vulnerable to degradation due to cultural acculturation and modernization (Mikako & Hirokazu, 2020). Thus, it needs to be conserved (Daval, 2009).

A study revealed that more than 80% of secondary metabolite compounds found in local plants are used as the first compound source to common medicines in the pharmaceutical industry (Fabricant & Farnsworth, 2001). Currently, research on local herbs as the traditional medication is a hot topic, particularly in ethnobotanical, ethnomedicine, and ethnopharmacology field (Kandowangko *et al.*, 2018; Evrizal *et al.*, 2013; Silalahi & Nisyawati, 2018; Lense, 2012).

Research about secondary metabolite compounds and their bioactivation to a particular disease is essential to carry out. Indonesia's tropical forest is a huge source for secondary metabolite compounds that are beneficial for health and life (Silalahi *et al.*, 2015). One of the treasures is Bajakah (*Uncaria gambir roxb*), a plant endemic to Borneo that has been hereditarily believed to cure tumors, cancers; maintain stamina, and stop bleeding (Moris, 2020).

The utilization of Bajakah (*Uncaria gambir roxb*) by the Inland Dayak Tribe should be discussed in the context of ethnomedicine. Etymologically, the word 'ethnomedicine' means the connectivity of ethnicity and medicine as Local Knowledge. Scientifically, ethnomedicine is said to be a perception and conception of local people, and Local Knowledge in understanding health, or, research about the medical system of traditional ethnic (Bhasin, 2007). An ethnomedicine study is done to understand health from society's point of view to be reconstructed into scientific knowledge (Walujo, 2011; Walujo, Ethnopharmacology:

Knowledge Saintification for the Development of the Drug and Pharmaceutical Chemical Industry in Indonesia, 2013).

Ethnomedicine, reviewed from the scientific field, is a part of anthropology that discusses medicinal plants, their ethnobotanics, and marketing (Lee *et al.*, 2008). Moreover, it also talks about the bioactivities of the secondary metabolite compounds, morphological characters, and scientific explanations (Andrade-Cetto & Heinrich, 2011; Toksoy *et al.*, 2010). Some medicines that derive from local knowledge include the quinine which is adapted from the knowledge of Incas who had long used *Chinchona* as a cure for malaria. There is also reserpine from *Rauwolfia serpentina* that has been utilized by the Indian community to reduce blood pressure. These medicines are some of the proofs of ethnomedicine development in recent years. Mostly, ethnomedicine focuses on finding new secondary metabolite compounds that are beneficial for modern medicine production to heal fatal diseases like tumors and cancers.

Public knowledge is correct at a certain level, but people should also be educated about a scientific explanation of a medicinal plant and how to protect the plant, which belongs to Indonesia's natural wealth (Hisa *et al.*, 2018). The conservation knowledge of medicinal plants has been owned by the Marori tribe in Masur Merauke National Park and Karimunjawa society (Sudarmin *et al.*, 2017; Supriyadi & Sudarmin, 2020). This research intends to follow the prior study, which provides explanations to the society about the medicinal plants. Frankly, this study is the development of the preceding research as it uses ethnoscience, ethnomedicine, and strengthened by laboratory-based scientific work in explaining people's indigenous science. Similar research was also done in Vietnam by (Hoang *et al.*, 2008), Turkey (Akbulut & Bayramoglu, 2013), Pakistan (Aziz *et al.*, 2018), China (Lee *et al.*, 2008), Cameroon (Mikako & Hirokazu, 2020), while here in Indonesia (Hisa *et al.*, 2018; Hariyadi & Ticktin, 2010; Kandowangko *et al.*, 2018; Lense, 2012; Silalahi, 2014; Silalahi *et al.*, 2015; Silalahi & Nisyawati, 2018; Supriyadi & Sudarmin, 2020; Septriyanto *et al.*, 2018) are researchers who are interested in benefitting local herbs as treatments.

Stood on the above description, inquiry-based findings related to the medicinal plant's advantage must be informed. The process of scientific explanation of public knowledge through scientific work-based inquiry in the laboratory is

known as the process of reconstructing scientific knowledge (Sudarmin *et al.*, 2019; Sumarni *et al.*, 2016; Sumarni & Sudarmin, 2019). This research is important because public knowledge about traditional medicine and local knowledge has not been widely explained scientifically (Sumarni, 2019). Previously, students of a High School in Palangkaraya experimented on mice induced by tumor and cancer cell growth substances. They used Bajakah (*Uncaria gambir roxb*) extract as a medication for the mice and were succeeded in saving the mice's life. This result turns out to be the basis of this research in examining the ability of Bajakah (*Uncaria gambir roxb*) like cancer and tumor medication, and the secondary metabolite compounds contained in it.

This research belongs to an educational study that reconstructed scientific knowledge about secondary metabolite compounds' bioactivities of Bajakah as ethnomedicine and aimed at reconstructing scientific research on bioactivities of Bajakah for cancer and tumor medication.

## 2. MATERIALS AND METHODS:

### 2.1. Ethnomedicine Data Retrieval

The interviewee of this study was a 37 years-old native man who resides near the National Conservation Forest, Samarinda in which Bajakah comes from. He is also one of the many residents there who has used Bajakah to cure cancer and tumors for his relatives or neighbors. At present, he is cultivating and selling Bajakah wood and root to various regions through online sales. The research team obtained ethnomedical information about Bajakah and pictures from him.

This research belongs to an ethnomedicine study in which the data were gathered from a face to face interview (Akbulut & Bayramoglu, 2013). Referring to (Reyes-García *et al.*, 2006) and Praptiwi's procedure (Praptiwi, 2004), the focus of this research include: (1) the local name of Bajakah (*Uncaria gambir roxb*); (2) characteristics of plants; (3) how plants are used as medicines; (4) ways to mix the fruit extract; (5) additive ingredients for the fruit extract; (6) its medical components; (7) ways of community conservation; and (8) seedling pattern. The data of organoleptic secondary metabolite test, phytochemical test, structure test, and antibacterial test were carried out a scientific inquiry at the Chemistry and Microbiology Laboratory at UNNES (Universitas Negeri Semarang). The inquiry activities included isolation and identification of phytochemicals and

secondary metabolite structures of Bajakah (*Uncaria gambir roxb*) wood and root. The procedure of isolation and identification refers to the Organic Chemistry practicum manual prepared by UNNES Bioorganic Lecturer Team (Supartono *et al.*, 2016), which is explained as follows.

### 2.2. The Isolation of Bajakah (*Uncaria gambir roxb*) Wood and Root from Borneo Island

The first step was the making of bajakah wood and root powder. The dried wood and root were cut into pieces and put in a blender at the UNNES Chemistry Laboratory to make a fine powder. The fine powder obtained was weighed (25 grams) then extracted by maceration procedure in an Erlenmeyer Glass (Merck brand) Volume 200 mL using 100 mL water solvent or 100 mL ethanol solvent. The solvent replacement was done every 24 hours and then filtered with filter paper. All macerates were collected and put into a rotary evaporator at 100°C. Furthermore, the remaining filtrate was evaporated using a vaporizer cup in a water bath until a thick, stable isolate extract was obtained. As for other wood and root powder, the isolation

Other than the isolation and extraction, a Soxhlet process was performed to the powder sample using 50 mL of ethanol + 50 mL of n-hexane (pa) and 50 mL of ethanol + 50 mL of benzene (pa) for approximately 48 hours. At this point, the ethanol and benzene mixture solvent has isolated all secondary metabolite components of the powder. Then the solvent obtained from the Soxhlet process was filtered with filter paper. All the extractant was put into a rotary evaporator at 100°C, and the obtained extractant as Bajakah (*Uncaria gambir roxb*) isolate was ready for Phytochemical testing, structure test with FTIR; and bioactivity testing of *Bacillus subtilis* and *Escherichia coli* bacteria.

In addition to the use of ethanol and benzene, a mixture of ethanol and hexane (pa) was also employed. The process of Soxhlet process was the same for both samples from the root and wood powder, which was carried out, referring to Supartono *et al.* (2016).

### 2.3. Procedure for Phytochemical Test of the Secondary Metabolite Compounds

This step of the research was the phytochemical test and bioactivity test of Bajakah extract against *Bacillus subtilis* (positive gram bacteria) and *Escherichia coli* (negative gram bacteria). The research results were then

compared to prior studies and expert judgment about Bajakah (*Uncaria gambir roxb*), to produce an established reconstruction of scientific knowledge.

The procedure of the phytochemical test included several stages. Firstly, alkaloids identification using Mayer and Dragendorf reagents. The extract, as a result of isolation using methanol solvent, is shaken. If a deposition/white mist or an orange-red precipitate is formed after the Dragendof reagent is added, it means that the Bajakah extract (*Uncaria gambir roxb*) contains Alkaloids. Secondly, steroids and terpenoids identification using Liberman Buchard. If a red or purplish-red mist is formed, then Bajakah isolate contains terpenoids, and if a green or bluish-green mist is formed, Bajakah isolate restrains steroids. Third, the flavonoids test by putting a few drops of Bajakah isolate water fraction into a test tube, then adding Mg metal powder and a few drops of concentrated HCl. If it turns into pink to red (except for isoflavones), then the isolate carries Flavonoids. Fourth, phenolics identification by adding several drops of water fraction of Bajakah isolate (*Uncaria gambir roxb*) into a test tube, then putting in some drops of  $\text{FeCl}_3$ . If it turns into blue or purplish-blue, the isolate is declared phenolics-positive. Last, saponin identification by putting 1 mL of Bajakah isolate water fraction into a test tube then shaken for 1-2 minutes. If temporal foam (which lasts for about 5 minutes) is built, then the isolate is saponin-positive.

#### 2.4. Secondary Metabolite Structure Test with Elmer 100 FT-IR Perki Spectroscopy

In assisting the results of scientific knowledge reconstruction, a molecular structure test of Bajakah's secondary metabolite structures was carried out using the Perkin Elmer 100 FT-IR (Fourier Transform Infra-Red) spectroscopy. FT-IR is a tool employed to analyze chemical compounds. The infrared spectra of a compound can provide a picture and molecular structure of the compound. In this research, the test was carried out by following (Srinovaz, 2014) procedure.

In strengthening the findings of the phytochemical test and explaining scientifically about the secondary metabolites' type of functional group, the structural analysis of the functional group type was done using the Perkin Elmer Inc 10 FTIR spectroscopy (Figure 2a). A total of 1 mL of the sample (Figure 2b) of secondary metabolites as the result of Bajakah wood and root soxhletation with ethanol-hexane was prepared. Before analyzing the type of

functional group, a temperature reconditioning and FTIR tool examination was carried out. Temperature recondition was done by pressing the power button and set to 25°C. After the tool was set up, the next step is to examine the spectra data scan by clicking the background icon, filling in the sample name by writing 'Bajakah root sample-1', and set the wavenumber between 750-3700  $\text{cm}^{-1}$ . A total of 1  $\mu\text{L}$  of the root sample was injected into the holder sample; then, the scan icon was clicked. After about 8 minutes, a spectrum scan appeared.

The obtained data were then compared to those saved in the reference section by clicking 'setup' on the toolbar, chose 'compare references' → 'compare.' In a few minutes, the comparison spectra scan appeared. To sort the most similar references, the researchers clicked 'libraries' and 'search.' After a while, some references for the spectra scan popped out for the researcher to analyze carefully. Once the desired references have been found, then the researchers closed and saved them.

#### 2.5. Antibacterial Bioactivity Test

The test procedure modified what has been done by (Septiani *et al.*, 2017; Alen *et al.*, 2009). The preparation stage included bacterial rejuvenation, bacterial suspension making, paper disc making (6 mm in diameter), preparation of negative and positive control, and concentration series making of 300, 400, and 500 mg/mL. The antibacterial activity test used was the Disc Diffusion method (Kirby-Bauer Test). The suspension of bacteria test, as much as 20  $\mu\text{L}$ , was placed in the Petri then rubbed with sterile cotton on the test media (Gardjito *et al.*, 2007). This procedure was repeated twice. The paper disc was placed above the media, which included 50  $\mu\text{g}$  of Ciprofloxacin as the positive control, 20% of DMSO as the negative control, and 300, 400, and 500 mg/mL of ethanol extract from Bajakah (*Uncaria gambir roxb*) isolate. The media were then incubated at 37°C for 24 hours, then the inhibition zone diameter was measured with a caliper expressed in millimeters.

#### 2.6. Data Analysis

The research data obtained through interviews with a source person in the research site were analyzed. The questions raised to the interviewee were the local name, the characteristics of the plant, the benefits of the extract, and how to use it as cancer and tumor medication. the resource person, Moris (37 years

old) is a native of the community residing near the national tropical forest, Samarinda, Indonesia. The data taken from the interview were then reconstructed based on Hempel (2014). To strengthen the reconstruction, a series of experiments were conducted in the Chemistry Laboratory of Universitas Negeri Semarang (UNNES) for the isolation process, phytochemical tests, structure tests, and bioactivity tests of the extracts against *Bacillus subtilis* and *Escherichia coli*. The conclusion was drawn up based on the experiment results.

### 3. RESULTS AND DISCUSSION:

#### 3.1. The Results of Scientific Knowledge Reconstruction

Figure 1 presents the pictures of Bajakah wood and Bajakah tea taken by Moris in the research location. Moreover, the data and information obtained from the interview are shown in Table 1. Departing from the interviewee's answers regarding the local name and characteristics, the researchers did a literature study to seek for the suitability of the data with the scientific records and found that the Bajakah mentioned by the interviewee belongs to Bajakah kalalawit (*Uncaria gambir roxb*). Its leaves vary from yellow, brown, and white, while its small flower is purple, pink, and white.

The species contains phenol, antibacterial agent, and high catechins to prevent heart disease, obesity, and help the formation of collagen (Medical Team Universitas Lambung Mangkurat, 2017). The polyphenols are found in the leaves, yet the type and content are mainly affected by the leaf's age. Gardjito *et al.* (2007) revealed that Bajakah (*Uncaria gambir roxb*) leaves were found in compounds belonging to the phenolic group. The bioactivity of the compounds is presented in Table 2.

The results of interviews, as presented in Table 1, reveals that the community consumes Bajakah by brewing/boiling the dried leaves, bark, or root and drinks it as tea. This process, in the context of scientific knowledge, is called as the maceration process. The tea was observed to have reddish to yellow in color, which indicates the existence of secondary metabolite compounds. Moreover, in the context of scientific knowledge related to chemistry solution, the secondary metabolite compounds are solute while water is the solvent (Supartono *et al.*, 2016). Another way to consume Bajakah is revealed by Ujung (2017) who found that there are two other species of

Bajakah found in Borneo that are also believed to cure cancer, they are Bajakah Tampala (*Spatholobus Littoralis Hassk*) and Bajakah Lamei which grows in the tropical forest. Its stem stores much edible water and this water is commonly consumed as medication to cure various diseases.

The phytochemical test results of Bajakah (*Uncaria gambir roxb*) wood and root extract carried out in this research are presented in Table 3. Table 3 indicates that the secondary metabolite compounds found in this research are similar to those found in the prior study done in Universitas Lambung Mangkurat. These compounds result in bioactivity towards cancer and tumor cells that serve as an antibacterial agent and could stop bleeding. Nevertheless, the Ministry of Health of the Republic of Indonesia (2018) stated that Bajakah (*Uncaria gambir roxb*) as cancer, tumor, or other medication needs further research. On the other hand, Bajakah tea has empirically proven to hinder cancer cells by releasing hydroxyl compounds to bond the cancer cell so that the cell growth obstructs. For that reason, this study strengthens the phytochemical test for Bajakah isolates extracted using an organic solvent.

The results of the structure test with the FTIR Spectra Tool (Figure 3) showed the absorption of the main functional groups of secondary metabolite compounds contained in Bajakah wood and root extracts, namely hydrosol, carbonyl, aromatic, and methyl. The FT-IR spectra strengthen the presence of -OH (hydroxyl) and a carbonyl group. The presence of C-O bonds reinforces the -OH group, while the presence of methyl and methylene is shown by 100-1120 cm<sup>-1</sup>. The results test indicated compatibility with the phytochemical test results of secondary metabolite compounds of bark and root extract (Medical Team of Universitas Lambung Mangkurat, 2017).

This research only shows the concordance of the research findings with the results by the medical team of Lambung Mangkurat University (2017) and has not shown the molecular structure of the secondary metabolite compounds. This follows the aim of the research, which is to explain why Bajakah extract is a potential cancer drug. This question has been answered by the finding of phenolics, terpenoids, and saponins. The analysis results showed that these metabolites can inhibit cancer cells since active groups such as hydroxyl groups (-OH) weaken cancer cells with different patterns of mechanisms (Panda, A, and Gunawan, YE, 2018, Maulidie, M *et al.*, 2019 ). This is in line with Maulina *et al.* (2019), indicating that the phytochemical test for the rough extract of Bajakah

root dissolved in ethanol results in the same type of secondary metabolite compounds found in this research.

Furthermore, to determine the chemical structure and specific types for each secondary metabolite, it is necessary to purify and separate Bajakah extract isolates, followed by further structural analysis tests which include Ultra Violet Visible (UV-Vis) spectroscopy, Nuclear Magnetic Resonance (NMR) spectroscopy, and Carbon Core Magnetic Resonance Spectroscopy (13C-NMR). This research has not done these tests yet.

### 3.2 The Bioactivity of Secondary Metabolite Compounds with *Bacillus subtilis* and *Escherichia coli*

The antibacterial test toward Bajakah (*Uncaria gambir roxb*) isolates employed *Bacillus subtilis* (positive gram) and *Escherichia Coli* (negative gram). The test results are displayed in Figure 4 and Table 4. Based on this experiment, the inhibition test was performed, and the results are presented in Table 4. Table 4 informs that the bioactivity test results found that Bajakah (*Uncaria gambir roxb*) root isolate dissolved in water has a stronger inhibition zone than the isolate dissolved in ethanol or n-hexane, both for *Bacillus subtilis* and *Escherichia coli*. In other words, this study has granted a scientific explanation that Bajakah wood and root contain saponins as the antibacterial agent (Medical Team of Universitas Lambung Mangkurat, 2017). This is different from what was found by Gardjito *et al.* (2007) that the extract of polyphenols and catechins from *Uncaria gambir roxb* does not show as an antibacterial agent for *Escherichia coli*, but has antibacterial properties against *Staphylococcus aureus*.

## 4. CONCLUSIONS:

1. Bajakah root and wood extract contain the inhibitory activity of cancer cells and tumors as they contain secondary metabolite compounds including terpenes, phenols, alkaloids, and flavonoids;
2. The results were supported by structure tests with Perken Elmer Inc.10 FTIR spectroscopy, which showed the appearance of functional groups for hydroxyl (-OH), Carbonil (-C = O), which were bound to the structure of secondary metabolites. When cancer occurs, the oxidation process happens in Deoxyribonucleic acid (DNA), and the secondary metabolites found in Bajakah have the ability to act as antioxidants to

protect DNA and inactivate the growth of cancer cells.

3. The secondary metabolite compounds from Bajakah isolates were able to inhibit the activity of *Bacillus subtilis* and *Escherichia coli* (*E.Coli*), yet the isolates embattle *E.Coli* stronger than *B. Subtili*.

This reconstruction is in line with what has been stated in the previous results about Bajakah's bioactivities. In other words, this research confirms prior research claims about the benefits of Bajakah (*Uncaria gambir roxb*) as ethnomedicine. It is expected that this study could be a reference for stakeholders to make use of Bajakah (*Uncaria gambir roxb*) as an alternative for cancer and tumor medication.

## 5. ACKNOWLEDGMENTS:

Thank you to the Ministry of Research and Technology of Indonesia for the funding through the Higher Education Primary Research scheme year 2020-2022.

**Table 1. The Interview Results**

| No  | Question   | Answer   |
|-----|--|--|
| 1.  | What does Dayak Tribe call it?   | Bajakah, it means roots in Dayak language. Literature results found that the Latin name for Bajakah is <i>Uncaria gambir roxb.</i>   |
| 2.. | What are the characteristics of Bajakah?   | Vines are growing from the trunk of the tree and twisting to other trees. The tree diameter can reach 10 cm. The color of the trunk is brown, the surface of the bark is rough and dry. It secretes clear water when cut. The surface of the leaves is delicate, and the branches grow parallel right and left.  |
| 3.  | Before going viral, what are the advantages of the plant believed by the locals? | Bajakah has been used as a medicine for generations by the Dayak tribe since the nomadic life. Mostly, they consumed it to increase stamina when clearing forest land into fields.   |
| 4.  | Which part of the tree is mostly utilized?                                       | The main part is wood, but the leaves and roots are also used.   |
| 5.  | What are the steps of extracting Bajakah traditionally?                          | Separate wood with its bark, wash and rinse with running water. Cut into small pieces having 4-5 cm in length and dry it under the sunlight. Then boiled the dried wood in 1 liter of water up to reaching the remaining half (0.5 liters). The water could be consumed 3 times a day.<br><br>The wood could also be processed into powder by finely grounding the dried wood. The Bajakah powder can be consumed by brewing a teaspoon of powder with a glass of hot water. |
| 6.  | Do the locals conserve the plant?  | They only take big Bajakah tree having > 4 cm in diameter.   |
| 7.  | What do you know about Bajakah's chemical contents and their benefits?           | I am aware of the research results done by scientists in Universitas Lambung Mangkurat that there are 40 substances advantageous for health, mainly for killing cancer/tumor cells.  |

**Table 2. The Bioactivity of Secondary Metabolite Compounds Found in Bajakah or *Uncaria gambir roxb* (The Medical School of Lambung Mangkurat, 2017)**

| No | Secondary Metabolite Compound | Bioactivity and Benefit for Health   |
|----|-------------------------------|--|
| 1. | Saponins                      | Antibacterial, lower cholesterol levels, fight cancer cells, prevent tumors, increase body immune  |
| 2. | Alkaloids                     | Relieve pain and stop bleeding   |
| 3. | Steroids                      | Accelerate wound healing, and maintain stamina   |
| 4. | Terpenoids                    | Antiseptic, anti-microbial, overcome the menstrual disorder, relieve inflammation, malaria and diabetes medication                       |
| 5. | Flavonoids                    | Antioxidant, treat allergies, infections, and arthritis, restore damaged cells due to free-radical, maximalize the benefits of vitamin C |
| 6. | Tanin                         | Antioxidant, diarrhea medication, the antibacterial, antidote  |
| 7. | Phenolics                     | Antioxidant, prevent heart disorders, prevent cancer cell growth, prevent diabetes   |

### RESUMO

A modelagem de muitos fenômenos em vários campos, como matemática, física, química, engenharia, biologia e astronomia, é feita pelas equações diferenciais parciais não lineares (PDE). A equação do telégrafo hiperbólico é uma delas, onde descreve as vibrações de estruturas (por exemplo, edifícios, vigas e máquinas) e é a base para equações fundamentais da física atômica. Existem vários métodos analíticos e numéricos para resolver a equação do telégrafo. Uma solução analítica considera enquadrar o problema de uma forma bem compreendida e calcular a resolução exata. Também ajuda a entender as respostas para o problema em termos de precisão e convergência. Esses métodos analíticos têm limitações com precisão e convergência. Portanto, um novo método analítico aproximado é proposto para lidar com restrições neste artigo. Este método usa as séries de Taylors em sua derivação. O método proposto foi usado para resolver a equação hiperbólica de segunda ordem (equação Telegraph) com a condição inicial. Três exemplos foram apresentados para verificar a eficácia, precisão e convergência do método. As soluções do método proposto também foram comparadas com as obtidas pelo método de decomposição adomiana (ADM) e pelo método de análise de homotopia (HAM). A técnica é fácil de implementar e produz resultados precisos. Em particular, esses resultados mostram que o método proposto é eficiente e melhor que os outros métodos em termos de precisão e convergência

### ABSTRACT

The modeling of many phenomena in various fields such as mathematics, physics, chemistry, engineering, biology, and astronomy is done by the nonlinear partial differential equations (PDE). The hyperbolic telegraph equation is one of them, where it describes the vibrations of structures (e.g., buildings, beams, and machines) and are the basis for fundamental equations of atomic physics. There are several analytical and numerical methods are used to solve the telegraph equation. An analytical solution considers framing the problem in a well-understood form and calculating the exact resolution. It also helps to understand the answers to the problem in terms of accuracy and convergence. These analytic methods have limitations with accuracy and convergence. Therefore, a novel analytic approximate method is proposed to deal with constraints in this paper. This method uses the Taylors' series in its derivation. The proposed method has used for solving the second-order, hyperbolic equation (Telegraph equation) with the initial condition. Three examples have presented to check the effectiveness, accuracy, and convergence of the method. The solutions of the proposed method also compared with those obtained by the Adomian decomposition method (ADM), and the Homotopy analysis method (HAM). The technique is easy to implement and produces accurate results. In particular, these results display that the proposed method is efficient and better than the other methods in terms of accuracy and convergence.

**Keywords:** *Hyperbolic Telegraph Equation, Taylors' Series, Analytical Solution, Accuracy, Non-Linear Operator.*

## 1. INTRODUCTION:

Telegraph's equation is one of the most investigated problems in over four centuries. Generally, it uses to model the vibrations of structures (e.g., buildings, beams, and machines) and are the basis for fundamental equations of atomic physics (Kolesov and Rozov 2000) and (Alonso, Mawhin, and Ortega 1999).

Linear hyperbolic telegraph equation with constant coefficients forms a blend between wave propagation and diffusion by inserting a term that accounts for impacts of finite velocity to the standard heat or mass transport equation (El-Azab and El-Gamel 2007). In general, the hyperbolic telegraph equation is used in signal analysis for transmission and propagation of electrical signals (A. C. Metaxas 1983) and also has applications in other fields (see (Roussy and Pearce 1998) and the references therein).

Recently, several numerical methods have been developed to solve hyperbolic partial differential equations (PDEs), such as alternating direction implicit Method (Mohanty, Jain, and Arora 2002), Chebyshev tau method (Saadatmandi and Dehghan 2010), Interpolating Scaling Functions Method (Lakestani and Saray 2010), Radial Basis Functions method (De Su, Jiang, and Jiang 2013), collocation points and approximating the solution using thin-plate splines radial basis function method (Dehghan and Shokri 2008), the modified cubic B-Spline differential quadrature method (Singh 2016), a collocation method (Bhatia 2014), reproducing kernel method (Mustafa Inc 2013), finite difference method (Mohanty, Jain, and George 1996), and (Gao and Chi 2007), finite volume method (Sheng and Zhang 2018), Galerkin method (Liu and Gu 2004), improved element-free Galerkin method (Zhang, Deng, and Liew 2014), and differential quadrature method (Mittal and Jiwari 2009).

These techniques consider a necessitate as computational resources to solve some problems that appear in other sciences such as in image processing. Still, these techniques perhaps complicated and require a high computational cost, which means they consume time and effort to obtain accurate solutions for different nonlinear PDEs. Furthermore, applying these techniques may be needed for transforming. Thus, they do not avoid linearization, discretization, or any realistic assumption to providing an efficient solution. Therefore, it is considered positive points for analytical methods to find the most efficient and high accurate approximate and exact solutions for the linear and nonlinear differential equations.

There are many used methods to find the exact solution, such as ( $G'/G$ ) expansion method (Naher, Hasibun 2012), sine-cosine method (Yusufoğlu and Bekir 2006), homogeneous balance method (Eslami, Fathi Vajargah, and Mirzazadeh 2014), etc. Also, there are other types of analytical techniques that combine between exact and approximate methods called semi-analytical methods. For instance, Adomian decomposition method (ADM), (Adomian 1994) and (Biazar and Ebrahimi 2007), the extended of ADM (Al-Badrani et al. 2016), Differential transform method (DTM) (Zhou 1986), Variational Iteration Method (VIM) (Biazar, Ebrahimi, and Ayati 2008), Reduced differential transform method (Mukesh K. Awasthi, R. K. Chaurasia 2013) and (Srivastava, Awasthi, and Chaurasia 2014), Daftardar-Gejji-Jafaris (DGJ) method (Sari, Gunay, and Gurarslan 2014), Reimann method (ZAVALANI 2009), Sumudu method (Ayad Ghazi Naser Al-Shammari, Wurood R. Abd AL-Hussein 2018), the modified simple equation method (Taghizadeh et al. 2012), Chebyshev Cardinal functions are used for solution of the second-order one-dimensional telegraph Equation (Dehghan and Lakestani 2009), Wavefront solutions of a nonlinear telegraph equation (Gilding and Kersner 2013), Homotopy analysis method (HAM) (Raftari and Yildirim 2012), Homotopy analysis Sumudu transform method (Rathore et al. 2012) and (Jaradat et al. 2018), and Laplace transform method (LDM) (Jaradat et al. 2018).

One of these methods which has received much concern is the Adomian decomposition method (ADM) (Biazar and Ebrahimi 2007). The ADM has been employed to solve various linear and nonlinear models. The ADM yields a rapidly convergent series solution with much less computational work (Abbaoui and Cherruault 1995). The ADM is unlike the traditional numerical methods, where ADM is used extensively to solve nonlinear differential equations because it works based on calculation Adomian polynomials for non-linear terms (El-Sayed and Kaya 2004) and (Inc 2007).

While, the analytical solutions of differential transform method (DTM) (Zhou 1986), are as a polynomial form which is different from the traditional higher-order Taylor series method because the Taylor series method needs huge computational for large orders. So, the DTM uses a different procedure to obtain an analytic Taylor series solution of the PDE (Abazari and Borhanifar 2010) and (Saeideh Hesam 2011).

On the other hand, many complicated problems in different applied sciences have been

successfully solved by the homotopy analysis method (HAM) (Liao 1992), (Kheiri, H. 2011), (Usman et al. 2013) and (Arafa, Rida, and Mohamed 2011). Homotopy perturbation method (HPM) (Raftari and Yildirim 2012), as well has been handled successfully to solve many linear and non-linear PDEs (Roul 2010).

Whereas, the variational iteration method (VIM) (He 1997), can be applied to solve all types of linear or nonlinear differential equations, constant or variable coefficients with homogeneous or inhomogeneous (Yulita Molliq et al. 2009) because it effectively used to solve these nonlinear equations with a good convergent to the exact solutions.

All of these analytical methods are active and strong in finding solutions of linear and non-linear PDEs. Generally, the basic idea of these methods through writing the PDEs in the form of operators after that the inverse operator of time (or space) is taken to calculate the solutions on the interval of the solution domain. In the last years, these analytical methods have been enhanced and modified and to overcome the difficulties encountered in the numerical methods such as finding the exact solution, round off errors, low accuracy, and weak convergence by many researchers. Furthermore, these analytical methods introduced efficiency and high accuracy in finding the analytical exact and approximate solutions for the linear and nonlinear PDEs, which made a good impression of these analytical methods. Therefore, we proposed a new analytical approximate method for solving linear and non-linear telegraph equations.

This study aimed to find approximate analytical solutions to the linear and nonlinear telegraph equation with initial conditions and boundary conditions by using a novel analytical technique, which is considered as extending and developing to that in (wiwatwanich, 2016). This technique is based on the Taylor series, which is efficient to solve nonlinear equations. Also, the survey reveals that no attempt has ever been made to study the current model by using this technique. These reasons stimulated and employed us to solve the linear and intricate nonlinear problems such as the one-dimensional telegraph equation. Several test problems are given, and their results are compared with the solutions obtained by ADM (Biazar and Ebrahimi 2007), and HAM (Raftari and Yildirim 2012) to confirm the excellent accuracy and small absolute errors of the proposed technique.

## 2. MATERIALS AND METHODS:

In this work, it was studied the second-order one-dimensional telegraph equation:

$$\frac{\partial^2 w}{\partial t^2} + 2\alpha \frac{\partial w}{\partial t} + \beta^2 w = \frac{\partial^2 w}{\partial x^2} + h(x, t) + g(w), \quad (1)$$

where  $w = w(x, t)$ ,  $\alpha$ ,  $\beta$  are real constants,  $x$  is distance and  $t$  is time, with initial and boundary conditions

$$w(x, 0) = h_0(x), \quad \frac{\partial w}{\partial t}(x, 0) = h_1(x), \quad (2)$$

$$w(0, t) = g_0(t), \quad w(1, t) = g_1(t), \quad t \geq 0 \quad (3)$$

If  $g(w) = 0$ , then equation (1) called a linear hyperbolic telegraph equation in a double conductor, the equation (2.1) is satisfied in both the electric voltage and current. For  $\alpha > 0$ ,  $\beta = 0$  it represents a damped wave equation, and  $\alpha > \beta > 0$ , which is called a telegraph equation.

### 2.1. Generating an analytical approach

In this section, the basic ideas for constructing a novel analytical approach will be discussed. Let us consider the initial value problems:

$$w_{tt}(x, t) = G(w_t, w, w_x, w_{xx}, \dots), \quad (4)$$

with initial condition

$$w(x, 0) = h_0(x), \quad w_t(x, 0) = h_1(x). \quad (5)$$

By using the integral for the two sides of equation (4) from 0 to  $t$ , we get

$$w_t(x, t) - w_t(x, 0) = \int_0^t F[w] dt,$$

$$w_t(x, t) - h_1(x) = \int_0^t F[w] dt.$$

Then,

$$w_t(x, t) = h_1(x) + \int_0^t F[w] dt, \quad (6)$$

where  $G[w] = G(w_t, w, w_x, w_{xx}, \dots)$ .

Then, when the integral of two sides of equation (6) is used from 0 to  $t$ , we obtain

$$w(x, t) - w(x, 0) = h_1(x)t + \iint_0^t G[w] dt dt,$$

$$w(x, t) - h_0(x) = h_1(x)t + \iint_0^t G[w] dt dt.$$

Thus,

$$w(x, t) = h_0(x) + h_1(x)t + \iint_0^t G[w] dt dt. \quad (7)$$

The Taylor series is extended for  $G[w]$  about  $t = 0$ , which is

$$G[w] = G[w_0] + G'[w_0]t + G''[w_0]\frac{t^2}{2!} + G'''[w_0]\frac{t^3}{3!} + \dots + G^{(n)}[w_0]\frac{t^n}{n!} + \dots \quad (8)$$

Substituting equation (8) by equation (7), we get

$$\begin{aligned} w(x, t) &= h_0(x) + h_1(x)t + G[w_0]\frac{t^2}{2!} + G'[w_0]\frac{t^3}{3!} + \\ &G''[w_0]\frac{t^4}{4!} + \dots + G^{(n-2)}[w_0]\frac{t^n}{n!} + \dots, \\ &= a_0 + a_1t + a_2\frac{t^2}{2!} + a_3\frac{t^3}{3!} + \dots + a_n\frac{t^n}{n!} + \dots, \end{aligned} \quad (9)$$

where

$$a_0 = h_0(x),$$

$$a_1 = h_1(x),$$

$$a_2 = G[w_0],$$

$$a_3 = G'[w_0],$$

$$a_n = G^{(n-2)}[w_0].$$

where  $n$  is the highest derivative of  $u$ . The formal of Equation (9) is expand Taylor's series for  $w$  about  $t = 0$ . This means

$$a_0 = w(x, 0),$$

$$a_1 = \frac{\partial}{\partial t} w(x, 0),$$

$$a_2 = \frac{\partial^2}{\partial t^2} w(x, 0),$$

$$a_3 = \frac{\partial^3}{\partial t^3} w(x, 0),$$

$$a_n = \frac{\partial^n}{\partial t^n} w(x, 0).$$

### 2.1.1 Test Problems

**Example 1.** Solve the following linear telegraph equation (Lakestani and Saray 2010):

$$\begin{aligned} \frac{\partial^2 w(x, t)}{\partial t^2} + 2\alpha \frac{\partial w(x, t)}{\partial t} + \beta^2 w(x, t) &= \frac{\partial^2 w(x, t)}{\partial x^2} + \\ (3 - 4\alpha + \beta^2)e^{-2t} \sinh(x), \\ \frac{\partial^2 w(x, t)}{\partial t^2} &= -2 \\ &\alpha \frac{\partial w(x, t)}{\partial t} - \beta^2 w(x, t) + \frac{\partial^2 w(x, t)}{\partial x^2} \\ &+ (3 - 4\alpha + \beta^2)e^{-2t} \sinh(x). \end{aligned} \quad (10)$$

**Solution:**

By the following equation (4), we can note after rewrite equation (10):

$$\begin{aligned} F[w] &= -2\alpha \frac{\partial w(x, t)}{\partial t} - \beta^2 w(x, t) + \frac{\partial^2 w(x, t)}{\partial x^2} + \\ (3 - 4\alpha + \beta^2)e^{-2t} \sinh(x), \\ a_0 &= h_0(x) = \sinh(x), \end{aligned}$$

$$a_1 = h_1(x) = -2 \sinh(x),$$

$$\begin{aligned} a_2 &= G[w_0] = -2\alpha \frac{\partial w(x, 0)}{\partial t} - \beta^2 w(x, 0) + \\ &\frac{\partial^2 w(x, 0)}{\partial x^2} + (3 - 4\alpha + \beta^2)e^{-2(0)} \sinh(x) \\ &= -2\alpha a_1 - \beta^2 a_0 + (a_0)_{xx} + \\ &(3 - 4\alpha + \beta^2)e^{-2(0)} \sinh(x) \\ &= 4\alpha \sinh(x) - \beta^2 \sinh(x) + \\ &\sinh(x) + (3 - 4\alpha + \beta^2) \sinh(x) \\ &= (4\alpha - \beta^2) \sinh(x) + \sinh(x) + \\ &3 \sinh(x) + (-4\alpha + \beta^2) \sinh(x) \\ &= 4 \sinh(x) \end{aligned}$$

$$\begin{aligned} G'[w] &= -2\alpha \frac{\partial^2 w(x, t)}{\partial t^2} - \beta^2 \frac{\partial w(x, t)}{\partial t} + \frac{\partial^3 w(x, t)}{\partial t \partial x^2} - \\ &2(3 - 4\alpha + \beta^2)e^{-2t} \sinh(x) \\ a_3 &= G'[w_0] = -2\alpha \frac{\partial^2 w(x, 0)}{\partial t^2} - \beta^2 \frac{\partial w(x, 0)}{\partial t} + \\ &\frac{\partial^3 w(x, 0)}{\partial t \partial x^2} - 2(3 - 4\alpha + \beta^2)e^{-2(0)} \sinh(x) \\ &= -2\alpha a_2 - \beta^2 a_1 + (a_1)_{xx} - \\ &2(3 - 4\alpha + \beta^2) \sinh(x) \\ &= -8\alpha \sinh(x) + 2\beta^2 \sinh(x) - \\ &2 \sinh(x) - 2(3 - 4\alpha + \beta^2) \sinh(x) \end{aligned}$$

$$\begin{aligned}
&= (-8 \alpha + 2\beta^2) \sinh(x) - \\
&2 \sinh(x) - 6 \sinh(x) + (8 \alpha - 2\beta^2) \sinh(x) \\
&= -8 \sinh(x).
\end{aligned}$$

Now by using equation (9),

$$\begin{aligned}
w(x, t) &= a_0 + a_1 t + a_2 \frac{t^2}{2!} + a_3 \frac{t^3}{3!} + \dots + a_n \frac{t^n}{n!} + \dots \\
&= \sinh(x) - 2 \sinh(x) t + 4 \sinh(x) \frac{t^2}{2!} - \\
&8 \sinh(x) \frac{t^3}{3!} + \dots \\
&= \sinh(x) (1 - (2t) + \frac{(2t)^2}{2!} - \frac{(2t)^3}{3!} + \dots) \\
&= \sinh(x) e^{-2t}.
\end{aligned}$$

Therefore, the graph of exact, analytical solutions, and absolute errors of example 1 for  $t = 1$  are given in Figure 1. Table 1 shows the absolute error using the proposed technique, ADM, and HAM of example 1 with  $t = 1, k = 0.001$  and different values of  $\alpha = 10$ , and  $\beta = 5$ .

When the value of  $n$  increases, the approximate solution gradually approaches the exact solution and the absolute error will decrease. Also, the values of  $\alpha$  and  $\beta$  do not affect the solution.

**Example 2.** Solve the following linear telegraph equation (Lakestani and Saray 2010):

$$\begin{aligned}
\frac{\partial^2 w(x, t)}{\partial t^2} + 2 \alpha \frac{\partial w(x, t)}{\partial t} + \beta^2 w(x, t) &= \frac{\partial^2 w(x, t)}{\partial x^2} - 2 \alpha \sin(t) \sin(x) + \beta^2 \cos(t) \sin(x), \\
\frac{\partial^2 w(x, t)}{\partial t^2} &= -2 \alpha \frac{\partial w(x, t)}{\partial t} - \beta^2 w(x, t) + \frac{\partial^2 w(x, t)}{\partial x^2} - 2 \alpha \sin(t) \sin(x) + \beta^2 \cos(t) \sin(x) \quad (11)
\end{aligned}$$

**Solution:** By the following equation (4), we can note after rewrite equation (11):

$$\begin{aligned}
G[w] &= -2 \alpha \frac{\partial w(x, t)}{\partial t} - \beta^2 w(x, t) + \frac{\partial^2 w(x, t)}{\partial x^2} - 2 \alpha \sin(t) \sin(x) + \beta^2 \cos(t) \sin(x), \\
a_0 &= h_0(x) = \sin(x),
\end{aligned}$$

$$a_1 = h_1(x) = 0,$$

$$\begin{aligned}
a_2 &= G[w_0] = -2 \alpha \frac{\partial w(x, 0)}{\partial t} - \beta^2 w(x, 0) + \\
&\frac{\partial^2 w(x, 0)}{\partial x^2} - 2 \alpha \sin(0) \sin(x) + \beta^2 \cos(0) \sin(x)
\end{aligned}$$

$$= -2 \alpha a_1 - \beta^2 a_0 + (a_0)_{xx} +$$

$$\begin{aligned}
&\beta^2 \sin(x) \\
&= -2 \alpha (0) - \beta^2 \sin(x) + (\sin(x))_{xx} + \\
&\beta^2 \sin(x)
\end{aligned}$$

$$= -\sin(x),$$

$$G'[w] = -2 \alpha \frac{\partial^2 w(x, t)}{\partial t^2} - \beta^2 \frac{\partial w(x, t)}{\partial t} + \frac{\partial^3 w(x, t)}{\partial t \partial x^2} - 2 \alpha \cos(t) \sin(x) - \beta^2 \sin(t) \sin(x),$$

$$\begin{aligned}
a_3 &= G'[w_0] = -2 \alpha \frac{\partial^2 w(x, 0)}{\partial t^2} - \beta^2 \frac{\partial w(x, 0)}{\partial t} + \\
&\frac{\partial^3 w(x, 0)}{\partial t \partial x^2} - 2 \alpha \cos(0) \sin(x) - \\
&\beta^2 \sin(0) \sin(x) \\
&= -2 \alpha a_2 - \beta^2 a_1 + (a_1)_{xx} - 2 \alpha \sin(x)
\end{aligned}$$

$$\begin{aligned}
&= 2 \alpha \sin(x) - \beta^2 (0) + (0)_{xx} - 2 \alpha \sin(x) \\
&= 0,
\end{aligned}$$

$$G''[w] = -2 \alpha \frac{\partial^3 w(x, t)}{\partial t^3} - \beta^2 \frac{\partial^2 w(x, t)}{\partial t^2} + \frac{\partial^4 w(x, t)}{\partial t^2 \partial x^2} + 2 \alpha \sin(t) \sin(x) - \beta^2 \cos(t) \sin(x),$$

$$\begin{aligned}
a_4 &= G''[w_0] = -2 \alpha \frac{\partial^3 w(x, 0)}{\partial t^3} - \beta^2 \frac{\partial^2 w(x, 0)}{\partial t^2} + \\
&\frac{\partial^4 w(x, 0)}{\partial t^2 \partial x^2} + 2 \alpha \sin(0) \sin(x) - \beta^2 \cos(0) \sin(x) \\
&= -2 \alpha a_3 - \beta^2 a_2 + (a_2)_{xx} - \\
&\beta^2 \sin(x) \\
&= -2 \alpha (0) + \beta^2 \sin(x) + \sin(x) - \\
&\beta^2 \sin(x) \\
&= \sin(x),
\end{aligned}$$

Now, by using the equation (9),

$$\begin{aligned}
w(x, t) &= a_0 + a_1 t + a_2 \frac{t^2}{2!} + a_3 \frac{t^3}{3!} + \dots + a_n \frac{t^n}{n!} + \dots \\
&= \sin(x) + (0)t + (-\sin(x)) \frac{t^2}{2!} + (0) \frac{t^3}{3!} + \\
&(\sin(x)) \frac{t^4}{4!} + \dots \\
&= \sin(x) - \sin(x) \frac{t^2}{2!} + \sin(x) \frac{t^4}{4!} + \dots \\
&= \sin(x) (1 - \frac{t^2}{2!} + \frac{t^4}{4!} + \dots) \\
&= \sin(x) \cos(t).
\end{aligned}$$

Therefore, the graph of exact, analytical solutions, and absolute errors of example 2 for  $t = 1$  are given in Figure 2. Table 2 shows the absolute error using the proposed technique, ADM, and HAM of example 2 with  $t = 1, k = 0.001$  and different values of  $\alpha = 10$ , and  $\beta = 5$ .

When the value of  $n$  increases, the approximate solution gradually approaches the exact solution and the absolute error will decrease. Also, the values of  $\alpha$  and  $\beta$  do not affect the solutions.

**Example 3.** Solve the following nonlinear telegraph equation (Bhatia 2014):

$$\begin{aligned}\frac{\partial^2 w(x,t)}{\partial t^2} + \frac{\partial w(x,t)}{\partial t} &= \frac{\partial^2 w(x,t)}{\partial x^2} - 2 \sin(w(x,t)) - \\ &\pi^2 e^{-t} \cos(\pi x) + 2 \sin(e^{-t}(1 - \cos(\pi x))), \\ \frac{\partial^2 w(x,t)}{\partial t^2} &= -\frac{\partial w(x,t)}{\partial t} + \frac{\partial^2 w(x,t)}{\partial x^2} - 2 \sin(w(x,t)) - \\ &\pi^2 e^{-t} \cos(\pi x) + 2 \sin(e^{-t}(1 - \cos(\pi x))).\end{aligned}\quad (12)$$

**Solution:** By the following equation (4), we can note after rewrite equation (12):

$$\begin{aligned}G[w] &= -\frac{\partial w(x,t)}{\partial t} + \frac{\partial^2 w(x,t)}{\partial x^2} - 2 \sin(w(x,t)) - \\ &\pi^2 e^{-t} \cos(\pi x) + 2 \sin(e^{-t}(1 - \cos(\pi x))), \\ a_0 &= h_0(x) = 1 - \cos(\pi x),\end{aligned}$$

$$a_1 = h_1(x) = -1 + \cos(\pi x),$$

$$\begin{aligned}a_2 &= G[w_0] = -\frac{\partial w(x,0)}{\partial t} + \frac{\partial^2 w(x,0)}{\partial x^2} - \\ &2 \sin(w(x,0)) - \pi^2 e^{-(0)} \cos(\pi x) + \\ &2 \sin(e^{-(0)}(1 - \cos(\pi x))) \\ &= -a_1 + (a_0)_{xx} - 2 \sin(a_0) - \\ &\pi^2 \cos(\pi x) + 2 \sin((1 - \cos(\pi x))) \\ &= 1 - \cos(\pi x) + \pi^2 \cos(\pi x) - \\ &2 \sin(1 - \cos(\pi x)) - \pi^2 \cos(\pi x) + \\ &2 \sin((1 - \cos(\pi x))) \\ &= 1 - \cos(\pi x),\end{aligned}$$

$$\begin{aligned}G'[w] &= -\frac{\partial^2 w(x,t)}{\partial t^2} + \frac{\partial^3 w(x,t)}{\partial t \partial x^2} - \\ &2 \cos(w(x,t)) \frac{\partial w(x,t)}{\partial t} + \pi^2 e^{-t} \cos(\pi x) + \\ &2 \cos(e^{-t}(1 - \cos(\pi x))) e^{-t}(-1 + \cos(\pi x)),\end{aligned}$$

$$\begin{aligned}a_3 &= G'[w_0] = -\frac{\partial^2 w(x,0)}{\partial t^2} + \frac{\partial^3 w(x,0)}{\partial t \partial x^2} - \\ &2 \cos(w(x,0)) \frac{\partial w(x,0)}{\partial t} + \pi^2 e^{-(0)} \cos(\pi x) + \\ &2 \cos(e^{-(0)}(1 - \cos(\pi x))) e^{-(0)}(-1 + \cos(\pi x)) \\ &= -a_2 + (a_1)_{xx} - 2 \cos(a_0)a_1 + \\ &\pi^2 \cos(\pi x) \\ &\quad + 2 \cos((1 - \cos(\pi x)))(-1 +\end{aligned}$$

$$\begin{aligned}\cos(\pi x)) \\ &= -1 + \cos(\pi x) - \pi^2 \cos(\pi x) - \\ &2 \cos(1 - \cos(\pi x))(-1 + \cos(\pi x)) \\ &\quad + \pi^2 \cos(\pi x) + 2 \cos((1 - \cos(\pi x)))(-1 + \cos(\pi x)) \\ &= -1 + \cos(\pi x),\end{aligned}$$

Now, by using the equation (9),

$$\begin{aligned}w(x,t) &= a_0 + a_1 t + a_2 \frac{t^2}{2!} + a_3 \frac{t^3}{3!} + \dots + a_n \frac{t^n}{n!} + \dots \\ &= (1 - \cos(\pi x)) - (1 - \cos(\pi x))t + \\ &(1 - \cos(\pi x)) \frac{t^2}{2!} - (1 - \cos(\pi x)) \frac{t^3}{3!} + \dots \\ &= (1 - \cos(\pi x))(1 - t + \frac{t^2}{2!} - \frac{t^3}{3!} + \dots) \\ &= (1 - \cos(\pi x))e^{-t}.\end{aligned}$$

Then, the graph of exact, analytical solutions, and absolute errors of example 3 for  $t = 1$  are given in Figure 3. Table 3 shows the absolute error using the proposed technique, ADM, and HAM of example 3 with  $t = 1, k = 0.001$ . When the value of  $n$  increases, the approximate solution gradually approaches the exact solution and the absolute error will decrease.

### 3. RESULTS AND DISCUSSION:

Three test problems are introduced for confirming the validity of the novel proposed technique, which used to find the solutions of linear and nonlinear one-dimensional telegraph equations. Figures (1-3) showed that the exact solution, analytical solution, and absolute errors at  $t = 1, k = 0.001$ . Also, the analytical solutions obtained by a proposed technique have been compared with the solutions obtained by ADM (Biazar and Ebrahimi 2007), and HAM (Raftari and Yildirim 2012) in three test examples, which are given in Tables (1-3). We then found that the analytical solutions obtained by a proposed technique are more identical to the exact solutions than those obtained using ADM and HAM of linear and nonlinear one-dimensional telegraph equation. Therefore, it can be seen that the absolute errors of the proposed technique are smaller than ADM and HAM, which are shown in Tables (1-3). More precisely, the measurement of absolute errors for these examples guarantees the ability of the proposed technique and its accuracy in finding the analytical solutions of linear and

nonlinear one-dimensional telegraph equation. Moreover, according to the computations that are introduced in the figures and tables, we can say that, the analytical technique is an effective and good technique to find the solutions of linear and nonlinear one-dimensional telegraph equations compared to the ADM, and HAM.

### 3.1. Convergence analysis

Consider the PDE (1.1) in the following form:

$$w(x, t) = G(w(x, t)), \quad (1)$$

where  $G$  is a nonlinear operator. The solution that obtained by the presented technique is equivalent to the following sequence:

$$S_n = \sum_{i=0}^n w_i = \sum_{i=0}^n \delta_i \frac{(\Delta t)^i}{(i)!}. \quad (2)$$

**Theorem 3.1** (Convergence of linear and nonlinear telegraph equation)

Let  $G$  be an operator from a Hilbert space  $H$  into  $H$  and  $w$  be the exact solution of equation (3.1). The approximate solution  $\sum_{i=0}^{\infty} w_i = \sum_{i=0}^{\infty} \delta_i \frac{(\Delta t)^i}{(i)!}$  is converged to exact solution  $w$ , when  $\exists 0 \leq \delta < 1$ ,  $\|w_{i+1}\| \leq \delta \|w_i\| \forall i \in \mathbb{N} \cup \{0\}$ .

**Proof:** We want to prove that  $\{S_n\}_{n=0}^{\infty}$  is a converged Cauchy sequence,

$$\|S_{n+1} - S_n\| = \|w_{n+1}\| \leq \delta \|w_n\| \leq \delta^2 \|w_{n-1}\| \leq \dots \leq \delta^n \|w_1\| \leq \delta^{n+1} \|w_0\|. \quad (3)$$

Now for  $n, m \in \mathbb{N}, n \geq m$  we get

$$\begin{aligned} \|S_n - S_m\| &= \|(S_n - S_{n-1}) + (S_{n-1} - S_{n-2}) + \dots + (S_{m+1} - S_m)\| \\ &\leq \|S_n - S_{n-1}\| + \|S_{n-1} - S_{n-2}\| + \dots + \|S_{m+1} - S_m\| \\ &\leq \delta^n \|w_0\| + \delta^{n-1} \|w_0\| + \dots + \delta^{m+1} \|w_0\| \\ &\leq (\delta^{m+1} + \delta^{m+2} + \dots + \delta^n) \|w_0\| = \\ &\delta^{m+1} \frac{1 - \delta^{n-m}}{1 - \delta} \|w_0\|. \quad (4) \end{aligned}$$

Hence,  $\lim_{n, m \rightarrow \infty} \|S_n - S_m\| = 0$ , i. e.,  $\{S_n\}_{n=0}^{\infty}$  is a Cauchy sequence in the Hilbert space  $H$ .

Thus, there exist  $S \in H$  such that  $\lim_{n \rightarrow \infty} S_n = S$ , where  $S = w$ .

**Definition 3.2** For every  $n \in \mathbb{N} \cup \{0\}$ , we define

$$\delta_n = \begin{cases} \frac{\|w_{n+1}\|}{\|w_n\|}, & \|w_n\| \neq 0 \\ 0, & \text{otherwise.} \end{cases} \quad (5)$$

**Corollary 3.3** From Theorem 3.1,

$$\sum_{i=0}^{\infty} w_i = \sum_{i=0}^{\infty} \delta_i \frac{(\Delta t)^i}{(i)!},$$

is converged to exact solution  $w$  when  $0 \leq \delta_i < 1$ ,  $i = 0, 1, 2, \dots$

To illustrate the convergence of analytical approximate solutions for the three examples, it was applied Corollary 3.3 as follows.

In the first example where  $(x, t) \in (0, 1)^2$ ,

$$\delta_1 = \frac{\|w_2\|}{\|w_1\|} = 0.7745966694 < 1,$$

$$\delta_2 = \frac{\|w_3\|}{\|w_2\|} = 0.5634361702 < 1,$$

$$\delta_3 = \frac{\|w_4\|}{\|w_3\|} = 0.4409585516 < 1.$$

In the second example where  $(x, t) \in (0, 1)^2$ ,

$$\delta_1 = \frac{\|w_2\|}{\|w_1\|} = 0.06211299938 < 1,$$

$$\delta_2 = \frac{\|w_3\|}{\|w_2\|} = 0.02773500981 < 1,$$

$$\delta_3 = \frac{\|w_4\|}{\|w_3\|} = 0.01561561843 < 1.$$

In the third example where  $x \in (0, 2)$  and  $t \in (0, 1)$ ,

$$\delta_1 = \frac{\|w_2\|}{\|w_1\|} = 0.3872983346 < 1,$$

$$\delta_2 = \frac{\|w_3\|}{\|w_2\|} = 0.2817180849 < 1,$$

$$\delta_3 = \frac{\|w_4\|}{\|w_3\|} = 0.2204792759 < 1.$$

Therefore, the convergence of analytical solutions is valid. Finally, the theoretical proofs for the analysis of convergence coincide with the computation results presented in the above figures and tables.

#### 4. CONCLUSIONS:

The proposed technique is an efficient methodology with good accuracy and convergence and a powerful tool to find approximate analytic solutions for the linear and nonlinear problems. The tests confirm the validity of a novel technique to handle current linear and nonlinear PDEs. In the future, this research can be extended to the investigation by applying this technique for more complicated problems such as systems of nonlinear PDEs.

**RESUMO**

Os testes de flexão são uma das maneiras eficazes de determinar experimentalmente os módulos de elasticidade e cisalhamento. Uma tarefa importante na implementação dos materiais compósitos em estruturas aeroespaciais é o desenvolvimento de métodos para determinar as características físico-mecânicas dos materiais. O artigo apresenta os resultados de testes de flexão de três pontos de amostras do material compósito metal-polímero GLARE. Foram estudadas as amostras constituídas por 17 camadas para as quais a dureza aparente entre camadas foi determinada de acordo com os resultados dos testes de flexão de três pontos. Foi estabelecido que, para as amostras estudadas, mecanismos de cisalhamento entre camadas são realizados quando a relação entre comprimento e espessura é menor que 10. A destruição está localizada na zona da camada central, que atende aos requisitos dos padrões de teste de feixe curto. No entanto, esses testes de GLARE são sempre acompanhados pela ocorrência de deformações plásticas significativas associadas à presença de camadas de alumínio na estrutura do material. Com o alongamento de amostras acima de 10, realiza-se um mecanismo de destruição, no qual ocorrem a separação de camadas e perda de estabilidade das camadas externas no lado comprimido da amostra. Quando o alongamento das amostras é menor que 4, nas amostras realiza-se o mecanismo de destruição de acordo com o tipo de indentação com grandes deformações não lineares. De acordo com os resultados do teste, foi determinada a dependência dos mecanismos de destruição realizados no alongamento das amostras.

**ABSTRACT**

Tests on bending are one of the effective ways to experimentally determine the elasticity and shear moduli. An important task in the implementation of composite materials in aerospace structures is the development of methods for determining the physical and mechanical characteristics of materials. The paper presents of tests for three-point bending of samples of metal-polymer composite material "GLASS-REinforced" Fibre Metal Laminate (GLARE) are presented. Examined samples, consisting of 17 layers, for which apparent interlayer strength of the results of tests on three-point bending was established by the method of "short beam". It was established that for the studied samples, interlayer shear mechanisms were realized at the ratio of dimensions of length to thickness of at least 10. Localization of fracture occurs in the area of the central layer,

which corresponds to the requirements of standards for conducting tests of the method of short beams. Nonetheless, such GLARE tests are always accompanied by the occurrence of significant plastic deformations associated with the presence of aluminum layers in the structure of the material. With the elongation of samples of more than 10, a fracture mechanism is realized in them, during which delamination and loss of stability of the outer layers on the compressed side of the sample occur. When the elongation of samples of less than 4 is implemented in samples takes place, the mechanism of destruction of indentation type with large nonlinear deformations. According to the test results, the dependence of the realised fracture mechanisms on the elongation of the samples is determined.

## АННОТАЦИЯ

Испытания на изгиб являются одним из эффективных способов экспериментального определения модулей упругости и сдвига. Важной задачей при внедрении композиционных материалов в авиакосмических конструкциях является разработка методов определения физико-механических характеристик материалов. В работе представлены результаты испытаний на трехточечный изгиб образцов металлополимерного композиционного материала GLARE. Исследованы образцы, состоящие из 17 слоев, для которых определена кажущая межслоевая прочность по результатам испытаний на трехточечный изгиб. Установлено, что для исследованных образцов реализуется механизмы межслоевого сдвига при соотношении размеров длины к толщине менее 10. Локализация разрушения происходит в зоне центрального слоя, что соответствует требованиям стандартов на проведение испытаний по методу короткой балки. Однако, такие испытания GLARE всегда сопровождаются возникновением значительных пластических деформаций, связанных с присутствием алюминиевых слоев в структуре материала. При удлинении образцов более 10 в них реализуется механизм разрушения, при котором происходит отслоение и потеря устойчивости внешних слоев на сжатой стороне образца. При удлинении образцов менее 4 в образцах реализуется механизм разрушения по типу индентирования с большими нелинейными деформациями. По результатам испытаний определена зависимость реализующихся механизмов разрушения от удлинения образцов.

**Ключевые слова:** *GLARE, трехточечный изгиб, короткая балка, механизмы разрушения, межслоевая прочность.*

## 1. INTRODUCTION:

Composite metal-polymer materials of GLARE type are promising structural materials for use in the construction of aviation vehicles (Kablov *et al.*, 2016; Podzhivotov *et al.*, 2016; Antipov *et al.*, 2018; Serebrennikova *et al.*, 2016; Topchiy *et al.*, 2019). These composite materials are laminated panels, formed by alternating thin layers of fiberglass and aluminum alloys. By comparison with metals, GLARE has increased specific strength, long-term durability, fire resistance. Examination of dependency on mechanical properties of GLARE from the parameters of the reinforcement is an important task, the solution of which is necessary for conducting the strength calculations and optimal design structures. One of the important characteristics determining the structural properties of GLARE, as well as other composite materials, is the interlayer strength.

Testing samples in three-point bending by the method of "short beam" (ASTM D2344...; Babaytsev *et al.*, 2017; GOST R 57745-2017...

2018) is one of the simplest methods for determining the interlayer strength of composite material (Vasiliev and Morozov, 2018). This method is widely used at research and development of composite structures since it does not require the use of complex experimental equipment and strain measurement. At the same time, the interlayer strength is an important parameter from the point of view of design, so it is used when formulating criteria for the strength of composite materials (Jones, 2014; Dmitriev *et al.*, 2011; Vasiliev and Morozov, 2018), and, in particular, when assessing the strength of the structures of GLARE. The occurrence of interlaminar cracks can lead to a reduction in carrier capacity element designs and, subsequently, to their degradation, e.g., by the mechanism of local loss resistance (Remmers and De Borst, 2011; Alekseev *et al.*, 2019; Kachanov, 2012; Sevryukova *et al.*, 2012; Lapidus and Abramov, 2018).

Though, such a simple method as a test to three-point bending contains certain deficiencies associated, in the first place, with the fact that

when these tests in samples are implemented in a complex stress state, there arise not only the tensions of the interlayer shift but also tensile/compressive stress, leading to errors in determining characteristics of material (Vasiliev and Morozov, 2018). The complexity that arises when testing samples for interlayer shear, in addition to the indicated errors associated with the inhomogeneous stress state of the samples, also lies in the fact that interlayer strength determined in the tests is not a material constant, but depends on the distance between supports. This problem is known and for ordinary composite materials (Wisnom, 1991; Xie, and Adams, 1995; Li *et al.*, 1999; Ossipyan *et al.*, 2004; Privalko *et al.*, 2005; Abali *et al.*, 2013) and for metal-polymer composites (Hinz *et al.*, 2005; Hinz *et al.*, 2009; Polilov and Tatus, 2012; Lin *et al.*, 2018; Li *et al.*, 2018; Jakubczak *et al.*, 2018; Lin *et al.*, 2019), and it is explained by the decrease of tangential stresses for working short samples (by the standards relative elongation of the samples should be 6 – 11), in comparison with the classical models of beams, which assume a constant value of the shear force and, accordingly, constant values of shear stresses (accurate to the sign) along the length of the sample. Therefore, the use of the usual ratio for estimating the shear stresses acting in a beam using the Equation 1 (ASTM D2344...) leads to an increase in the seeming interlayer strength of the material. Moreover, the effect of the length of sample on the results of tests of the interlayer strength is explained by 1) concentration of stress near the poles, for the exclusion of which special tooling is applied (Podzhivotov *et al.*, 2016; Antipov *et al.*, 2018;) 2) a statistical dependence of durability on sizes of the sample (Wisnom, 1991), 3) the occurrence of interlayer cracks outside of the neutral axis of the sample (Li *et al.*, 1999) and 4) specific dependence of the interlayer strength on parameters of mechanics of fracture (Polilov and Tatus, 2012).

In recent years there was a large amount of work, in which ways of finding the interlayer strength of metal-polymer composites were examined, according to the method of "short beam" (Lin *et al.*, 2018; Hinz *et al.*, 2005; Lin *et al.*, 2019; Hinz *et al.*, 2009; Li *et al.*, 2018; Jakubczak *et al.*, 2018; Polilov and Tatus, 2012). In GLARE, the destruction of the interlayer shear can occur both at the boundary of the contact metal and within the composite layers. In the first case, in fact, according to the results of tests defined by adhesive strength of the contact metal/composite with shear, and in the second – interlayer strength inside the composite layer. Consequently, in tests,

it is possible to determine only the characteristic that is of less value. An additional feature, which arises when testing GLARE samples by "short beam" method, is the plasticity of aluminum layers, which leads to a substantially nonlinear diagram of load-displacement, which, however, is not a hindrance to use estimates of tangential stresses in classical Equation 1, which is valid for any type of material, both elastic and plastic (Vladimirov, 2016; Antipov *et al.*, 2017). Thus, the main object of studies using GLARE is determining the degree of the error, which is realized when using the method of "short beams" by relation to more accurate, but, and more labor-intensive methods of testing. In particular, in this study, the effect of dimensions (elongation) of samples on the fracture mechanisms realized in the GLARE tests was examined.

## 2. MATERIALS AND METHODS:

For test samples with GLARE structure, 9/8 with unidirectional circuit reinforcing composite layers were made (Figure 1, Figure 2 a). The thickness of the samples was 5.5 mm, the width was 7 mm, and the length was 20-170 mm. The thicknesses of layers of fiberglass and aluminum alloy were ~ 0.32 mm. As a substitute for fiberglass, basalt fiber can be used in the manufacture of the test sample. According to its mechanical characteristics, continuous basalt fiber occupies an intermediate position between fiberglass and carbon fibers at a relatively low price. This makes this product extremely attractive for consumers for whom there are restrictions on the entry price, but at the same time, high mechanical properties are important. Selection of said structure samples is due, firstly, to the available equipment and diameter poles in the test machine, which does not allow testing too short samples and using 17 – layered GLARE, with thickness 5.5 mm, enables testing of samples of length 25-55 mm (i.e., there is an extension of 5-10, which corresponds to standard requirements) on existing supports.

Secondly, the selection of unidirectional structure of reinforcement allows to reduce the likelihood of formation of the bundles within the composite layers and, therefore, allows to evaluate the interlayer strength of the contact aluminum/composite. Using any other reinforcement schemes would lead to primary delamination at the most weakened internal boundaries between the layers of fiberglass with different directions of reinforcement. With this in process operation, it was assumed that the initial interlayer strength of the composite layers is

known, or can be determined by standard methods.

The third factor influencing the selection of the scheme of reinforcement in samples is the need to localize interlaminar cracks on boundaries by maximally closely spaced to the neutral axis of the sample. It is important to note that multilayer cracks in GLARE, even if they pass through the center of the sample, always turn out to be shifted by half the thickness of the metal layer located on the neutral line. Thus, the use of samples of large thickness allows to reduce the relative displacement of cracks from the neutral axis, and, therefore, to reduce the calculation errors of the standard Equation 1, which gives accurate values only in case of the central location of an interlayer crack (Equation 2).

Where  $P$  is the effective load,  $b$ ,  $h$  are the width and thickness of the sample.

Tests were carried out on the set Instron 5969 (Figure 2b) with lower supports of 5 mm diameter and a top support diameter of 10 mm. The test speed was 1 mm/min. Tests stopped at the decrease of the load more than 50% of the maximum. The test results were processed on the basis of Equation 1 in accordance with which the apparent (conditional) interlayer strength was determined.

Three-point bending tests were conducted in accordance with ASTM D2344. In the test the specimens were placed symmetrically on the supports and loaded by the loading nose of testing machine at the center. Deflections in the center of specimens for the prescribed loading level were registered in the tests. Corresponding load-deflection curves were plotted and used for the evaluation of the load-bearing capacity and interlaminar shear strength of specimens with different length.

### 3. RESULTS AND DISCUSSION:

According to the test results, it was established that the interlayer shift could be realized in samples with elongation of not more than eight and not less than 4.5. A typical mechanism of destruction can be well observed in the course of the test on lateral ends of all the samples (Figure 3a), but after removing the load, interlayer cracks were well distinguishable only in samples with elongation over 6 (Figure 3b). For samples with elongation of more than 10, the fracture mechanism changed. For such samples, detachment and loss of stability of the metal layer were realized in the compressed area of the sample near the support (Figure 4). For a very

short sample with elongation, less than 4 took place wrinkling of the samples, i.e., took place the failure mechanism with large transverse strains – "indentation" (Figure 5).

The characteristic diagrams of load-displacement for GLARE samples are presented in Figure 6. We can see that the given sample at a load above 1000 N chart becomes nonlinear, which can be explained by appearance plastic deformations in the layers of aluminum. With the destruction and start of an interlayer crack, a sharp drop in load occurs, which can be explained by a decrease in bending stiffness of the sample (Xie and Adams, 1995).

The dependence of breaking load on the distance between the supports obtained in the tests is presented in Figure 7. These points indicate the experimental data and the lines show theoretical approximation by the relations given below. Firstly, it follows from the obtained results that the bearing capacity of the sample decreases with increasing distance between the supports, which qualitatively corresponds to classical solutions from the theory of resistance of materials. In particular, reduction of the breaking load may be attributed to the assumption that there is a certain critical value of compressive stress, leading to detachment of the upper metal layer (as in Figure 4). The level of stress in this layer due to its small thickness can be considered as constant, and it can be found by classical beam theory. Hence, at the time of destruction, there is the Equation 3.

From this follows the estimate for maximum load (Equation 4). Where all values are known, except for critical stresses, the value of which was selected to describe the available experimental data  $\bar{\sigma} = 1020 \text{ MPa}$ . The recorded estimate (Equation 4) is qualitative and approximate, though, it shows that the maximum load in the three-point bend is inversely proportional to the elongation of the sample Equation 5 for elongations greater than 10, and this dependence is confirmed by experiment. For smaller values of elongation, this law does not work, and the dependence becomes different – the mechanism of destruction is changed to interlayer shift at the center of the sample (Figure 3). The implementation of such a mechanism is an objective of the tests. Nonetheless, it can be seen from Figure 7 that the maximum load during the interlayer shear is also dependent on the distance between the supports. This effect is known for composite materials (as it was noted above), but it is involved in contradiction with the classical solution of theory resistance materials with a

three-point bending shearing force constant on the right and left of the applied load and, consequently, are tangent strains change in an analogous manner along the length of the sample and are not dependent on this length. Apparently, in the experiment, this was not observed.

To describe the resulting dependence and for the evaluation of true interlayer strength, it is proposed to use a modified solution of the problem of three-point bending, which may be obtained in the framework model beams, built under gradient theory of elasticity (Babaytsev *and* Zotov, 2019; Lurie *and* Solyaev, 2018; Lurie *et al.*, 2018; Berezovskii *et al.*, 2015). This dependence is determined by the following relationship (Equation 6). Where –  $\tau_0$  is true interlayer strength, and the parameter  $d$  is the scale parameter of the problem, it has the dimension of length and, generally speaking, its value should be correlated with the diameter of bearings, which are used in the tests, in particular for very thin supports ( $d \sim 0$ ) is the solution (Equation 6) goes to the classical solution (Equation 2). To describe the experimental data, values of the indicated solution parameters (Equation 5) were selected, and they amounted to:

– True interlayer strength  $\tau_0 = 60.4$  MPa,

– Scale parameter –  $d = 2.7$  mm (that is, approximately, the radius of the lower supports in the area where the destruction takes place).

The obtained dependence is presented in Figure 7 by a solid line. It can be seen that in case of the small extension of samples and with the mechanism of destruction of interlayer shear, the solution (Equation 6) better describes the experimental data in comparison with the solution (Equation 4), as well as, obviously, and by comparison with classic solution, which requires independence of carrier load from a distance between the supports during the interlayer shear. The load corresponding to the constant (true) interlayer strength of 60.4 MPa is presented by the horizontal dashed line in Figure 7. The dependence of the apparent interlayer strength on the distance between the supports can be found via a combination of Equation 2 and Equation 6 in the following form (Equation 7).

This dependence is presented in Figure 8 (solid line). The points on this figure represent the experimental data obtained by processing the results of the tests (Figure 7) with the use of Equation 2. The horizontal dotted line is the calculated true interlayer strength. The deviation of relation (Equation 7) from the experiment for the shortest samples may be caused by the change in

the mechanism of their destruction. As it was said, large transverse inelastic deformations occur in such samples upon destruction.

The results of tests of GLARE samples of various elongations for three-point bending were demonstrated.

#### 4. CONCLUSIONS:

In the work, the “short beam” method was analyzed in order to determine the elasticity characteristics of composite materials, which allow to implement a program for determining the complex of elasticity characteristics of composite materials necessary for structural analysis according to the technical theory, and can be used in the development and improvement of standards. In these tests, the samples with a large number of layers and with unidirectional reinforcement schemes were used, which allowed reducing the experimental error when using standard equipment. According to the test results, the dependence of the realized fracture mechanisms on the elongation of the samples was established.

Obtained estimation of interlayer strength for GLARE  $\sim 60$  MPa, which corresponds to a typical level of interlayer strength of polymer composite materials, but in the tests, destruction took place on the border of the contact metal and composite layers, which allows us to state that the found value of interlayer strength is the characteristic of metal/composite contact, as it is realized in GLARE.

**RESUMO**

Motores de foguete elétricos são amplamente utilizados em tecnologia espacial. Além disso, atualmente, os motores de propulsão elétricos também são usados como motores de propulsão principais para voos no espaço interplanetário. Nas naves espaciais modernas, os seguintes tipos dos motores de propulsão elétricos são usados principalmente: motores de plasma estacionários e motores de íons com grades. Ao usar esses motores como motores de propulsão principais, é importante aumentar a potência total para obter a tração necessária e o impulso específico. Com o aumento da potência total, o volume da câmara de descarga aumenta, o que leva a dificuldades tecnológicas na fabricação de câmaras de descarga a partir de materiais cerâmicos. Portanto, a tarefa de encontrar alternativas aos materiais cerâmicos é relevante e necessária no desenvolvimento de motores de íons de alta frequência. O artigo discute a criação de um material compósito à base de materiais de tecido de quartzo e um aglutinante de silício orgânico como precursor preenchido com nitreto de silício para a fabricação de uma câmara de descarga de gás do motor de íons de alta frequência. Por análise termogravimétrica, selecionamos um aglutinante termo-reativo que atende aos requisitos de resistência à vibração e permeabilidade eletromagnética da câmara de descarga de gás na faixa de megahertz. Com base nesse aglutinante, preenchido com pó de nitreto de silício, reforçado com material de tecido de quartzo, foi feita a câmara de descarga de gás. O produto resultante foi testado como parte do motor de propulsão elétrico de laboratório com um diâmetro de 100 mm e uma potência de 200W.

**ABSTRACT**

Electric rocket engines are widely used in space technology. Furthermore, at present, electric propulsion engines are also used as mid-flight engines for flights in interplanetary space. On modern spacecraft, the following types of electric propulsion are mostly used: SPT and grid ion thruster. When using these engines as sustainers, it is important is to increase the total power for obtaining the required thrust and specific impulse. With an increase in total power, the volume of the discharge chamber increases, which leads to technological difficulties in the manufacture of discharge chambers from ceramic materials. Thus, the task of finding alternative ceramic materials is relevant and necessary in the development of high-frequency ion thrusters. The article discusses the issues of creating a composite material based on woven quartz materials and organosilicon binder as a precursor

filled with silicon nitride for the manufacture of gas discharge chamber (GDC) of high-frequency ion thruster (RFIT). By thermos-gravimetric analysis, a thermosetting binder, which meets the requirements of vibration resistance and electromagnetic permeability of GDC in the megahertz range, was selected. Based on the binder filled with silicon nitride powder, reinforced by quartz woven fabrics, manufactured GDC. The resulting product was tested as part of the laboratory electric propulsion device with a diameter of 100 mm and power of 200W.

## АННОТАЦИЯ

Электрические ракетные двигатели нашли широкое применение в космической технике. Также в настоящее время, ЭРД применяются и как маршевые двигатели для полетов в межпланетном пространстве. На современных космических аппаратах в основном используются следующие типы ЭРД: СПД и сеточные ионные двигатели. При использовании данных двигателей в качестве маршевых, важным является увеличение суммарной мощности для получения необходимой тяги и удельного импульса. При увеличении суммарной мощности объем разрядной камеры увеличивается, что приводит к технологическим трудностям при изготовлении разрядных камер из керамических материалов. Поэтому задача поиска альтернативных керамическим материалам является актуальной и необходимой при разработке высокочастотных ионных двигателей. В работе обсуждаются вопросы по созданию композиционного материала на основе тканых кварцевых материалов и кремнийорганического связующего в качестве прекурсора наполненного нитридом кремния, для изготовления газоразрядной камеры (ГРК) высокочастотного ионного двигателя (ВЧИД). Путем термогравиметрического анализа подобрали термореактивное связующее, отвечающее требованиям вибростойкости и электромагнитной проницаемости ГРК в мегагерцовом диапазоне. На основе данного связующего, наполненного порошком нитрида кремния, армированного кварцевым тканым материалом, изготовили ГРК. Полученное изделие прошло испытания в составе лабораторного ЭРД диаметром 100 мм, мощностью 200Вт.

**Ключевые слова:** *керамика, кремнийорганические смолы, композиционные материалы, электроракетные двигатели, газоразрядная камера.*

## 1. INTRODUCTION:

Electric rocket engines are extensively used in space technology. These types of engines, the main principle of which is ionization and acceleration of working substance, are used to stabilize and correct the position of spacecraft in orbit (Antropov *et al.*, 2002; Gorshkov *et al.*, 2008; Khartov *et al.*, 2013; Loeb, 2015; Orlov *et al.*, 2001; Rabinsky *et al.*, 2016a; Sitnikov, 2017). Also, at present, the electric propulsion engines are used as mid-flight engines for flights in interplanetary space.

On modern spacecraft, the following types of electric propulsion are mainly used: SPT and grid ion engines. The principles of their work and the design of these types are different. The acceleration and ionization of the working fluid in the SPT is carried out in the discharge channel, while the processes of ionization and acceleration are separated in grid ion thruster. Separation of the processes of ionization and acceleration makes it possible to obtain a specific impulse of up to 50,000 s, which exceeds the maximum specific impulse of SPT (about 20,000 s).

One of the types of grid ion thrusters is RFIT. The principle of operation of this engine is

based on ionization by the electromagnetic field of the working fluid (xenon) in the discharge chamber of the engine. The acceleration of ions occurs in the ion-optical system. The schematic diagram of the engine is presented in Figure 1.

For this kind of engine, the electromagnetic properties of the material of the walls of the discharge chamber are important. Presently, alumina-based ceramics are used as the material, and silicon nitride-based ceramics are also used in laboratory samples. These ceramic materials provide required radio transparency at frequencies from 500 kHz to 2 MHz and higher. The diameter of present experimental chambers reaches 500 mm, with wall thicknesses up to 8 mm (Lurie *et al.*, 2011; Formalev *et al.*, 2015; Pogodin *et al.*, 2016; Poliakov *et al.*, 2016; Ripetsky *et al.*, 2016; Rabinsky *et al.*, 2016b; Skvortsov and Karizin, 2012; Pogodin *et al.*, 2019). It is worth noting that when using ceramic materials, the question arises about their strength qualities, especially at the stage of launching a spacecraft into operational orbit.

It is also worth mentioning that when using these engines as marching, it is important to increase the total power to obtain the necessary

thrust and specific impulse. With an increase in the total power, the volume of the discharge chamber increases, which leads to technological difficulties in the manufacture of discharge chambers from ceramic materials. All this, together, makes the task of finding alternatives to ceramic materials appropriate and necessary in the development of high-frequency ion engines.

Earlier, GDC was obtained based on polymethylphenylsiloxane rubber modified with terminal vinyl groups and filled with silicon nitride by molding. The main drawback of the material used was its low heat resistance, limited by the temperature of 370°C at a residual pressure of 10-5 Pa. Taking into account the requirements for heat resistance, the binder was advanced by using MQ resins and stabilising the main polymer chain. Hence, it was possible to increase the heat resistance of the GDC material to 410°C. As a result of the tests, and it was found that with a diameter of GDC 100 mm, the material of the chamber fully met all the requirements for nodes RFIT. Nonetheless, an increase in specific capacities during optimization of RFIT design leads to the appearance of local sections of short-term heating of the gas distribution system to a value of 450°C and higher. As a result, there was a need to create a radio transparent, vibration-resistant material for GDC with increased (up to 600 °C ) heat resistance.

To accomplish this task, the authors revised the concept of composite material for the manufacture of gas distribution systems for promising RFIT (Golushko and Semisalov, 2015; Pintossi *et al.*, 2019). Despite the high resistance of silicones to heat, among other polymers, it is limited by temperatures of the order of 400-420 °C. Organic-silicon polymers in the composition of GRC, compensated for vibration loads at low temperatures, due to the low glass transition temperature. Stiff requirements for heat resistance to the binder forced to continue the search for an alternative material from the class of organic-silicon polymers operating at temperatures up to 800 °C . With complete loss of elasticity, some organosilicon polymers (for example, thermostable net siloxanes (Voronkov *et al.*, 1976; Sevryukova *et al.*, 2012; Andrianov and Sokolov, 1995) allow the GDC material to retain its electrical insulating properties, dielectric constant, and low dielectric loss tangent at temperatures up to 800 °C and higher. The densely reticulated structure of polyorganosiloxanes is characterized by low mass loss after pyrolysis of the binder and high yield of ceramo-forming residue. Therefore, composite materials based on them are characterized by high

heat resistance and can withstand repeated heating in an oxidizing environment up to 550 ... 600 °C. Composite materials based on them can work up to 1000 °C. For cross-linked polymers, the main proportion falls on the main polymer chain, represented by silicon and oxygen atoms. Correspondingly, the proportion of organic framing can be less than 20% of the mass.

The most optimal compound is methylphenylcyclospiroxiloxane (Figure 2). A distinctive feature of this oligomer is the curing mechanism by the polycondensation reaction without the release of low molecular weight substances. The use of this product is difficult due to the complexity of its synthesis by heterocondensation of silicon tetrachloride and methyl phenylsilandiol in the presence of pyridine (Andrianov *et al.*, 1978; Tkachev *et al.*, 2018).

An alternative way to obtain methylphenylcyclospiroxiloxane is the cohydrolysis of tetramethoxysilane and methylphenyl dimethoxysilane (Efremova *et al.*, 2014). Though, as a result, a low molecular weight product is formed with terminal methoxyl groups, and, as is typical for the polycondensation reaction, further molecular weight growth is difficult due to the loss of reactivity of terminal functional groups. If dysfunctional methylphenyldimethoxysilane is replaced by trifunctional vinyltrimethoxysilane, the molecular weight will increase while preserving solubility according to the critical point and Flory gelation (Florry, 1953). To increase the conversion rate by functional groups is desirable to use a polycondensation catalyst when curing the composition. Similar results were given in (Antufev *et al.*, 2019; Alekseev *et al.*, 2019; Nikitin *et al.*, 2019a; Rabinskiy and Tushavina, 2019; Umbetov *et al.*, 2017; Nikitin *et al.*, 2019b).

Since cross-linked polyorganosiloxanes, thermostable materials, are not characterized by good elastic deformation, reinforcement with woven materials is used to maintain vibration stability. According to the principle, the similar is combined with the similar, the most suitable are quartz fibers, which are characterized by a low value of the coefficient of thermal expansion, high dielectric properties and heat resistance up to 1200 °C.

## 2. MATERIALS AND METHODS:

The starting polymer was obtained by partial cohydrolysis of tetramethoxysilane methyltrimethoxysilane, vinyltrimethoxysilane, and γ-

aminopropyltrimethoxysilane, the finished product was 22-25% solution in acetonitrile, with medium viscosity molecular weight of 2700-3500 g/mol. As a reinforcing filler, quartz fabric material of TS-8/3-K brand, manufactured by NPO Fiberglass, was used (Fouquet *et al.*, 2015; Herbert *et al.*, 2009).

Silicon nitride for the filling was obtained in the SHS process by nitriding silicon powder, and the material was characterized by a specific surface of 10 m<sup>2</sup>/g. The fibrous structure of the  $\alpha$  and  $\beta$  phases of silicon nitride crystals. Crystal size  $D_{50} = 5 \mu\text{m}$ .

The pre-preg was prepared by mixing a colloidal solution of the raw polymer and silicon nitride powder; the proportion of silicon nitride was 60 wt%, relative to the binder and subsequent impregnation of silica fiber" (Dimitrakellis and Gogolides, 2018; Mansour *et al.*, 2019). The composite material was solidified at 200 °C and residual pressure of 1–3 mm Hg., tetrabutoxy titanium was used as a curing catalyst, the curing process was carried out for 2 hours. The final processing of the composite GDC material was carried out at 800°C in argon (Andrianov and Sokolov, 1995). The pyrolysis process was carried out in argon by heating to 800 degrees. Celsius at a speed of 10 degrees per minute.

The structural transformations occurring during heating of materials were studied by synchronous thermal analysis using the STA 449 F3 Jupiter device from NETZSCH (Germany) (Figure 3) in differential scanning calorimetry (DSC) mode together with thermogravimetric analysis (TGA) mode.

The samples were heated to 900°C in open crucibles from Al<sub>2</sub>O<sub>3</sub> with a volume of 0.085 ml at linearly increasing furnace temperature at a rate of 10°C/min. The crucibles were placed in cylindrical recesses of the upper part of the DSC/TG sensor made of Pt-Rh alloy. The argon flow rate through the measuring cell (sample and standard) during the experiment remained constant at 50 ml/min. A vacant crucible was used as a standard. The sample and reference temperatures were measured using built-in S-type thermocouples made of Pt-Rh alloys. The temperature measurement accuracy was  $\pm 0.3$  °C. The sample weight change was recorded with precision of 1  $\mu\text{g}$ . The isothermal balance drift over the entire temperature range was not greater than 10  $\mu\text{g/h}$ . Data collection and calculations, as well as device operation control, were made using the NETZSCH Proteus Software (Germany) software operating under the MS-Windows system.

Operational tests of prototypes of RFIT gas

distribution system with a diameter of 100 mm were carried out on a 0.4 m<sup>3</sup> vacuum test bench (Figure 4). The pumping system of the stand provided a dynamic vacuum of 10 –3 Pa at xenon flow rates of up to 0.65 mg/s.

### 3. RESULTS AND DISCUSSION:

The pyrolysis process was accompanied by the thermolysis of methyl, vinyl, substituents at silicon atom. As a result of pyrolysis, amorphous silicon oxide was formed. The yield of pyrolysis residue was about 80%. Losses of mass up to 400°C can be associated with the condensation of terminal methoxyl groups, with the release of methanol. In this area, the molecular weight increased slightly. The loss of mass above 400°C was due to the initiation of the process of thermal degradation of framing of the main polymer chain, primarily aminopropyl and vinyl substituents at silicon atom. Hence, processes that proceed up to 400°C can be associated with the progress of reaction along with unreached functional groups, the telomerization reaction, the intramolecular rearrangement of macromolecules, and removal of low boiling substances. Figure 5 displays graphs of DTA polymer filled with Si<sub>3</sub>N<sub>4</sub> 60% by weight in argon.

The heat resistance of the obtained composite material filled with Si<sub>3</sub>N<sub>4</sub> 60 wt% was somewhat higher. As can be seen from the diagram in Figure 6, a slight drift of the mass loss curve on the isotherm at 800°C is observed, which is associated with the hydrolysis of the filler, silicon nitride, and the release of ammonia, which was experimentally established. During the hydrolysis of silicon nitride, an amorphous oxynitride phase forms, which reacts with the pyrolysis residue of polymer binder (Figure 7).

Despite the loss of flexibility inherent in elastomers, the tested material did not significantly affect the performance of GDC. The introduction of quartz fibers made it possible to increase the vibration resistance of the obtained chamber by 50% compared to the ceramic counterpart.

The resulting composite material is characterized by the following properties:

- Shore hardness –85 to 90 (scale D);
- density –1.65 to 1.67 g / cm<sup>3</sup>;
- stress rupture at elongation for fibers – based on tissue 1000 kgf;
- tensile strength for fibers – Warp and weft 550 kgf;
- volumetric shrinkage after curing: 3 to 4%;

- the temperature coefficient of linear expansion:  $1.0$  to  $1 \cdot 10^{-3} \text{K}^{-1}$ ;
- electrical strength:  $15$  to  $20 \text{ kV / mm}$ ;
- dielectric loss tangent:  $0.2 \%$  to  $0.02 \%$ .

#### 4. CONCLUSIONS:

In the outline of the work carried out, the vacuum temperature stability of densely cross-linked polyorganosilaxane obtained by the cohydrolysis of tetramethoxysilane, vinyltrimethoxysilane,  $\gamma$ -aminopropyltrimethoxysilane was studied to create a polymer-ceramic composite. The resulting material, combined with the filling of quartz fibers and silicon nitride, ensured the required electrophysical and operational characteristics for RFIT (radio transparency, manufacturability, vibration resistance and other).

It was demonstrated that the studied material is characterized by high heat resistance. Silicon nitride obtained by SHS is characterized by a small fraction of free nitrogen, which is replaced by a hydroxyl group during hydrolysis. Therefore, during heating, the formation of a mixed oxynitride phase can be observed due to the interaction of silicon nitride and amorphous silicon oxide.

#### RESUMO

Como os recursos de saúde são limitados, condições de baixa renda exigem desenvolvimento tecnológico acessível. O projeto e a análise são um método colorimétrico de baixo custo para monitoramento diagnóstico diabético não invasivo por detecção de glicose da saliva e do sangue discutido, onde um novo composto (HAZM) foi preparado por meio de uma reação 4-aminoantipirina com 1-fenil-2-metil-5-pirazolon; este composto sintético foi analisado pelas técnicas de FTIR, <sup>1</sup>HNMR e <sup>13</sup>CNMR. As amostras foram processadas e analisadas utilizando o equipamento de produção usando a reação das enzimas glicose oxidase (GO) e peroxidase (PO) com (HAZM); dê ao método a capacidade de calcular o nível de glicose em menos de 15 segundos com precisão. A inclinação da curva de calibração é igual a 0,0026,  $\epsilon = 468,26$  e sensível a Sandel é igual a 0,384 mg/dL, para quantificar as concentrações salivares de glicose e o sangue (5-500 mg / dL) a 423 nm. Atingir um limite de detecção de 0,421 mg/dL, onde 5 % CV a (n = 3). Porque os testes HAZM foram realizados de acordo com um método de kit, que reflete os valores médios do kit (101,35  $\pm$  3,647 mg/dL) e os resultados do HAZM (104,41  $\pm$  4,951 mg / dL) com viés positivo de 3,1 mg / dL no sangue. Comparando os níveis médios de kit e glicose HAZM na saliva, 99,48  $\pm$  1,26 e 100,97  $\pm$  2,38 mg/dL, respectivamente, mostram viés positivo de 1,5 mg/dL para o processo do kit. Os resultados do uso desse método para medir glicose em amostras de sangue e saliva indicam que ele é eficaz, pois oferece resultados precisos e baratos, em comparação com outras técnicas comerciais.

#### ABSTRACT

Because health resources are limited, low-income conditions demand affordable technological development. The design and analysis is a low-cost colorimetric method for non-invasive diabetic diagnostic monitoring by glucose detection of the saliva and blood discussed, where a new compound (HAZM) was prepared through a reaction 4-aminoantipyrine with 1-phenyl-2-methyl-5-pyrazolon; FTIR, <sup>1</sup>HNMR, and <sup>13</sup>CNMR diagnosed for this synthetic compound. Samples have been processed and analyzed using the production equipment using glucose oxidase (GO) and peroxidase (PO) enzymes reaction with (HAZM); give the method the ability to calculate glucose level in less than 15 seconds accurately. The slope of the calibration curve is equal to 0.0026,  $\epsilon = 468.26$ , and Sandel sensitive equals 0.384 mg/dL, to quantify the glucose salivary concentrations and blood (5-500 mg/dL) at 423 nm. Achieve a detection limit of 0.421 mg/dL where 5 % CV to (n = 3). Because HAZM tests performed according to a kit method, which reflects the mean kit values (101.35  $\pm$  3.647 mg/dL) and the results of HAZM (104.41  $\pm$  4.951 mg/dL) with 3.1 mg/dL positive bias in blood. Comparing the mean kit and HAZM glucose levels in saliva, 99.48  $\pm$  1.26, and 100.97  $\pm$  2.38 mg/dL, respectively, shows 1.5 mg/dL positive bias for the kit process. Results from the use of this method for measuring glucose in blood and saliva samples indicate that it is effective, as it offers accurate, and its cheap results compared to other

## الخلاصة

لأن الموارد الصحية محدودة ، تتطلب الظروف منخفضة الدخل تطوراً تكنولوجياً ميسور التكلفة. التصميم والتحليل هو طريقة قياس الألوان منخفضة التكلفة لرصد تشخيص السكري عن طريق الكشف عن الجلوكوز في اللعاب والدم الذي تمت مناقشته ، حيث تم تحضير مركب جديد (حازم) من خلال تفاعل 4-امينو انتي بايرين مع 2-1-فينيل ميثيل 5 بيرازولون. تم تشخيص هذا المركب الاصطناعي بواسطة FTIR و  $^1\text{H}$ NMR و  $^{13}\text{C}$ NMR. تمت معالجة العينات وتحليلها باستخدام معدات الإنتاج باستخدام تفاعل إنزيمات الجلوكوز أوكسيداز (GO) وإنزيم البيروكسيداز (PO) مع (HAZM) ؛ امنح الطريقة القدرة على حساب مستوى الجلوكوز في أقل من 15 ثانية بدقة. يساوي انحدار منحنى المعايرة  $0.0026$  ،  $\epsilon = 468.26$  ، وحساسية ساندل تساوي  $0.384$  مجم / ديسيلتر ، لتحديد تركيزات الجلوكوز اللعابية والدم ( $500\text{--}5$  مجم / ديسيلتر) عند  $423$  نانومتر. تحقيق حد كشف  $0.421$  مجم / ديسيلتر حيث تكون  $5\%$  من السيرة الذاتية على ( $n = 3$ ). لأن اختبارات (حازم) تم إجراؤها وفقاً لطريقة عدة ، والتي تعكس متوسط قيم المجموعة ( $101.35 \pm 3.647$  مجم / ديسيلتر) ونتائج (حازم) ( $104.41 \pm 4.951$ ) مع  $3.1$  ملجم / ديسيلتر تحيز إيجابي في الدم. بمقارنة متوسط المجموعة ومستويات الجلوكوز (حازم) في اللعاب ،  $1.26 \pm 99.48$  ، و  $2.38 \pm 100.97$  مجم / ديسيلتر ، على التوالي ، يظهر انحياز إيجابي  $1.5$  مجم / ديسيلتر لعملية المجموعة. تشير نتائج استخدام هذه الطريقة لقياس الجلوكوز في عينات الدم واللعاب إلى أنها فعالة ، لأنها تقدم نتائج دقيقة ورخيصة مقارنة بالتقنيات التجارية الأخرى.

**الكلمات المفتاحية:** مركب آزو ، طريقة طيفية ، الجلوكوز ، الدم واللعاب.

## 1. INTRODUCTION:

Diabetes was the leading cause of impairment and death due to higher blood glucose (Deshpande, Harris-Hayes, and Schootman, 2008). The accepted standard level of the blood glucose range is 87.88 to 123.78 mg/dL (Owens, Dada, Cyrus, Adedoyin, and Adunlin, 2020). Blood glucose control levels are essential in the prevention of severe chronic disease complications (Mian, Hermayer, and Jenkins, 2019). In general, coupling enzymatic reactions in glucose oxidase (GO) and peroxidase (PO) because of the advantages of variables such as substrate specificity, reaction rate, pH, products inhibition, quality, and cost of enzymes have been taken into account amongst the various detection techniques (Bankar, Bule, Singhal, and Ananthanarayan, 2009). Glucose coupling enzymatisation begins with GO oxidation, producing by-products of  $\text{H}_2\text{O}_2$  where used by PO to oxidize the aromatic organic component by electron donor substrate (EDS) (Galant, Kaufman, and Wilson, 2015). It is possible to estimate glucose levels in the blood or saliva by changing the absorbance intensity of the unique interaction with the responsible enzymes by varying the response speed according to each concentration (Villamena, 2017); such as Trinder's method (Abrera, Sützl, and Haltrich, 2020). Azo compounds may interact with the PO enzyme to indicate that the blood sugar level is measured (Sarkar *et al.*, 2020).

In this research, a new chemical azo compound, (Z)-1,5-dimethyl-4-((1-methyl-3-oxo-2-phenyl-2,3-dihydro-1H-pyrazol-4-yl)diazinyl)-2-phenyl-1,2-dihydro-3H-pyrazol-3-one, which is

called (HAZM) acronym, it was prepared in a direct synthesis process, through which the concentration of glucose in blood and saliva samples was measured for several volunteers in addition to a number of patients with diabetes and a number of healthy people, depending on enzymatic reactions and a spectral technique that can be relied upon in clinical laboratories in hospitals or routine tests for people with diabetes as they are fast and inexpensive.

## 2. MATERIALS AND METHODS:

All the chemicals used in this research were highly pure. A number of spectral devices were used, such as FTIR Shimadzu measurements model 8400 Series,  $^1\text{H}$ NMR spectra BRUKER AV 400,  $^{13}\text{C}$ NMR spectra BRUKER AV 100, and Shimadzu UV-Vis Spectrophotometer Shimadzu UV-1650Pc.

### 2.1. Preparation of azo compound (HAZM):

2.0325 g from 4-aminoantipyrine (0.01 mol) was diazotized by dissolving it in 50 mL of ethanol; then, 5ml of HCl [5M] was added. The temperature was kept between 0 to 5 °C. It was slowly added a 1% solution  $\text{NaNO}_2$ , and then it was left resting for one hour (Sayhood and Mohammed, 2015a, 2015b). Later, an alkaline well-cooled solution of (1.7420 g) 1-phenyl-2-methyl-5-pyrazolon (0.01 mol) was slowly added to the diazonium salt. The mixture formed a precipitated, and it was washed with a 0.5:1 (ethanol: water) to it was recrystallized and dried after that Scheme 1 demonstrates the synthesis of (Z)-1,5-dimethyl-4-((1-methyl-3-oxo-2-phenyl-2,3-dihydro-1H-pyrazol-4-yl)diazinyl)-2-phenyl-

1,2-dihydro-3H-pyrazol-3-one (HAZM); this synthetic compound was analyzed using FTIR,  $^1\text{H}$ NMR, and  $^{13}\text{C}$ NMR, where these techniques were essential for the exact chemical structure of the synthesis compound to be decided (Balci, 2005; Karabacak *et al.*, 2014).

## 2.2. FTIR measurement:

The FTIR spectra were recorded in the region (4000-400)  $\text{cm}^{-1}$  by used 0.1 g of (HAZM), which mixed with 0.1 g KBr and ground together to form a transparent disk about 1 cm in diameter and 1 mm thick after pressing the mixture.

## 2.3. $^1\text{H}$ NMR and $^{13}\text{C}$ -NMR measurement:

10 mg of (HAZM) dissolved in pure deuterated DMSO as a solvent and tetramethylsilane as an internal standard to the analysis of  $^1\text{H}$ NMR and  $^{13}\text{C}$ -NMR spectra.

## 2.4. Preparation of (HAZM) solution with enzymes:

The preparation of the mixture was accompanied by freshly-prepared enzyme solutions. In the phosphate buffer, 0.01 M (2 mL, pH 7.6) of GO (0.25 mg) and PO (0.5 mg) were separately prepared and kept at 4 °C during experimental procedures. (2 mg) of HAZM was dissolved into ethanol with (5 mL, pH 7.6) of 0.01 M phosphate buffer. The solutions have been degaussed as well as the stability of solution changes has been monitored throughout three days with UV / VIS spectroscopy. No change was observed in the HAZM solution absorption spectrum at 423 nm (Figure 1) due to auto-oxidation or precipitation (Banham *et al.*, 2015; Najafi, 2017).

## 2.5. Preparing blood serum and saliva samples:

For the establishing of the methodologies, the Al-Najaf Center for Diabetes and Endocrine obtained both saliva and blood test. The Sample was taken under a fasting state from the volunteers. Two volunteer groups aged 18-61 years, with 94 diabetics and 22 non-diabetics. Whole blood (5 mL) has been drawn into the non-anti-coagulant vacuum tube. To facilitate coagulation, it remained still for 20 minutes. The serum was suctioned, then maintained at 4 °C after the centrifugation (10 min at 25000 cycles). Collected saliva samples 2 mL of the whole unstimulated saliva has been used to assess the salivary glucose level. The samples were then centrifuged (3 min at 25000 cycles), and glucose tests were performed on the resulting supernatant. In order to determine the connection

between blood glucose and the salivary concentration, the Center carried out simultaneous blood sampling for every volunteer.

## Ethical Consent

*"Verbal consent was taken from all participants after explaining the aims, methods, sources of funding, any possible conflicts of interest, institutional affiliations of the researcher, the anticipated benefits and potential risks of the study and the discomfort it may entail."* (Schroter, Plowman, Hutchings, and Gonzalez, 2006)

## 2.6. Determination of glucose:

In order to establish the HAZM method, a commercial Glucose Assay Kit was used to examine test samples in which a (1 mL) solution kit was added to ten  $\mu\text{L}$  of serum tests. The mixture was 20-minute incubated at 25 °C, and it is measured at 516 nm. The concentration of glucose was determined from the typical vendor curve.

In the HAZM method, a test solution consisting of phosphate buffer (0.01 mM) containing GO (0.025 pM), PO (0.05 pM), and HAZM (0.02 mM), where the final volume was (2 mL), was applied to the blood sample serum (20  $\mu\text{L}$ ). After 15 seconds, the optical density change was registered at 423 nm. The concentration of glucose was determined from the resulting calibration curve (Figure 2). In order to determine the HAZM method for evaluating the level of salivary glucose, in the testing solution, 10 $\mu\text{L}$  of a resulting supernatant has been used after drawing 0.5 mL of freshly saliva and centrifugation; and measure at 423 nm.

# 3. RESULTS AND DISCUSSION:

## 3.1. Explanation of the process:

Actual blood glucose monitoring systems are based on photometric or electrochemical techniques (Pu *et al.*, 2016). Direct glucose oxidation by GO was used to produce electrochemical sensors for personal optical measuring instruments (Zhang *et al.*, 2019). The replicability of tests, in addition to the sensitivity of electrochemical sensors to specific significant interventions, nevertheless decreases as the system time of life (Aljafery, Sayhood, Abdulridha, and Yousif, 2018). Unlike electrochemical electrode construction, it is simpler and cheaper to create photometric instruments (Al-Shirifi, Dikran, and Halboos,

2018; Halboos, Ammar Sayhood, and Ala'a Hussein, 2019). Even so, the precision of these instruments depends both on the overall performance of the technique and on the technical specifications (Hwang *et al.*, 2017).

Trinder method for measuring glucose in the blood is the first procedure based on the use of  $\text{H}_2\text{O}_2$  (GO by-product) in clinical laboratories. Still, it has not been developed by researchers to benefit from them in measuring glucose in the miniaturized personal colorimeters (Kengne, Erasmus, Levitt, and Matsha, 2017).

The spectrum of the HAZM method showed one peak at 423 nm Figure 1. HAZM's reaction to varying quantities of PO with a constant  $\text{H}_2\text{O}_2$  concentration has linear. For the tests, 2 mL of PO 5 nM was chosen, HAZM response was also linear to different amounts of  $\text{H}_2\text{O}_2$ . Consequently, PO oxidation of HAZM was coupled with GO (2.5 nM) glucose oxidation. The oxidation response of the HAZM procedure to various glucose levels was linear of 5-500 mg/dL glucose; this result is considered good if compared to previous studies (Bruen, Delaney, Florea, and Diamond, 2017; Dominguez, Orozco, Chávez, and Márquez-Lucero, 2017).

### 3.2. FTIR Analysis

Spectroscopy of the synthetic compound (HAZM) was performed using FTIR, where the analysis showed a number of peaks as shown in (Figure 3) having a wide band of  $3485\text{ cm}^{-1}$  (s) attributable for the stretching, vibration of O-H,  $\nu\text{C-H}$  aromatic at  $3157\text{ cm}^{-1}$  (m). Carbonyl group  $\nu(\text{C=O})$  stretching frequency at  $1674\text{ cm}^{-1}$  (s). Likewise the frequency at  $1537\text{ cm}^{-1}$  (w) and  $1491\text{ cm}^{-1}$  (m) corresponding to  $\nu(\text{N=N})$ .

### 3.3. $^1\text{H}$ NMR and $^{13}\text{C}$ -NMR Analysis

The following signals are shown in the deuterated DMSO solution with the tetra methylsaline internal standard:  $^1\text{H}$ NMR (Figure 4) and  $^{13}\text{C}$ -NMR (Figure 5) of the prepared azo compound (HAZM). The  $^1\text{H}$ -NMR (HAZM) spectrum has a multiplied spectrum of  $\delta$  (7.57-7.33) ppm (s, 12H, Ar) due to phenyl groups, -N-CH=(4-Aminoantipyrin) due to  $\delta$  (3.4) ppm (s, H) and =C-CH<sub>3</sub> due to  $\delta$  (2.6) ppm, -N-CH= (1-phenyl-2-methyl-5-pyrazolone) due to a multiple  $\delta$  (3.1) ppm (s, H) and =C-CH<sub>3</sub> due to  $\delta$  (2.5) ppm. The signals in  $^{13}\text{C}$ -NMR show (HAZM) were: (138-126) ppm (12C, Ar-C); 151 ppm (C=O); 31.9 ppm (C-CH<sub>3</sub>) (1-phenyl-2-methyl-5-pyrazolone) 39 ppm (N-CH<sub>3</sub>); 34.8 ppm (C-CH<sub>3</sub>) (4-aminoantipyrine), 40.3 ppm (N-CH<sub>3</sub>) 143 ppm (-C-N=N-C-).

### 3.4. Glucose measurements in blood:

The glucose levels of 116 serum samples were examined by kit and HAZM system in order to verify the relevant HAZM process. A review of results from Pearson showed a strong association ( $r > 0.95$ ) between kit and HAZM tests. The experimental (t-test) of levels of sugar blood there in samples tested using HAZM and kits approaches did not show a significant distinction between these results ( $P > 0.05$ ). Because HAZM tests were performed according to a kit method, more favorable mistakes were reported, which reflect the mean kit values ( $101.35 \pm 3.647\text{ mg/dL}$ ) and the results of HAZM ( $104.41 \pm 4.951\text{ mg/dL}$ ) with 3.1 mg/dL positive bias. This is expected to be caused by delayed glycolysis (Moutasim and Thomas, 2020).

### 3.5. Glucose measurements in saliva:

Early identification and prevention of many diseases were assisted by salivary diagnosis (Lee, Garon, and Wong, 2009). The reliance on HAZM for non-invasive control of the salivary glucose concentration has been evaluated based on the promising potential saliva application areas in personal dentistry (Olczak *et al.*, 2019), and much more crucially, the limit of detection for the HAZM method ( $0.421\text{ mg/dL}$ ). In this study, both kit and HAZM methods evaluated non-stimulated whole saliva of diabetic and non-diabetic samples. The speedy samples obtained to limit the effects of possible interference substances, particularly  $\text{C}_2\text{H}_4\text{OHCOOH}$ , where can has a significant effect in saliva pH (Kubáň, Dvořák, and Kubáň, 2019). Analysis of the data of the HAZM and the kit data for salivary glucose concentration indicated insignificant results differences ( $P > 0.05$ ). The results of diabetic and non-diabetic individuals' salivary glucose concentration were also correlated with corresponding fasting glucose level values. Comparing the mean kit and HAZM glucose levels,  $99.48 \pm 1.26$  and  $100.97 \pm 2.38\text{ mg/dL}$  respectively, show 1.5 mg/dL positive bias for kit process.

#### Conflict of Interest:

*"The authors declare that they have no conflict of interest."*

## 4. CONCLUSIONS:

The current method for blood sugar calculation and salivary samples using coupled enzyme GO and PO was based primarily on the

spectrophotometric characteristics of HAZM. It is stable and accurately calculates the glucose levels in less than 15 seconds. Taking into consideration that only the first stage in the combined enzyme assay quantification of blood glucose has also been modified in the HAZM method. It will be possible to develop this method in the near future to make it one of the techniques that are characterized by ease of dealing with it.

## 5. ACKNOWLEDGMENTS:

The authors thank and gratefully appreciate the staff of the Al-Najaf Center for Diabetes and Endocrine for their facilities to accomplish this research.

### RESUMO

Neste estudo, a voltametria cíclica (CV) é apresentada com uma técnica eletroquímica sensível para a avaliação do medicamento anticâncer Toposar (TPS). O eletrodo foi formado na superfície de um eletrodo de carbono vítreo modificado com MWCNT usando um revestimento de L-fenil alanina para se tornar o novo eletrodo em uma fórmula (PPA-MWCNT/GCE). O PPA foi polimerizado em pH 8,0, o que mostrou vantagens avançadas para o estudo e estimativa do tratamento por eletroanálise por TPS. Um grupo de fatores no eletrodo de carbono vítreo vazio foi estudado para aprimorar o trabalho do eletrodo no estudo do TPS, incluindo esses fatores (influência do pH, curva de calibração, estabilidade do eletrodo, taxa de varredura, potencial de deposição, etapa de voltagem, equilíbrio) tempo, tempo de deposição). Como resultado do desenvolvimento do eletrodo, a estabilidade do eletrodo preparado foi observada com a camada de PPA com a morfologia da camada pela análise SEM, mostrando a morfologia de PPA/GCE e MWCNTs/PPA/GCE por SEM, respectivamente. A largura do filme PPA na resposta TPS tem maior sensibilidade na superfície de MWCNTs/PPA/GCE em comparação com GCE, e reversibilidade redox aumentada com número de 8 ciclos, o CV de 5,0 nM TPS no GCE com taxas de varredura entre 50 e 400 mV·s<sup>-1</sup>. Essa reação foi prevista para um mecanismo irrevogável de eletrodo. Uma comparação foi feita entre os CVs do TPS nos MWCNTs e o eletrodo modificado pelo PPA com o GCE desencapado a pH 7,0 com uma taxa de varredura de 100 mV·s<sup>-1</sup>, a corrente de oxidação é 11,18 vezes maior que a comparável no GCE desencapado.
