In this study, cyclic voltammetry (CV) is presented with a sensitive electrochemical technique for the assessment of the anti-cancer medicine Toposar (TPS). The electrode was formed on the surface of a modified glassy carbon electrode with MWCNT using a coating of L-phenyl alanine to become the new electrode in a formula (PPA-MWCNT / GCE). PPA was polymerized at pH 8.0, which showed advanced advantages for the study and estimation of TPS electroanalysis treatment. A group of factors on the bare glassy carbon electrode were studied to enhance the electrode 's work to study TPS, including these factors (Influence of pH, calibration curve, the stability of the electrode, scan rate, deposition potential, voltage step, equilibration time, deposition time). As a result of the electrode development, the stability of the prepared electrode was observed with the PPA layer with the Morphology of the layer by the SEM analysis showing the morphology of PPA/GCE and MWCNTs/PPA/GCE by SEM, respectively. The PPA film width on TPS response has higher sensitivity on the surface of MWCNTs/PPA/GCE compared to GCE and increased redox reversibility with 8 cycles number. The CV of 5.0 nM TPS on GCE with scanning rates of between 50 and 400 mV·s<sup>-1</sup> This reaction was predicted for an irrevocable electrode mechanism. A comparison was made between the TPS CVs on the MWCNTs, and the PPA modified electrode with the bare GCE at pH 7.0 with a scan rate of 100 mV·s<sup>-1</sup>, the oxidation current is 11.18 times higher than the comparable one on the bare GCE.

**Keywords:** *Toposar, poly L-phenyl alanine, cyclic voltammetry, Sensor, MWCNT.*

## 1. INTRODUCTION:

Toposar (TPS), as a chemotherapy drug, is used for the treatment of testicular cancer, lymphomas, and small cell lung cancer (Toffoli *et al.*, 2004; Sissolak *et al.*, 2010). TPS acts by harming the DNA of the cancer cells. Topoisomerase inhibition, as well as apoptosis, causes DNA damage (Osherooff., 1989; Kovacic and Osuna., 2000).

Podophyllotoxin (PTOX) has been suggested as an anti-cancer drug for the therapy of tumor cells through blocking the tubulin polymerization, which induces the detention of cell cycle at mitosis, and stops cancer cell growth. PTOX products, including TPS, have been proposed for venereal wart and cancer therapies. One of the significant issues with this naturally extracted-plant derivative is its reservoirs (Ardalani *et al.*, 2017).

During electropolymerization, the thickness of polymer film is controlled by the number of cycles. Deposited films on surface electrodes by electropolymerization provide good homogeneity to the electrode surface. Based on the literature review, electrochemical detection of TPS, using a poly (L-phenylalanine) glassy carbon of modified electrode (PPA/GCE), has never been investigated previously. Amino acids have different functional groups, acting as the building blocks of protein structures, and allowing the adsorption mechanism to occur on electrocatalytic surfaces.

The condensation reaction of amino acids occurs when the C-terminus of one comes in proximity of the N-terminus of the other. Initially, oxygen and hydrogen atoms from the associated group of carboxyl and then hydrogen atom from the NH group of amino form a molecule of water (Andrea *et al.*, 2011).

Amino acid adsorption is essential for protein interaction with surfaces (Khan *et al.*, 1996). Generally, the electrochemical determination of medicines, using a poly L-phenylalanine (PPA) film (PPA/GCE) by electrochemical techniques, is a very selective and sensitive method. Voltammetric methods are appropriate for assessing the redox characteristics of functional medicine (Ozkan, 2012; Wang, 1998; Uslu, 2010; Dogan *et al.*, 2011).

Techniques that are applied to examine the medicine communications with DNA are as follows: UV-Visible spectrophotometry (Marky *et al.*, 1983), fluorescence spectroscopy (Jenkins *et*

*al.*, 1998; Song *et al.*, 2006), constant wavelength synchronous fluorescence spectroscopy (CW-SFS) (Garbett *et al.*, 2007), circular dichroism (Garbett *et al.*, 2007; Pasternack., 2003), spectroscopy of Raman resonance (Manfait *et al.*, 1982) and Fourier transform infrared spectroscopy (Nafisi *et al.*, 2013).

## 2. MATERIALS AND METHODS:

The devices, materials, and arrangement of Poly (L-phenylalanine) on GCE used in this work, are described in the following paragraphs:

### 2.1. Instrumentation

Voltammetric measurements were done by 797 VA (Computrace Metrohm, Switzerland). A standard three-electrode complex comprised a working electrode, which is modified, a reference electrode, Ag/AgCl with saturated KCl, a bare GCE, and a wire of platinum as an auxiliary, used in all electrochemical tests. All tests were conducted at a temperature of  $25.0 \pm 0.5$  °C. The pH meter (digital HANNA, Portugal) was used to measure the pH (Mohammed *et al.*, 2019).

### 2.2. Reagents

TPS and the required dosage of pharmaceutical form were acquired by Koçak Farma Inc. (Istanbul, Turkey). L-phenylalanine used in this study was of analytical grade, acquired from Fluka. The supporting electrolytes used here were as follows: Phosphate, Tris-HCl, and Britton Robinson buffers. All solutions were kept in the dark and utilized on a day to prevent decay. All chemicals and reagents were of analytical grade (Fluka, BDH), applied as received with no further purification. Double distilled water (DDW) was utilized during the experimental study.

### 2.3. Arrangement of Poly (L-phenylalanine) Altered GCE on multi-walled carbon nanotubes (MWCNTs)

Before the electrochemical alteration, the GCE was cleaned with a slurry of alumina of 0.3 and 0.05  $\mu\text{m}$  pore size, to a mirror-like surface, then it was rinsed with DDW. Afterward, the GCE was treated consecutively with 1:1 nitric acid: absolute ethanol, and distilled water in an ultrasonic bath for 5 min, respectively. For the electropolymerization of the L-phenylalanine on the MWCNTs/GCE, after cleaning, the GCE was deposited in 0.01 M phenylalanine solution (0.2 M

PBS, pH 8.0), formerly degassed with high purity nitrogen for 5 min. The electrode was subjected to cyclic scanning between -1.5 and 2.5 V, with a scan rate of 80 mV.s<sup>-1</sup>, using 8 cycles. A polymer of blue color on the GCE surface was formed and washed with reagent water type IV (ASTM D1193) (Daniel *et al.*, 1982); the electropolymerization mechanism is represented in Figure 1

### 3. RESULTS AND DISCUSSION:

#### 3.1.1. Voltammetric study of Toposar

The redox mechanism of TPS, a medicine for anti-cancer treatment, was investigated as a further application for bio-detection in 0.2 M PBS at pH 7, by cyclic voltammetry (CV) sweeps from -1.5 to +2.0 V, with a scan rate of 100 mV.s<sup>-1</sup>, until stable voltammograms were acquired, as presented in Figure 2. The oxidation potential was performed at 0.42 V versus Ag/AgCl/sat. KCl, following the instrument default conditions.

#### 3.1.2. Voltammetric study of Toposar

To optimize the conditions for measurement by CV technique, a cyclic voltammogram of 3.0 nM TPS in PBS at pH 7.0, studied previously (Bozal *et al.*, 2013), used as a supporting electrolyte. Table 1 shows all the parameters optimized for the measurement of TPS.

#### 3.1.3. Voltammetric study of Toposar

The influence of pH of the solution on the feedback of 3.0·10<sup>-9</sup> M TPS was tested in the pH, ranging from 4.0 to 9.0 in PBS, by CV at a scan rate of 100 mV.s<sup>-1</sup> (Figure 3-a). As pH was increasing, the peak potential switched to more negative values, at pH 9.0, and turned out unmeasurable. The linear correlation between oxidation potential and pH can be presented as Equation 1.

$$E_{pa} = -58.3 \text{ pH} + 845.8 \quad (\text{Eq. 1})$$

Where  $E_{pa}$  is expressed in mV, with  $r = 0.997$ .

The pH of the solution significantly influenced the oxidation current. The PBS at pH 7.0 was selected for the assessment of TPS with the highest peak current (Figure 3-b).

#### 3.1.4. The calibration curve of the TPS

The relation between concentrations of TPS and oxidation current was examined in serial experiments with different concentrations of TPS in PBS at pH 7.0 (Figure 4). The experiment was performed under optimal conditions, as illustrated in Table 1.

#### 3.1.5. Stability of TPS

The TPS stability was measured in 0.3 nM of TPS, in PBS at pH 7.0, by simulating measurements on the electrode and preparing a periodic assessment of readings for the same cell, as shown in Figure 5.

#### 3.2.1. Electropolymerization of PPA

The PPA film thickness is managed by the number of cycles of voltammetric scans throughout the electrochemical alteration of a GCE surface, as shown in Figure 6 in PBS at pH 8.0.

#### 3.2.2. Morphology characterized by SEM of PPA/GCE & MWCNTs/PPA/GCE

Figure-7 (a-c) and Figure-7 (d-f) show the morphology of PPA/GCE and MWCNTs/PPA/GCE by SEM, respectively.

#### 3.3.1. Impact of the PPA film width on the response of TPS

The diameter of the PPA film on the electrode surface was investigated by CV, concerning the electrochemical response of TPS. The peak currents of TPS were much depended on the thickness of the PPA film. Reduction and oxidation current peak augmented with the thickness elevation of the PPA film. At the same time, the reduction and oxidation potential were negatively and positively shifted, respectively, showing the redox reversibility of TPS was weakened with the thickness elevation of PPA. TPS has higher sensitivity and better redox reversibility; therefore, 8- cycle was chosen to control the PPA film thickness.

#### 3.3.2. The influence of pH on the polymerization of PA

The effect of pH on oxidation currents of PPA on GCE was examined. Figure 8-a shows that by increasing pH, the reduction potential shifted negatively. The increasing pH for PPA was negatively shifted for the potential related to the

current ( $I_{pa}/\mu A$ ), as shown for L-phenylalanine at pH 8.0 (Figure. 8). Therefore, pH 8.0 was selected as an optimal condition for L-phenylalanine.

### 3.3.3. Effect of pH on PPA for detection of TPS

The impact of the pH of PBS on the reaction of TPS was examined by CV. The TPS was well-behaved in PBS, as pH increased, the anodic peak potential became negative, and a good linear correlation was found in the graph of  $E_{pa}$  vs. pH in PBS, with pH ranging from 5.0 to 9.0. Equation 2 is the linear regression equation.

$$E_{pa} V = 0.5631 - 0.422 \text{ pH} \quad (\text{Eq. 2})$$

With an  $R^2 = 0.9712$ , as shown in Figure 9.

### 3.3.4. Electrochemical Oxidation of TPS at the PPA Modified Electrode

TPS oxidation potential and current can be determined on bare GCE; oxidation current is more significant than the comparable one, on the naked GCE. This demonstrated that the catalytic response happened between the PPA altered electrode and TPS. The catalytic response simplifies the relocation of an electron between the modified electrode and hydroquinone (TPS). Therefore the redox potential of TPS turned out to be simpler. PPA itself is electroinactive in the potential range from -1.5 to 2.0V (Figure10-a). Because of the high porosity of the PPA, the entire exterior area of the GC electrode is much bigger than that of bare GCE. Therefore, oxidation current elevates more clearly, more detailed in Figure10-b.

### 3.3.5. Impact of Scan Rate

The impact of the scan rate on oxidation current and the oxidation potential of TPS was examined. For this study, we documented the CV of  $5.0 \cdot 10^{-9}$  M TPS on GCE with scan rates, ranging from 50 to 400  $\text{mV} \cdot \text{s}^{-1}$  (Figure 11-a). By elevation of the scan rates, the peak potential ( $E_{pa}$ ) for the oxidation of TPS was increased. This reaction was predicted for an irrevocable electrode mechanism. The linear graph of  $I_{pa}$  as a function of  $u^{1/2}$  (Figure 11-b) demonstrates that the oxidation of TPS on the GCE was diffusion-managed. For TPS, the graph of the logarithm of the scan rate as a function of the logarithm of peak current was linear with a slope of 0.91; this amount is near the theoretical value of 1.0, which demonstrates that a standard reaction is a diffusion-managed electrode mechanism (Figure. 11-c). Equation 3 can be presented as

$$\text{Log } I_{pa} (\mu A) = 0.918 \text{ log } u (\text{s})^{-1} + 0.7696 \quad (\text{Eq. 3})$$

With a  $R^2 = 0.9506$ .

### 3.3.6. Electrochemical Oxidation of TPS at the MWCNTs-PPA Modified Electrode

A comparison was made between the CVs of TPS on MWCNTs, PPA modified electrode with that of bare GCE. The CVs on bare GCE is demonstrated in Figure 12-curve a, and on MWCNTs PPA modified electrode in Figure 12 - curve b at pH 7.0 with the scan rates of 100  $\text{mV} \cdot \text{s}^{-1}$ . The oxidation current is 11.18-fold larger than the comparable one on the bare GCE.

## 4. CONCLUSIONS:

In this work, a novel approach was presented for the creation of a new voltammetric sensor of TPS depended on MWCNTs PPA coating. Excellent sensitivity, high selectivity, and fast electron transfer were acquired for the oxidation of TPS on the PPA modified electrode. The current GC altered electrode (PPA/GCE) demonstrated a distinguished selectivity, antifouling characteristics, and sensitivity, as well as can isolate oxidation peaks for TPS, which are identical on the naked electrode. Chemically modified electrode, MWCNTs PPA is a promising sensor and has the potential to be used for drug assessment.

**RESUMO**

Os compósitos de fibra baseados em matrizes poliméricas são um componente essencial na criação da técnica robusta. Devido aos vários fatores, o design da engenharia aeroespacial deve consistir em materiais de alta durabilidade, resistência ao calor e ter outras propriedades qualitativas. Os problemas associados à destruição de compósitos de fibras foram relevantes em todas as etapas do desenvolvimento da tecnologia. A variedade de fibras de reforço e ligantes de polímero, bem como esquemas de reforço, permite controlar direccionalmente a resistência, rigidez, nível de temperatura operacional e outras propriedades dos materiais compósitos poliméricos. Este artigo discute o método de determinação experimental das propriedades mecânicas de materiais compósitos poliméricos à base de fibra de carbono, incluindo a determinação da tenacidade às fissuras entre camadas sob carga sob condições de rasgo, usando o método Direct Bonded Copper (DCB) e a tenacidade às fissuras sob condições de cisalhamento transversal usando o método End-notched flexural test (ENF) e resistência entre camadas. São apresentados os resultados dos testes de amostras de materiais compósitos poliméricos com reforço de carbono com diferentes densidades de superfície. Foi estabelecido que tais características como resistência entre camadas e resistência às fissuras são os parâmetros importantes e determinantes da durabilidade. Foi determinado que o esgotamento da durabilidade de camadas individuais do compósito nem sempre afeta o estado atual de tensão de toda a estrutura e às vezes é difícil de detectar experimentalmente, mas pode afetar significativamente o comportamento adicional do objeto em estudo, desde que a zona de fissura progrida. Foi estabelecida a resistência entre as camadas das amostras com valores experimentais variados. Os dados experimentais foram utilizados para identificar os parâmetros dos modelos de Crack Closure Technique (VVCT) e Cohezive Zone Model (CZM) utilizados para descrever o desenvolvimento de fissuras nos compósitos considerados.

**Palavras-chave:** fibra de carbono, parâmetros de resistência as fissuras, tenacidade às fissuras, resistência entre camadas, polímero.

**ABSTRACT**

Fiber composites based on polymer matrices are promising structural materials that meet high requirements for strength, reliability, durability, and hardness. Therefore, composite materials are widely used as structural materials for aerospace products. The problems associated with the destruction of fiber composites

were relevant at all stages of technology development. A variety of reinforcing fibers and polymer binders, as well as reinforcement schemes, allow directional control of strength, stiffness, level of working temperatures and other properties of polymer composite materials. This article discusses a methodology for experimental determination of the mechanical properties of carbon-based fiber-reinforced polymer composite materials, including the determination of the interlayer fracture toughness under loading under separation conditions using the double-cantilever beam method (DCB) and the fracture toughness under transverse shear conditions using the ENF (End-Notched Flexure) method and interlayer strength. The test results of samples of polymer composite materials with a carbon reinforcing filler with different surface densities are presented. The experimental data were used to identify the parameters of the VCCT (Virtual Crack Closure Technique) and CZM (Cohesive Zone Model) closure models used to describe the development of cracks in the composites under consideration. It was found that the parameters determining the strength of layered composites are such characteristics as interlayer strength and crack resistance. It was found that the decrease in the strength of individual layers of the composite does not always affect the current stress state of the entire structure, which is often difficult to detect experimentally, but can significantly affect the further behavior of the object under study provided that the crack develops further.

## АННОТАЦИЯ

Волокнистые композиты на основе полимерных матриц являются перспективными конструкционными материалами, отвечающими высоким требованиям к прочности, надежности, долговечности, твердости. Поэтому композиционные материалы нашли широкое применение в качестве конструкционных материалов для изделий аэрокосмической отрасли. Проблемы, связанные с разрушением волокнистых композитов, были актуальны на всех этапах развития технологии. Разнообразие армирующих волокон и полимерных связующих, а также схемы армирования позволяют направленно контролировать прочность, жесткость, уровень рабочих температур и другие свойства полимерных композиционных материалов. В данной статье рассмотрена методика экспериментального определения механических свойств волокнистых полимерных композиционных материалов на основе углеродных волокон, включающая определение межслоевой вязкости разрушения при нагружении в условиях отрыва по методу двухконсольной балки (DCB – Double Cantilever Beam), вязкости разрушения в условиях поперечного сдвига по методу ENF (End-Notched Flexure) и межслоевой прочности. Приведены результаты испытаний образцов полимерных композиционных материалов с углеродным армирующим наполнителем с различной поверхностной плотностью. Результаты экспериментальных данных использованы для идентификации параметров моделей закрытия виртуальной трещины VCCT (Virtual Crack Closure Technique) и когезионной зоны CZM (Cohesive Zone Model), использованных для описания развития трещин в рассматриваемых композитах. Установлено, что определяющими прочностью слоистых композитов параметрами являются такие характеристики как межслоевая прочность и трещиностойкость. Было установлено, что снижение прочности отдельных слоев композита не всегда влияет на текущее напряженное состояние всей конструкции, что зачастую трудно обнаружить экспериментально, но может существенно повлиять на дальнейшее поведение исследуемого объекта при условии дальнейшего развития трещины.

**Ключевые слова:** *углеродное волокно, параметры трещиностойкости, вязкость разрушения, межслойная прочность, полимер.*

## 1. INTRODUCTION

To create modern aerospace technology, materials with high strength, hardness, heat resistance, corrosion resistance, other characteristics and combinations of these properties are required. Fibre composites based on polymer matrices are promising structural materials since they have good specific characteristics of strength and stiffness. These materials are nowadays increasingly being used as part of aviation, space, transport, and other structures (Babaytsev and Zotov, 2019). This is

due to the requirements for weight efficiency of products, to satisfy which it is necessary to use materials with high levels of specific properties (Naghypour *et al.*, 2011; Krayushkina *et al.*, 2016; Landry and La Plante, 2012). The use of composite materials in the aviation industry significantly reduces the material consumption of structures, increases the material utilisation rate up to 90%, reduces the number of equipment, and dramatically reduces the complexity of manufacturing structures by several times reducing the quantity of parts included in them.

Nonetheless, there are many problems

specific to layered composite materials, which limit their scope (Babaytsev and Zotov, 2019). One of the main issues that arise in the design of structures made of polymer composite materials is ensuring strength under the conditions of prolonged stress and in the conditions of damage development. Notably, essential and determining strength parameters are such characteristics as interlayer strength and fracture toughness (Belnoue *et al.*, 2016; Orlov *et al.*, 2003; Nelson and O'Toole, 2019; Kyanishbayev *et al.*, 2016; Zhang *et al.*, 2019; Krayushkina *et al.*, 2019). For a more accurate assessment of strength and resource characteristics of the material, sophisticated tests are required, including tests targeted at determining the parameters of crack resistance.

To evaluate the stress-strain state of multilayered structures, we can use the final parameter of fracture mechanics can be used – the intensity of energy release –  $G$ . To find this value, the Virtual Crack Closure Technique (VCCT) method is frequently used (Liu and Islam, 2013; Krueger, 2013; Senthil *et al.*, 2013). At the same time, the use of interface elements based on CZM (Cohesive Zone Model) model (Chandra *et al.*, 2002; Skvortsov *et al.*, 2014; Cornec *et al.*, 2003; De Borst, 2003; Yang and Cox, 2005; Xie and Waas, 2006; Harper and Hallet, 2010) makes it possible to study the nucleation and development of stratification without specifying the initial defect and rearrangement of finite element mesh during its propagation. The inclusion of temperature effects was considered in (Formalev *et al.*, 2018; Bulychev and Kuznetsova, 2019; Makarenko and Kuznetsova, 2019; Hnatiuk *et al.*, 2019; Formalev and Kolesnik, 2019; Formalev *et al.*, 2019).

Therefore, resistance to interlayer fracture is a necessary condition for ensuring the solidity and operability of layered composite materials during the operation. Moreover, theoretical and experimental study of crack resistance parameters is an urgent problem of modern composite materials mechanics.

## 2. MATERIALS AND METHODS

The authors examined carbon-polymer composite materials with different surface densities for laying reinforcing filler: 400 g/m<sup>2</sup>, 600 g/m<sup>2</sup>, 800 g/m<sup>2</sup>. Reinforcing filler brand Torey T800, matrix - Poly (bisphenol-A-co-epichlorohydrin) Liquid Epoxy resin (Biphend A type) The characteristics of the materials are presented in Table 1.

To study the interlayer strength, tests were performed on three-point bending samples. Tests were done according to ASTM D2344. The study of interlayer fracture toughness (fracture toughness) under loading for tear conditions under the DCB method was studied according to ASTM D 5528 on rectangular samples with preliminary delamination in the middle plane at one end (ASTM D5528, 2013). This artificial defect initiated further stratification (Chung and Blaser, 1980; Kwatra *et al.*, 2009). White paint and a scale were applied to the side face of each sample, which is required to identify the crack. The load on the sample was transmitted through hinges. Three batches of samples were tested, 10-15 pieces each. Samples were 125 mm long, 25.1 mm wide, and 3.3 – 4.5 mm thick (depending on the batch) (Figure 1).

The fracture toughness under shear conditions was determined pursuant to the ENF method according to ASTM D 7075, as in the experiments described above, on rectangular samples, at one end of which a non-adhesive insert was inserted in the middle plane during production. Three batches were tested, each containing 10 to 15 samples. The simulation of experiments on ASTM D 5528 (ASTM D5528, 2013) and ASTM D 7905 (ASTM D7905, 2013) was done using software packages Simulia ABAQUS and Ansys. The methods used were the VCCT (Virtual Crack Closure Technique) and CZM (Cohesive Zone Model). The samples were modelled as deformable three-dimensional bodies consisting of two parts of equal thickness.

The virtual crack technique (VCCT) uses the principles of linear mechanics of elastic fracture and, therefore, is suitable for tasks in which brittle crack propagation occurs along predetermined surfaces. The VCCT technique is based on the assumption that the strain energy released when a crack increases by a certain amount is the same as the energy needed to close a crack by the same value. A “surface-to-surface” contact was fixed between the two halves. The bundle formation zone was modeled using the VCCT element. To simulate tests according to ASTM D 7905, the procedure described above was also applied, except the boundary conditions (ASTM D7905, 2013). Here the sample was tested for three-point bending.

Tests on the separation and simulations using the CZM models. The Cohesive Zone Model (CZM) is based on the assumption that the ability to transfer stress between two separated faces when they are separated from each other is not

entirely lost, but instead becomes a progressive event, determined by a gradual deterioration in the rigidity of the interlayer surface. A strong point of the CZM method: a model using the CZM predicts the beginning and describes the delamination process without having to accept the assumption that there is a small supposed crack. Weak points: the need for data that can only be obtained from a complex set of experiments, as well as high sensitivity to input parameters, required fine mesh. The simulation of the experiment was carried out in a flat setting. The sample was modelled, consisting of two parts of identical thickness.

### 3. RESULTS AND DISCUSSION:

According to tests, it was established that the interlayer strength of the samples was 37 MPa (400 g/m<sup>2</sup>), 35 MPa (600 g/m<sup>2</sup>), 57 MPa (800 g/m<sup>2</sup>) with a variation of experimental values not more than 10%. The test results of ASTM D 5528 for determining the fracture toughness under shear conditions are shown in Figure 2 and Table 2 (ASTM D5528, 2013). Test results of ASTM D 7905 to determine fracture toughness in terms of the separation are presented in Figure 2b and Tables 3, and 4 (ASTM D7905, 2013). The calculation, according to ASTM, was done by several methods: Modified Beam Theory (MBT) Method, Compliance Calibration (CC) Method, Modified Compliance Calibration (MCC) Method.

Simulation of experiments implemented according to the methods of VCCT and CZM provides a good comparison with the experiment, but only from the beginning of the growth of the separation. It was not possible to predict further stratification growth using the applied techniques. For example, a result of the calculation by the model CZM rendered the following dependency (Figure 3).

The model of the cohesive zone is susceptible to input parameters. For solution within the framework of this model, it is essential to know the crack resistance parameters, which can only be learned from the experiment on individual samples by specific methods. This model also requires a fine mesh and thorough adjustment of the solver.

### 4. CONCLUSIONS:

As part of the research, an experimental and theoretical study of mechanical properties of composite materials reinforced with carbon filler

was carried out. A feature of the deformation of spatial structures made of composite materials is the possibility of the occurrence of not only cracks due to rupture of fibres and matrix material, but also the formation of delamination zones during deformation. As a result, a technique was developed for doing CRFP tests aimed at studying the interlayer strength, determining the specific work of stratification in conditions of the GIC separation using the DCB method, and under transverse shear conditions GIIC using the ENF method. An experimental base was developed; practical recommendations were arranged for further research. Samples of carbon fibre with different densities of reinforcing filler were tested.

As a result of experimental tests, it was found that the interlayer strength of the samples is 37 MPa (400 g/m<sup>2</sup>), 35 MPa (600 g/m<sup>2</sup>), 57 MPa (800 g/m<sup>2</sup>) with a variation of experimental values of not more than 10%. The experimental data were compared with models of processes of appearance and development of cracks in the finite element complexes ABAQUS and Ansys based on VCCT models, cohesive elements. Using the VCCT model, it was possible to obtain only the critical load of the start of the first crack, further stratification using this model could not be modelled, the results obtained did not correlate with experimental data at all.

The cohesion area model is susceptible to input parameters. To solve within the framework of this model, it is necessary to know the crack resistance parameters, which can only be learned from experiments on individual samples by specific methods. This model also requires a fine mesh and thorough adjustment of the solver. Within the framework of this model, it was possible to track the appearance of the first crack, and also to trace further development of the crack within the first three growth stages with an acceptable error.

### RESUMO

Uma das tecnologias inovadoras importantes é a criação de estruturas de grande porte que funcionam por um longo período no espaço e atendem a restrições rigorosas das características gerais de massa. Entre essas estruturas, em primeiro lugar, está a seção de treliças de suporte de carga. Este artigo apresenta os resultados de estudos experimentais de compressão das seções de treliças de suporte de carga na estrutura de grade. Recentemente, os invólucros cilíndricos de grade compostos são usados como carcaças de naves espaciais. O invólucro de grade é uma estrutura de suporte à qual os instrumentos e mecanismos da espaçonave estão conectados. A seção de treliça de suporte é feita do material compósito de polímero da estrutura de grade usando fibras de carbono. O objetivo dos testes é confirmar a possibilidade de criar uma estrutura de grade leve usando um material compósito de polímero reforçado com fibra de carbono. Para atingir esse objetivo, os autores definiram as seguintes tarefas: escolher o preenchimento de carbono de materiais compósitos de polímeros (MCP); escolher os ligantes de MCP, determinar o grau de reforço de fibra de carbono; escolher o número e trajetórias de orientação das nervuras em espiral, o número de nervuras anulares e o tamanho das nervuras individuais. Para teste, foi desenvolvida a "Instalação para teste da treliça de suporte". Como resultado da pesquisa, são obtidos os indicadores calculados para garantir a capacidade de carga e a rigidez sob a aplicação de carga compressiva axial. Simultaneamente com a determinação da capacidade de carga, as características de deformação da estrutura são determinadas duas vezes para confirmar sua repetibilidade, bem como a natureza linear da dependência de deformações axiais e radiais como resultado da carga aplicada.

### ABSTRACT

One of the significant innovative technologies is the creation of large-sized structures that work for a long time in space and meet stringent restrictions on overall mass characteristics. Among these structures, in the first place, is the section of bearing truss (BT). This article presents the results of experimental studies of sectors of load-bearing trusses of mesh design for compression. Recently, composite mesh cylindrical shells are used as spacecraft housings. The mesh shell is a supporting structure to which the instruments and mechanisms of the spacecraft are attached. The truss section is made of cross-linked polymer composite material with carbon fibers. The objective of the tests is to confirm the possibility of creating a lightweight mesh construction using a carbon fiber reinforced polymer composite material. To achieve this goal, the authors were assigned the following tasks: selection of carbon filler of polymer composite materials (PCM); selection of PCM binder; determination of the

degree of carbon fiber reinforcement; choice of the number and orientation paths of spiral ribs, number of ring ribs and the sizes of individual ribs. As a result of the research, the calculated indicators for ensuring the bearing capacity and stiffness under the application of axial compressive load were obtained. At the same time, with the determination of bearing capacity, the deformation characteristics of the structure were twice determined in order to confirm their repeatability, as well as linear nature of the dependence of axial and radial deformations as a result of the applied load.

## АННОТАЦИЯ

Одной из важных инновационных технологий является создание крупногабаритных конструкций, длительное время работающих в условиях космического пространства и отвечающих жестким ограничениям по габаритно-массовым характеристикам. К числу таких конструкций, в первую очередь, относится секция несущих ферм (НФ). В данной статье приведены результаты экспериментальных исследований секций несущих ферм сетчатой конструкции на сжатие. В последнее время композитные сетчатые цилиндрические оболочки находят применение в качестве корпусов космических аппаратов. Сетчатая оболочка является несущей конструкцией, к которой присоединяются приборы и механизмы космического аппарата. Секция несущей фермы изготовлена из полимерного композиционного материала сетчатой конструкции с использованием углеродных волокон. Целью испытаний является подтверждение возможности создания облегченной сетчатой конструкции с использованием полимерного композиционного материала, армированного углеродным волокном. Для достижения поставленной цели перед авторами были поставлены такие задачи: выбор углеродного наполнителя полимерных композиционных материалов (ПКМ); выбор связующего ПКМ, определение степени армирования углепластика; выбор количества и траекторий ориентации спиральных ребер, количества кольцевых ребер и размеров индивидуальных ребер. Для проведения испытаний была разработана «Установка для испытаний несущей фермы». В результате исследований получены расчетные показатели по обеспечению несущей способности и жесткости в условиях приложения осевой сжимающей нагрузки. Одновременно с определением несущей способности дважды определяются деформационные характеристики конструкции с целью подтверждения их повторяемости, а также линейного характера зависимости осевых и радиальных деформаций в результате действия приложенной нагрузки.

**Ключевые слова:** *тетрамотка, углеродное волокно, несущая ферма, космический аппарат, ракетный носитель.*

## 1. INTRODUCTION:

One of the essential innovative technologies is the creation of large-sized structures that work for a long time in space and meet stringent restrictions on overall mass characteristics. Among these structures, in the first place, is the section of bearing truss (BT). For the production of a section truss of structural carbon fiber, the technology of tetra-winding can be effectively used, which allows one to obtain cylindrical compartments that withstand intense compressive loads. This design has high bending stiffness and compressive strength in combination with reduced weight (Berezovskii *et al.*, 2015; Babaytsev *et al.*, 2017a; Varsavas and Kaynak, 2018).

To increase rigidity, BT design provides reinforcing axial stringers (longitudinal ribs) in four planes along four ribs, as well as ending flanges made in a single technological winding cycle together with mesh shell. These problems

were considered in detail in (Antufev *et al.*, 2019a; Antufev *et al.*, 2019d; Antufev *et al.*, 2019c; Bodryshev *et al.*, 2019; Zhavoronok *et al.*, 2019; Rabinskiy and Tushavina, 2019; Dmitriev *et al.*, 2011).

The section of bearing truss (BT) is one of the structures that have been operating for a long time in outer space conditions and meet stringent restrictions on overall mass characteristics. Power elements of the design of spacecraft stages, interstage compartments, propulsion systems, space tug support frames, spacecraft, and space platforms are traditionally made in the form of frame-tubular shells from various alloys (aluminum, titanium), as well as stainless steel (Babaytsev *et al.*, 2017a; Babaytsev *et al.*, 2017b; Antufev *et al.*, 2019a; Antufev *et al.*, 2019b; Babaytsev and Zotov, 2019; Sevryukova *et al.*, 2012). In recent years, both in foreign and domestic practice, non-metallic composite materials reinforced with glass, organic, or carbon fibers have become increasingly used to reduce

the mass characteristics of structures for space constructions (Berezovskii *et al.*, 2015; Kyanishbayev *et al.*, 2016; Suprun *et al.*, 2018; Babaytsev *et al.*, 2017a; Babaytsev *et al.*, 2017b; Koshoridze *et al.*, 2017; Babaytsev and Zotov, 2019; Babaytsev *et al.*, 2019). Some examples are the following:

- mesh shells of transition compartments made of organoplastic having unidirectional reinforcement with the technology of continuous winding of the thread on forming tooling;

- conical adapters and cylindrical power truss of spacecraft and space platforms in the form of wire-mesh shells made of carbon fiber reinforced with high-strength carbon fiber.

As practice demonstrates, the use of composites provides a more than twofold decrease in the characteristics of the load-bearing elements of power frames and trusses in comparison with metal structures with the same levels of bearing capacity, rigidity, and stability of shells. Production capabilities make it possible to create large enough products with a diameter of more than 2 meters and a length of more than 6 meters with the appropriate refinement of the process and technological equipment (Golushko and Semisalov, 2015; Pintossi *et al.*, 2019).

## 2. MATERIALS AND METHODS:

As applied to the section of bearing truss (BT) of spacecraft, the smallest weight characteristics can be realized using PCM reinforced with both aramid and carbon fibers, however, taking into account rather high levels of radiation exposure, requirements for a long-term stay of the product in open space and higher stiffness characteristics, preference ought to be given to carbon fiber structures (Umbetov *et al.*, 2016; Mustafin, 2006).

Polymer composite materials are understood as multicomponent materials consisting of a plastic base (matrix), which is reinforced with fillers that have high strength and rigidity. The properties of the new material quantitatively and qualitatively differ from the properties of each of its components. By changing the composition of the matrix and the filler, their ratio, the orientation of the filler, a wide range of materials with the desired set of properties is obtained. The use of polymer composite materials can reduce the mass of the structure while maintaining or improving its mechanical features.

The use of PCMs based on glass, polymer,

carbon, and ceramic fibers is currently directly related to progress in rocket science, aviation, automotive, shipbuilding, mechanical engineering, construction (Tokiwa *et al.*, 2009; Farhadinia, 2014). The properties of PCMs depend on the choice of the initial components and their ratio, the interaction between them, the method and technological conditions for manufacturing the product (pressure, temperature, time), additional processing of the product, and a number of other factors. The determining factor in creating a PCM is the interaction and mutual influence of components at the fiber-matrix interface (binder). The higher the required properties of the PCM created for structural use, the more complex the set of requirements must be maintained when choosing the source components (Gattringer *et al.*, 2019; Mishra *et al.*, 2019; Hao *et al.*, 2019). The final characteristics of carbon-epoxy composites are strongly influenced by the chemical structure of the epoxy resin, its properties, and curing conditions. Improving the adhesive characteristics is achieved by creating a covalent chemical bond at the interface as a result of surface treatment of the fibers and modification of the composition of the binder (Alosime, 2019; Kumar, 2019). The mesh structure consists of two symmetrical systems of spiral ribs and a system of ring ribs. Spiral ribs are located at angles to the generatrix of the cylinder. The annular ribs pass through the midpoints of the segments of the spiral ribs located between the points of their intersection.

In this case, the most relevant development objectives are:

- selection of carbon filler of PCM (fiber) that meets the optimal set of requirements for physic-mechanical characteristics and provides the possibility of its application in continuous winding technologies (except for breaks at a tension of the thread and kinks both in the manufacture of elements of large curvature and in the movement of thread (wisp) in the layout and saturation systems of the binder;

- selection of PCM binder that provides uniform impregnation of carbon tow and sufficient adhesion to the formed unidirectional matrix;

- determination of the degree of carbon fiber reinforcement, which is responsible for compressive strength of unidirectional PCM (in the direction of calculations and carbon tow) at least 0.5 GPa and tensile strength at least 0.9 GPa;

- to optimize the rigidity and strength of PCM while minimizing the mass of the mesh shell – choice of the number and orientation paths of

spiral ribs, number of ring ribs and the sizes of individual ribs (width, height – for the implementation of automated manufacturing in a single technological cycle – it is advisable to keep the ribs dimensions constant over the entire mesh surface).

To test the BT at this stage of the study, the axial compressive force was adopted as the main load acting on the shell: the calculated value of which corresponds to the bearing capacity of 14 tf. Total dimensions of the BT section are – diameter 1200 mm, length 3800 mm. To increase rigidity, the design provides reinforcing axial stringers (longitudinal ribs) in four planes of four ribs, as well as end flanges (Skvortsov *et al.*, 2012; Tkachev *et al.*, 2018; Baymuratov *et al.*, 2018).

The mesh elements have the following geometric dimensions:

- rib height – 15 mm,
- the thickness of the spiral ribs is 3 mm,
- the thickness of the annular ribs – 3 mm,
- the thickness of the longitudinal ribs – 4.2 mm
- the angle of orientation of the spiral ribs relative to the generatrix – 29 degrees.

BT has two end frames. The frames intersecting the ribs of the mesh structure are made of carbon fiber. Based on the accepted structural parameters and geometric dimensions, the design of the BT section was done. A general view of BT is presented in Figure 1.

To test the design of BT for mechanical strength (axial compression), "Installation for testing the load-bearing truss" was developed and manufactured. The test bench layout is displayed in Figure 2. The structure of the stand includes base floor plate 1; lower mounting plate with a restrictive ring to prevent radial displacement of the model from the axis and its alignment 2; the upper base and mounting plate with a restrictive ring to prevent radial displacement of the model from the axis and its alignment 3; power exciter (manual hydraulic jack) 4; force meter (strain gauge force sensor) 5; set of centering sleeves 6; technological support for mounting 7; string type displacement sensors, potentiometric – 8 (four vertical through 900 (Dat1-Dat4) and one horizontal in diameter (Dat5). Sensors Dat1 and Dat2 are nearby, as are Dat3, Dat 4.

The model was loaded according to the step diagram with a step of ~ 20 kN and exposure at each step of ~ 100 seconds to the total compressive force of ~ 138 kN (14 tf). Continuously recorded magnitude of the

deformation of BT in the axial and radial directions and accompanied by visual monitoring of the state of the structure. At the maximum value of the applied compressive force with a hold time of 10 minutes.

### 3. RESULTS AND DISCUSSION:

Two tests of the BT section with the identical loading mode were carried out. The second test was carried out in order to confirm the absence of the phenomenon of micro-tears and cracks caused by the cyclic regime of load changes. The reduction in length and increase in diameter in cross-section in the middle of the height of the truss model is shown in Figure 2 and Tables 1, 2.

The design of the transition compartment constitutes the core system that remains unchanged after exposure to loads. The farm is manufactured by continuously winding a tow with a binder based on phenolic resins. Production of transition compartments started involving carbon composite materials to reduce mass characteristics while maintaining the strength and rigidity of the structures. The use of such materials provides a more than twofold decrease in mass characteristics compared to metal structures while maintaining the rigidity and strength of structural elements.

Figure 3 and Figure 4 present the first readings of recording devices during a time period. The stepwise nature of loading can be seen. During the initial period of time, a linear increase in readings of the string displacement sensors is observed at practically constant load. This mode corresponds to the movement of the plate 7 up to its contact with the counter plane of the end flange and the formation of the snug fit of both plates of the stand to the corresponding flanges of the model. At some point in time, the force sensor begins to register an increase in corresponding value, and at the same time, the nature of the sensor's readings changes to a gentler one. Based on the tests, was obtained a dependency on indications of sensors (external load) on time. (Figure 3). Figure 4 presents a compression diagram (the dependence of truss movements and an increase in diameter depending on the applied forces).

### 4. CONCLUSIONS:

1. Through the measurement range, the model of the BT section retained its integrity and stability, and there were no violations of continuity

of the polymer composite material, cracks, or delamination.

2. The nature of the deformation of the BT prototype when applying axial force is close to linear, which indicates the absence of irreversible fracture processes in the polymer composite material and development of only elastic stresses without accumulation of damage. The elastic nature of displacements is also confirmed by the similarity of displacement curves in the load-unloading modes of the model (there are no residual deformations within the measurement accuracy).

3. The relative value of axial strain was ~ 0.1%. There was good convergence of the measurement results with the strength calculation data, and the errors did not exceed 6%.

4. The registered small levels of structural displacements under the action of compressive load and their satisfactory reproducibility, including at significant forces of 14 tf, lets us consider the possibility of modernizing the design scheme of the model of BT section to provide an additional reduction in its mass.

Particularly, it is advisable to optimize the size and number of axial ribs (stringers). Likewise, in further work, it is advisable to clarify the possible variation in properties of the polymer composite material implemented in the design of the model using the suggested manufacturing technology.

BT tests have demonstrated that at a given axial load of 14 tf, the product retains its bearing capacity and stability at the levels of relative deformations of no more than 0.1%, which corresponds to the results of strength calculations for given properties of the material. Deformations of the product are noticed in the elastic region without significant changes. The deformation characteristics of the model remain stable and vary linearly depending on the applied load.

## 5. ACKNOWLEDGMENTS:

The work was carried out with the financial support of the state project of the Ministry of Education and Science project code "Modern technologies of experimental and digital modeling and optimization of spacecraft systems parameters", project code FSFF-2020-0016.

**RESUMO**

As doenças alérgicas são um dos problemas mais prementes da medicina prática. Segundo estatísticas da Organização Mundial da Saúde, cerca de 40% da população mundial sofre de alergias. Atualmente, o diagnóstico de alergia molecular (AM) é o método mais útil para selecionar os pacientes para prescrever imunoterapia com o objetivo de tratar alergias (imunoterapia com alérgenos), determinar a reatividade cruzada e a gravidade da reação associada a vários alérgenos. O diagnóstico de alergia molecular tem vantagens no diagnóstico de pacientes com sintomas alérgicos – asma, febre do feno, eczema, urticária, sintomas gastrointestinais, síndrome alérgica oral ou anafilaxia. Baseia-se na escolha pelo médico de alérgenos individuais ou no uso de microchips e oferece uma grande quantidade de informações relacionadas ao perfil de IgE de pacientes sensíveis a alérgenos. O método mais eficaz de tratamento de doenças alérgicas é a imunoterapia com alérgenos, que afeta todas as partes patogênicas do processo alérgico e tem um longo efeito preventivo após a conclusão dos cursos de tratamento. O objetivo do artigo é estudar a prevalência de reatividade de IgE a importantes alérgenos recombinantes no contexto de tipos de imunoterapia com alérgenos. Durante o trabalho, os pacientes foram examinados pelo método de diagnóstico molecular alérgico. O artigo apresenta os resultados do estudo comparativo da presença de IgE específica no soro de pacientes com sensibilidade confirmada aos principais alérgenos recombinantes: absinto Art vI, Art v3, Phleum Phl p1, Phl p5 e bétula Bet v1 por um período de três anos. Os dados obtidos confirmam a alta eficácia da imunoterapia com alérgenos e seu efeito positivo na diminuição da sensibilidade em pacientes com febre do feno em comparação com os resultados do grupo de imunoterapia parenteral.

**Palavras-chave:** febre do feno, diagnóstico de alergia molecular, principais alérgenos recombinantes, imunoterapia com alérgenos.

**ABSTRACT**

Allergic diseases are one of the most urgent problems of practical medicine. According to statistics of the World Health Organization, about 40% of the world's population suffers from allergies. Molecular allergy diagnostics (MA) is currently the most useful patient selection method for prescribing allergen-specific immunotherapy (ASIT), determining cross-reactivity, and the severity of the reaction associated with various allergens. Molecular allergic diagnosis has advantages for the diagnosis of patients with allergic symptoms – asthma, pollinosis, eczema, hives, gastrointestinal symptoms, oral allergic syndrome, or anaphylaxis. It is based on the choice of individual allergens by a doctor or the use of microarrays and offers a large amount of information related to the IgE profile of sensitized patients. The most effective method of treatment for allergic diseases is allergen-specific immunotherapy, which affects all pathogenetic links of the allergic process and has a long-term preventive effect after the completion of treatment courses. The aim of the article is to study the prevalence of IgE

reactivity to major recombinant allergens on the background of the types of allergen-specific immunotherapy. In the course of the work, patients were examined by allergic molecular diagnostics. The article shows the results of a comparative study of the presence of specific IgE in the serum of patients with confirmed sensitization to major recombinant allergens: wormwood Art vI, Art v3, timothy Phl p1, Phl p5 and birch Bet v1 for a three-year period. The data obtained confirm the high efficiency of sublingual immunotherapy (SLIT) and its positive effect on the reduction of sensitization in patients with pollinosis compared with the results of the parenteral immunotherapy group (sublingual immunotherapy).

## АННОТАЦИЯ

Аллергические заболевания на сегодняшний день являются одной из наиболее актуальных проблем практической медицины. Согласно статистическим данным Всемирной организации здравоохранения, аллергией страдают около 40% населения нашей планеты. На сегодняшний день молекулярная аллергодиагностика (МА) является наиболее полезным методом отбора пациентов для назначения аллерген-специфической иммунотерапии (АСИТ), определения перекрестной реактивности и тяжести реакции, ассоциированной с различными аллергенами. Полисенситизированные пациенты с неясными симптомами, типом сенситизации, или у кого нет ответа на лечение, могут быть диагностированы в стандартной лаборатории при доступности в ней МА. Молекулярная аллергодиагностика обладает преимуществами для диагностики пациентов с аллергическими симптомами – астмой, поллинозом, экземой, крапивницей, желудочно-кишечными симптомами, оральным аллергическим синдромом или анафилаксией. Определение истинной сенситизации так же важно, как и выявление вторичной сенситизации под действием перекрестно реагирующих аллергенов. Молекулярная аллергодиагностика, основанная на выборе врачом отдельных аллергенов или использовании микроматриц, предлагает большой объем информации, относящейся к IgE-профилю сенситизированных пациентов. Наиболее эффективным методом лечения при аллергических заболеваниях является аллерген-специфическая иммунотерапия, воздействующая на все патогенетические звенья аллергического процесса и обладающая длительным профилактическим эффектом после завершения лечебных курсов. Целью исследования явилось изучение наличия специфических IgE в сыворотке крови пациентов с подтвержденной сенситизацией к рекомбинантным мажорным аллергенам на фоне аллерген-специфической иммунотерапии. В статье изображены результаты сравнительного изучения наличия специфических IgE в сыворотке крови пациентов с подтвержденной сенситизацией к рекомбинантным мажорным аллергенам: полыни Art vI, Art v3, тимopheевки Phl p1, Phl p5 и березы Bet v1 в течение трехлетнего периода. Полученные данные подтверждают высокую эффективность сублингвальной аллерген-специфической иммунотерапии (СЛИТ) и ее положительное влияние на снижение сенситизации у больных поллинозом в сравнении с результатами группы парентеральной аллерген-специфической иммунотерапии (ПИТ).

**Ключевые слова:** *поллиноз, молекулярная аллергодиагностика, рекомбинантные мажорные аллергены, аллерген-специфическая иммунотерапия.*

## 1. INTRODUCTION

Allergic diseases are one of the most urgent problems of practical medicine. This is due to the high prevalence and the continuous increase in the number of diseases, as well as the increase in severe clinical manifestations, which often cause a deterioration in the quality of life and disability of patients (Canonica *et al.*, 2013a; Perkin and Genuneit, 2017; Brozek and Cuello-Garcia, 2016; Namazova-Baranova, 2011; Morenko, 2010). According to statistics of the World Health Organization, about 40% of the world's population suffers from allergies. The first place are respiratory allergies, about 12-45% of them, specifically pollinosis (Ilyina and Pavlova,

2016; Bousquet *et al.*, 2016; FitzGerald *et al.*, 2014; Papadopoulos *et al.*, 2012).

A feature of allergic diseases in the Republic of Kazakhstan is that the main allergenic plants are wormwood and other weeds, the intensity of sensitization is about one million times greater than that observed in Central Europe and the European part of the Russian Federation (Kurbacheva *et al.*, 2013; Maslova, 2012; Calderon *et al.*, 2011; Gorbash *et al.*, 2015; Zhumambayeva *et al.*, 2014). The main reason of the increase in the incidence of pollen and the prevalence of its medium and heavy forms is the leadership of symptomatic pharmacotherapy over pathogenetic allergen-specific immunotherapy

(ASIT) The most effective method of treatment for allergic diseases is allergen-specific immunotherapy, which affects all pathogenetic links of the allergic process and has a long-term preventive effect after the completion of treatment courses (Saltabaeva and Morenko, 2015; Durham, 2006; Canonica *et al.*, 2014; Zhuravleva *et al.*, 2019; Valovirta, and Berstad, 2011). If parenteral methods developed in 1911 have already received general acceptance worldwide, then oral methods for decades have been discredited by using untreated vaccines. Such vaccines have not been depolymerized and depigmented (Calderon *et al.*, 2012; Abdrakhmanova *et al.*, 2019).

Only in the last two decades, these methods began to be widely used first in European countries, later in North and Central America, and in the last years methods are already used in Kazakhstan. A comparative study of the efficacy of oral and parenteral allergen-specific immunotherapy (ASIT) has not been adequately studied, mainly in European countries (Cheryl *et al.*, 2013, Douladiris, 2013; Kudabayeva *et al.*, 2014; Kudabayeva *et al.*, 2017; Valenta *et al.*, 2014). In our republic, similar results of the study were not previously published. The region of Northern Kazakhstan, where the capital Nur-Sultan is located, is characterized by heterogeneous climatic conditions due to the long extent, heterogeneous surface structure, and characteristic landscapes. The specificity of pollination in Nur-Sultan is special in relation to a relatively short summer, where there are shifts in time of flowering of trees, weeds, and meadow grasses, which complicates the establishment of true sensitization to certain allergens. Nur-Sultan is located in a spacious steppe and is exposed to a wind rose, with a strong pollen direction from the southern regions and the influence of several different pollen sources of allergens at the same time, which lead to cross-allergy (The climate of Astana, 2019). To determine the true sensitization in cross-reactions in polysensitized patients when traditional diagnostic tests and case history data are insufficient to determine significant allergens for the correct selection of therapy, prognosis, and effectiveness, molecular allergy diagnostics with recombinant allergens is used (Becker *et al.*, 2016; Canonica *et al.*, 2013b; Ramilyeva *et al.*, 2019; Burkitbaiev *et al.*, 2017; Fooke-Achterrath *et al.*, 2012; Spergel, 2010; Valenta *et al.*, 2011).

The aim of the article is to study the prevalence of IgE reactivity to major recombinant allergens on the background of the types of allergen-specific immunotherapy.

## 2. MATERIALS AND METHODS

Molecular allergy diagnostics (MA) is currently the most useful patient selection method for prescribing allergen-specific immunotherapy (ASIT), determining cross-reactivity, and the severity of the reaction associated with various allergens. Polysensitized patients with unclear symptoms, type of sensitization, or who have no response to treatment can be diagnosed in a standard laboratory with the availability of MA in it. Molecular allergic diagnosis has advantages for the diagnosis of patients with allergic symptoms – asthma, pollinosis, eczema, hives, gastrointestinal symptoms, oral allergic syndrome, or anaphylaxis. Determining true sensitization is just as important as identifying secondary sensitization by cross-reacting allergens. Molecular allergy diagnosis, based on the choice of individual allergens by a doctor or the use of microarrays, offers a large amount of information related to the IgE profile of sensitized patients (Valenta *et al.*, 1991; Smiyan *et al.*, 2015; Cromwell *et al.*, 2011; Jutel *et al.*, 2005; Saltabaeva and Morenko, 2017).

The study focuses on the presence of specific IgE in the serum of patients with confirmed sensitization (by Molecular allergy diagnostics) to pollen from wormwood to recombinant major recombinant allergens: wormwood Art vI, Art v3, timothy Phl p1, Phl p5 and birch Bet v1 for a three-year period (Tables 1, 2, and 3). Surveys were carried out in the medical and health center “Umit” (Nur-Sultan, Republic of Kazakhstan). The study involved 228 patients with varying degrees of severity of hay fever, among whom were children from 5 to 18 years old and an adult population (113 patients were males, 115 were females). The average age was  $23.5 \pm 0.9$  years, and the minimum age was 5 five years, t, the maximum was 60 years. The studied respondents were randomized into two groups: group 1 included 126 (55.3%) patients who took sublingual immunotherapy (SLIT) (Durham, 2006), group 2 included 102 (44.7%) patients who received parenteral immunotherapy (PIT) (Kurbacheva *et al.*, 2013).

In the course of the work, 153 (67.1%) patients from the 1st group (SLIT) 95 (75.4%), from the 2nd group (PIT) 58 (56.9%) patients with pollinosis were examined by allergic molecular diagnostics and having positive skin scratch tests for native allergens with polysensitivity to mixes of weeds, meadow grasses, and trees (Douladiris, 2013).

Non-parametric methods of research,

Wilcoxon criterion, Mann-Whitney criterion, Friedman criterion, mean value, standard deviation, median, 25th, and 75th percentile were used to evaluate the parameters (Saltabayeva *et al.*, 2016a; Saltabayeva *et al.*, 2016b).

### 3. RESULTS AND DISCUSSION:

The enzyme immunosorbent assay using major recombinant allergens Art vI, Art v3, Phl p1, Phl p5, and Bet v1 was diagnosed with sensitization to these allergens as follows: Art v 1 – in 26 (17.0%), Art v3 – in 9 (5.9%), Art v1-Art v3 – in 73 (47.7%), Art v1.3-Bet v1 – in 20 (13.1%), Art v1.3-Phl p1.5 – in 16 (10.5%), Art v1,3-Bet v1-Phl p1.5 – in 9 (5.9%) (Figure 1).

Among inhaled pollen allergens, the highest degree of sensitization was determined to Art v1-Art v3. After a course of specific immunotherapy, the total number of patients with significant sIgE decreased 1.4 times. The results obtained correlate with known scientific data. In a number of works (Kulis, 2011; Radauer *et al.*, 2010) a high level of sensitization to recombinant wormwood allergens is noted in various populations of the European part of Russia, Kyrgyzstan, including wormwood, which coincides with our data and confirms the presence of a large number of IgE epitopes in Art v1-Art v3 to weed pollen allergens.

At the same time, antibodies to the main allergen of the monopole Art v1-Art v3 are found in 73 (47.7%) patients with seasonal allergic rhinitis. The identification of high levels of Art V1-Art v3 major antibodies in patients was important for developing criteria for the selection of therapy and evaluating the effectiveness of ASIT. Most scientific sources confirm this data, which describes nine different allergens isolated from wormwood pollen (*Artemisia vulgaris*), including two major allergens (Art vI and Art v3), which are often responsible for cross-allergy (Eigenmann, 1998). The complete structure of all known wormwood allergens has recently been deciphered (Guideline on the clinical development..., 2008). The main native wormwood allergen Art vI is a highly glycosylated glycoprotein with a molecular weight of 24 to 28 kDa, has an unusual tertiary structure and the end portion of the molecule, the so-called “head and tail”, which explains its extraordinary biochemical properties (Incorvaia and Fuiano, 2013).

Different groups studied, sensitization to allergens from Art vI wormwood, Art v3, Timothy Phl p1, Phl p5, and Bet v1 birch had a similar distribution of the trait in most patients; no

statistically significant difference was found between these groups ( $p = 0.501$ ). The greatest sensitization was also detected in both groups to the major recombinant allergens of the wormwood Art vI-Art v3.

Also, when evaluating the results obtained by serological examination of patients' blood, we identified a statistically significant difference between the relative concentrations of major recombinant allergens of wormwood, ambrosia, timothy, and birch  $p < 0.001$  before and after sublingual immunotherapy. The distribution of signs was different from normal.

In the studied patients of group 1 (SLIT), the frequency of positive sensitization results to various recombinant major allergens Art vI, Art v3, Phl p1, Phl p5 and Bet v1 changed as follows: Art v 1 – from 17 (17.9%) to 11 (11.2%), Art v3 – from 6 (6.3%) to 4 (3.9%), Art v1-Art v 3 – from 43 (45.3%) to 27 (28.3%), Art v1,3-Bet v1 – from 13 (13.7%) to 8 (8.6%), Art v 1,3-Phl p1.5 – from 11 (11.6%) to 7 (7.2 %), Art v1,3-Bet v1-Phl p1.5 – from 5 (5.3%) to 3 (3.3%) (Figure 2).

For a comparative study of the immunological efficacy of SLIT and PIT, we studied the concentrations of major recombinant allergens before each course of ASIT. In patients of group 1, the level of specific IgE antibodies to the allergens of Art v1 wormwood to SLIT (Me, 25–75%) was 27.1 (11.2–35.8) Ku/l and corresponded to (Me, 25–75%) 3, 4 (3.1–3.9) class, after the 1st course SLIT (Me, 25–75%) was 23.6 (9.8–31.1) Ku/l and corresponded (Me, 25–75%) 3.4 (3.1–3.9) class, after the 2nd course SLIT (Me, 25–75%) was 18.1 (7.5–23.9) Ku/l and corresponded to (Me, 25–75%) 3.4 (3.1–3.9) class, after the 3rd course SLIT (Me, 25–75%) was 17.4 (7.2–22.9) Ku/l, corresponding to (Me, 25–75%) 3.4 (3.1–3.9) class. When evaluating the effectiveness of SLIT in patients with pollinosis for three courses, the concentration of Art v1 in serum was statistically significantly reduced 1.6 times (Friedman test:  $\chi^2 = 72.2$ ;  $p < 0.001$ ) (Figure 3).

The level of specific IgE antibodies to wormwood Art v3 allergens to SLIT (Me, 25–75%) was 8.0 (0.4–14.0) ku/l and corresponded to (Me, 25–75%) 1.3 (1, 1–3.9) class, after the 1st course SLIT (Me, 25–75%) was 7.3 (0.4–12.7) ku/l, corresponding to (Me, 25–75%) 1.3 (1.1–3.9) class, after the 2nd course SLIT (Me, 25–75%) was 5.6 (0.3–9.8) ku/l, corresponding to (Me, 25–75%) 1.3 (1.1–3.9) class, after the 3rd course SLIT (Me, 25–75%) was 5.4 (0.3–9.3) ku/l and corresponded (Me, 25–75%) 1.3 (1.1–3.9) class. Thus, the concentration of Art v3 in serum was statistically

significantly reduced by 1.5 times (Friedman test:  $x^2 = 64.1$ ;  $p < 0.001$ ).

The level of specific IgE antibodies to meadow grass allergens Phl p1 to SLIT (Me, 25-75%) was 1.0 (0.0-1.5) ku/l, corresponding to (Me, 25-75%) 0, 2 (0, 1-2.9) class, after the 1st course SLIT (Me, 25-75%) was 0, 9 (0.0-1.2) ku/l and corresponded to (Me, 25-75%) 0, 2 (0.1-2.9) class, after the 2nd course SLIT (Me, 25-75%) was 0.7 (0.0-1.0) ku/l, corresponding to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 3rd course SLIT (Me, 25-75%) was 0, 6 (0.0-0.9) ku/l and corresponded to (Me, 25-75%) 0, 2 (0.1-2.9) class. Thus, the concentration of Phl p1 in serum was statistically significantly reduced 1.6 times (Friedman test:  $x^2 = 42.4$ ;  $p < 0.001$ ) (Figure 4).

The level of specific IgE antibodies to meadow grass allergens Phl p5 to SLIT (Me, 25-75%) was 0, 2 (0.0-1.1) ku/l and corresponded to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 1st course SLIT (Me, 25-75%) was 0.15 (0.0-0.8) ku/l, corresponding to (Me, 25-75%) 0, 2 (0.1-2.9) class, after the 2nd course SLIT (Me, 25-75%) was 0.11 (0.0-0.7) ku/l, corresponding to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 3rd course SLIT (Me, 25-75%) was 0.10 (0.0-0.6) ku/l and corresponded to (Me, 25-75%) 0, 1 (0.1-1.9) class. That is, the concentration of Phl p 5 in serum was statistically significantly reduced by 1.5 times (Friedman test:  $x^2 = 36.0$ ;  $p < 0.001$ ).

The level of specific IgE antibodies to Bet v1 birch allergens to SLIT (Me, 25-75%) was 1.4 (0.2-2.1) ku/l and corresponded to (Me, 25-75%) 0, 2 (0, 1-2.9) class, after the 1st course SLIT (Me, 25-75%) was 1, 2 (0.0-1.9) ku/l, corresponding to (Me, 25-75%) 0, 2 (0.1-2.9) class, after the 2nd course SLIT (Me, 25-75%) was 0, 9 (0.0-1.2) ku/l and corresponded to (Me, 25-75%) 0, 2 (0.1-2.9) class, after the 3rd course SLIT (Me, 25-75%) was 0.8 (0.0-0.9) ku/l, corresponding to (Me, 25-75%) 0.2 (0.1-2.9) class, the concentration of Bet v1 in serum significantly decreased 1.5 times (Friedman test:  $x^2 = 56.1$ ;  $p < 0.001$ ).

After SLIT, in patients of group 1, the content of serum specific IgE antibodies to wormwood allergens Art v1 significantly decreased (Wilcoxon matched pairs test:  $z = 8.3$ ;  $p < 0.001$ ), to Art v3 (Wilcoxon matched pairs test:  $z = 7.5$ ;  $p < 0.001$ ), to meadow grass allergens Phl p1 (Wilcoxon matched pairs test:  $z = 4.1$ ;  $p < 0.001$ ), to Phl p5 (Wilcoxon matched pairs test:  $z = 3.4$ ;  $p < 0.05$ ), to Bet v1 birch allergens (Wilcoxon matched pairs test:  $z = 4.5$ ;  $p < 0.001$ ). In the study, the content of recombinant major allergens in the serum of patients with polysensitization showed

their statistically significant decrease after SLIT ( $p < 0.001$ ).

As in group 1 and group 2, when evaluating the results obtained by a serological method for examining patients' blood, a statistically significant difference was found between the relative concentrations of recombinant allergens of wormwood, timothy and birch ( $p < 0.001$ ) before and after the ICU, but which was less SLIT. The distribution of signs was also distinguishable from normal. Therefore, non-parametric research methods were used to evaluate the parameters.

In patients of group 2 (PIT), the frequency of positive sensitization results to various recombinant major allergens Art v1, Art v3, Amb a1, Phl p1, Phl p5 and Bet v1 changed as follows: Art v1 – from 9 (15.5%) to 7 (11.9%), Art v3 – from 3 (5.2%) to 2 (4.0%), Art v1-Art v3 – from 30 (51.7%) to 23 (39.8%), Art v1,3-Bet v1 – from 7 (12.1%) to 5 (9.3%), Art v1,3-Phl p1.5 – from 5 (8.6%) to 4 (6.6%), Art v1,3-Bet v1-Phl p1.5 – from 4 (6.9%) to 3 (5.3%) (Figure 5).

In the group of patients who received parenteral immunotherapy, the level of specific IgE antibodies to wormwood Art v1 allergens to PIT (Me, 25-75%) was 32.5 (13.4-42.9) Ku/l and corresponded to (Me, 25-75%) 3.4 (3.1-3.9) class, after the 1st course PIT (Me, 25-75%) was 29.5 (12.2-39.0) Ku/l, corresponding to (Me, 25-75%) 3.4 (3.1-3.9) class, after the 2nd course PIT (Me, 25-75%) was 24.6 (10.2-32.5) Ku/l, corresponding to (Me, 25-75%) 3.4 (3.1-3.9) class, after the 3rd course of PIT (Me, 25-75%) was 23.6 (9.8-31, 2) Ku/l and corresponded to (Me, 25-75%) 3.4 (3.1-3.9) class. When evaluating the effectiveness of PIT in patients with pollinosis during three courses, the concentration of Art v1 in serum significantly decreased 1.4 times (Friedman test:  $x^2 = 64.2$ ;  $p < 0.001$ ).

The level of specific IgE antibodies to wormwood Art v3 allergens before PIT (Me, 25-75%) was 8.8 (0.3-15.4) Ku/l and corresponded to (Me, 25-75%) 3.4 (3, 1-3.9) class, after the 1st course PIT (Me, 25-75%) was 8.7 (0.3-15.3) Ku/l, corresponding to (Me, 25-75%) 1, 3 (1.1-3.9) class, after the 2nd course of PIT (Me, 25-75%) was 7.2 (0.2-12.7) Ku/l and corresponded (Me, 25-75%) 0.3 (0.1-3.9) class, after the 3rd course of PIT (Me, 25-75%) was 6.8 (0.2-11.9) Ku/l, corresponding to (Me, 25-75%) 0.3 (0.1-3.9) class, the concentration of Art v3 in serum was statistically significantly reduced 1.3 times (Friedman test:  $x^2 = 48.6$ ;  $p < 0.001$ ).

The level of specific IgE antibodies to meadow grass allergens Phl p1 to PIT (Me, 25-

75%) was 1.5 (0.0-2.2) Ku/l and corresponded to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 1st course PIT (Me, 25-75%) was 1.2 (0.0-1.8) Ku/l, corresponding to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 2nd course of PIT (Me, 25-75%) was 0.04 (0.0-0.6) Ku/l and corresponded (Me, 25-75%) 3, 0, 1 (0.1-1.9) class, after the 3rd course SLIT (Me, 25-75%) was 1.1 (0.0-1.6) Ku/l Corresponding to (Me, 25-75%) 0, 2 (0.1-2.9) class, the concentration of Phl p1 in serum significantly decreased 1.3 times (Friedman test:  $\chi^2 = 29.6$ ;  $p < 0.001$ ).

The level of specific IgE antibodies to meadow grass allergens Phl p5 to PIT (Me, 25-75%) was 0.17 (0.0- 1.0) Ku/l and corresponded to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 1st course of PIT (Me, 25-75%) was 0.15 (0.0-0.9) Ku/l, corresponding to (Me, 25-75%) 0.2 (0.1-2.9) class, after the 2nd course SLIT (Me, 25-75%) was 0.14 (0.0-0.6) Ku/l, corresponding to (Me, 25 - 75%) 0.1 (0.08-1.9) class, after the 3rd course PIT (Me, 25-75%) was 0.14 (0.0-0.5) Ku/l and corresponded to (Me, 25-75%) 0, 1 (0.1-1.9) class. Thus, the concentration of Phl p5 in serum was statistically significantly reduced by 1.2 times (Friedman test:  $\chi^2 = 54.0$ ;  $p < 0.001$ ).

The level of specific IgE antibodies to Bet v1 birch allergens before PIT (Me, 25-75%) was 2.3 (0.0-2.9) Ku/l and corresponded to (Me, 25-75%) 0.2 (0, 1-2.9) class, after the 1st course of PIT (Me, 25-75%) was 2.1 (0.0-2.7) Ku/l, corresponding to (Me, 25-75%) 0, 2 (0.1-2.9) class, after the 2nd course PIT (Me, 25-75%) was 1.8 (0.0-2.1) Ku/l, corresponding to (Me, 25- 75%) 0.2 (0.1-2.9) class, after the 3rd course of PIT (Me, 25-75%) was 1.7 (0.0-1.9) Ku/l and corresponded to (Me, 25-75%) 0.2 (0.1-2.9) class. The serum Bet v1 concentration was statistically significantly reduced 1.5 times (Friedman test:  $\chi^2 = 56.1$ ;  $p < 0.001$ ). After PIT, the content of serum specific IgE antibodies to Art v1 wormwood allergens (Wilcoxon matched-pairs test:  $z = 8.4$ ;  $p < 0.001$ ) and Art v3 (Wilcoxon matched-pairs test:  $z = 7.6$ ;  $p < 0.001$ ), to meadow grass allergens Phl p1 (Wilcoxon matched-pairs test:  $z = 5.1$ ;  $p < 0.01$ ), to Phl p5 (Wilcoxon matched-pairs test:  $z = 3.8$ ;  $p < 0.05$ ), to birch allergens Bet v1 (Wilcoxon matched-pairs test:  $z = 5.4$ ;  $p < 0.001$ ).

As it is known, a significant clinical task in allergology for polysensitization and cross-allergy is to make an accurate diagnosis. For diagnostic accuracy and optimization of therapy, in particular immunotherapy, the development of recombinant allergens was an important step in medicine (Nelson, 2016; Pauli *et al.*, 2008; Ferreira, 1996; Valenta *et al.*, 2010).

Scientists of the Research Institute of Molecular Biology V.A. Engelhard, O. Smoldovskaya, G. Feyzkhanova, and their co-authors (2016) were studied in a multicenter comparative study of patients with hypersensitivity to birch pollen and cat dander using biological microchips, as well as skin scarification samples. As a result of the work, it was established that the diagnostic accuracy with the use of recombinant allergens was higher compared to skin test samples (Smoldovskaya *et al.*, 2016). An important conclusion and our study show that among all inhaled allergens, the highest rate relates to wormwood, which significantly decreased after the courses ASIT. Similar data were obtained in domestic surveys in epidemiological studies, where the main cause of seasonal allergy in Kazakhstan was pollen of weeds (Saltabayeva *et al.*, 2017).

Therefore, further study of allergic anamnesis and skin scarification tests with other allergens that have common allergenic properties, including an assessment of pollen, timothy and birch pollen reactivity, is needed to study cross-section properties with recombinant allergens, which is necessary to determine a more accurate profile of specific IgE reactivity to recombinant allergens in patients living in the north of Kazakhstan. Continuing research to determine whether the recombinant allergens match the spectrum of allergen-specific antibodies detected in this population will facilitate the use of recombinant allergens for diagnosing, monitoring, and selecting the right treatment with specific immunotherapy for patients with pollinosis in our region with multiple pollen influences.

#### 4. CONCLUSIONS:

Upon completion of the three courses of PIT, a statistically significant ( $p < 0.001$ ) decrease in the concentration of major recombinant allergens in the blood serum was detected, but which was relatively inferior to the SLIT group. The data obtained confirm the high efficiency of SLIT and its positive effect on the reduction of sensitization in patients with pollinosis compared with the results of the parenteral immunotherapy group.

Thus, the presence of a positive response from patients to major allergens of pollen from Art v1 wormwood, Art v3, Timothy Phl p1, Phl p5 and Bet v1 birch with cross allergy decreased after three courses of immunotherapy in group 1 (SLIT) 1.5 times and in group 2 (PIT) 1.3 times.

Analysis of the effects of ASIT in patients

with positive *in vitro* results on major recombinant allergens showed that after a three-year course of ASIT in two groups, a decrease in serum concentration of major recombinant allergens was observed, but more significant results were obtained in the group of patients who took the sublingual type of immunotherapy compared with the parenteral immunotherapy group ( $p < 0.001$ ).

## 5. ETHICAL APPROVAL

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study.

## RESUMO

A bactéria *Escherichia coli* é um dos melhores organismos de vida livre estudados em profundidade. É uma espécie surpreendentemente diversificada, já que algumas cepas de *E. coli* vivem no intestino de animais como comensais inofensivos, enquanto outros genótipos distintos, como uma *E. coli* enteropatogênica ou enterohemorrágica, por exemplo, causam morbidade e morte marcadas como patógenos intestinais humanos. Este estudo teve como objetivo desenvolver e validar um ensaio de PCR para uma região gênica conhecida e suspeita de fator de virulência (*kpsMT*) de *E. coli* uropatogênica para determinar a distribuição do gene e seu papel no desenvolvimento de doenças clínicas do sistema urinário. Um total de 25 amostras de urina foram coletadas de pacientes com infecção do trato urinário (ITU) dos hospitais Azadi e Kirkuk, na cidade de Kirkuk, Iraque. Foram coletadas amostras de ambos os sexos e idades diferentes de pacientes com suspeita de infecção do trato urinário de acordo com as manifestações clínicas e sintomas diagnosticados pelo médico examinador. As amostras foram cultivadas e as amostras positivas foram submetidas ao teste IMViC para identificar as bactérias *E. coli* e, posteriormente, identificadas usando o sistema compacto Vitek 2. Entre 25 amostras, 24 (96%) apresentaram resultados positivos para o crescimento cultural bacteriano. Dessas, 17 (68%) foram identificadas como *Escherichia coli*. Do total de 17 isolados, 14 tinham infecção no trato urinário leve e 3 tinham urosepsia. O gene *kpsMT* estava presente em 14 isolados (82,3%), incluindo 11 (78,5%) isolados de infecção no trato urinário leve e 3 (100%) isolados de pacientes com urosepsia. Concluiu-se que *Escherichia coli* é a mais prevalente em amostras de infecção no trato urinário na urina. Devido à abundância do gene *kpsMT* na *Escherichia coli* uropatogênica (UPEC), esse gene desempenha um papel importante no desenvolvimento de ITU se não for tratado corretamente e rapidamente; casos leves de ITU podem se transformar em urosepsia.

**Palavras-chave:** *Escherichia coli*, uropatogênico, IMViC, Capsule, gene *kpsMT*.

## ABSTRACT

The bacterium *Escherichia coli* is one of the best free-living organisms studied in depth. It is a surprisingly diverse species, since some strains of *E. coli* live in the intestine of animals as harmless commensals, while other distinct genotypes, such as an enteropathogenic or enterohemorrhagic *E. coli*, for example, cause morbidity and death marked as human intestinal pathogens. The purpose of this study was to develop and validate a PCR assay for a known and suspected uropathogenic *E. coli* virulence factor (*kpsMT*) gene region to determine the distribution of the gene and its role in the development of clinical diseases of the urinary system. A total of 25 urine samples were collected from patients with urinary tract infection (UTI) at Azadi and Kirkuk hospitals in the city of Kirkuk, Iraq. Samples of both genders and different ages were collected from patients with suspected urinary tract infection according to the clinical manifestations and symptoms diagnosed by the examining physician. The samples were cultured and positive samples were subjected to the IMViC test to identify *E. coli* bacteria and subsequently identified using the Vitek 2 compact system. Among 25 samples, 24 (96%) showed positive results for bacterial cultural growth. Of these, 17 (68%) were identified as *Escherichia coli*. Of the total of 17 isolates, 14 from patients with mild urinary tract infection, and 3 from patients with Urosepsis. The *kpsMT* gene was present in 14 isolates (82.3%), including 11 (78.5%) isolates from patients with mild urinary tract infection, and 3 (100%) isolates from patients with Urosepsis. It was concluded that *Escherichia coli* is the most prevalent

in urine tract infection samples. Due to the abundance of the *kpsMT* gene in uropathogenic *Escherichia coli* (UPEC), this gene plays an important role in developing UTI if it is not treated correctly and quickly; mild cases of UTI can turn into Urosepsis.

**Keywords:** *Escherichia coli*, Uropathogenic, IMViC, Capsule, *kpsMT* gene.

## المخلص

بكتيريا الإشريكية القولونية هي واحدة من أفضل الكائنات الحية التي تمت دراستها بعمق. هذه الأنواع تكون متغيرة فيما بينها بشكل مثير للدهشة، حيث أن بعض سلالات الإشريكية القولونية تعيش في الأمعاء كعلاقة تبادل منفعة، بينما الانماط الجينية الأخرى، مثل الإشريكية القولونية الممرضة المعوية أو الإشريكية القولونية النزفية، على سبيل المثال، تسبب الأمراض والوفيات والذي يشار إليها بمسببات الأمراض المعوية البشرية. الغرض من هذه الدراسة هو لتطور وتحقق اختبار تفاعل البوليميراز المتسلسل لمنطقة معلومة ومشتبهة لجين عامل الضراوة *kpsMT* لتحديد معرفة توزيع هذا الجين ودوره في تطوير الأمراض السريرية للجهاز البولي. تم جمع 25 عينة بول من مرضى يعانون من عدوى المسالك البولية في مستشفيات آزادي وكركوك في مدينة كركوك، العراق. تم جمع عينات من كلا الجنسين ومن أعمار مختلفة من المرضى الذين يشتبه في إصابتهم بالتهاب المسالك البولية وفقاً للمظاهر والأعراض السريرية التي تم تشخيصها من قبل الطبيب الفاحص. تم زرع العينات والعينات الوجيهة للنمو أجري لها اختبار IMViC لتحديد بكتيريا الإشريكية القولونية ومن ثم شُخصت باستخدام نظام Vitek 2 compact system. من بين 25 عينة، أظهرت 24 عينة (96%) نتائج إيجابية للنمو البكتيري، حيث تم تحديد 17 (68%) منها على أنها بكتيريا الإشريكية القولونية. في هذه الدراسة، من أصل 17 عينة كان 14 من المصابين بالتهاب مجرى البول البسيط و 3 من المصابين بآنتان المسالك البولية، كان الجين *kpsMT* موجوداً في 14 عينة (82.3%) بما في ذلك 11 (78.5%) من المصابين بالتهاب مجرى البول البسيط و 3 (100%) من مرضى آنتان المسالك البولية. خلُصت هذه الدراسة إلى أن الإشريكية القولونية هي الأكثر انتشاراً في عينات المسالك البولية. بسبب وفرة الجين *kpsMT* في سلالات بكتيريا الإشريكية القولونية البولية (UPEC) حيث يلعب دوراً مهماً في تطوير التهاب المسالك البولية إذا لم يتم التعامل معها بشكل صحيح وسريع، فقد تتطور الحالات البسيطة من التهاب المسالك البولية إلى آنتان المسالك البولية.

**الكلمات المفتاحية:** الإشريكية القولونية، مسببة لأمراض الجهاز البولي، IMViC، الكبسول، جين *kpsMT*.

## 1. INTRODUCTION:

The bacterium *Escherichia coli* is one of the best free-living organisms studied in depth. It's a surprisingly diverse species as well since some *E. coli* strains live in animal intestines as harmless commensals, whilst other distinct genotypes, including enteropathogenic, enterohemorrhagic, enteroinvasive, enterotoxigenic and enteroaggregative *E. coli* causes marked morbidity and death as human intestinal pathogens. Extraintestinal *E. coli* are another diverse category of life-threatening pathogenic bacteria. This latter group of pathogens includes separate clonal groups responsible for sepsis of neonatal meningitis and infections of the urinary tract. The uropathogenic group accounts for 70–90% of the 7 million cases of acute cystitis and 250,000 cases of pyelonephritis reported in the United States annually (Hooton and Stamm, 1997).

The extraintestinal *E. coli* differs from diarrheal pathogens because when they enter the urinary tract, bloodstream, or cerebrospinal fluid, they can act as either harmless human intestinal inhabitants or serious pathogens (Welch *et al.*, 2002). Within each of these broad groups are sets of strains known as pathotypes that share common virulence factors and elicit similar pathogenic outcomes (Marrs *et al.*, 2005). Several pathotypes of diarrheagenic *E. coli* give rise to gastroenteritis, but rarely cause disease outside of the intestinal tract. ExPEC, on the other hand, has

maintained the ability to exist in the intestine without consequence but can spread and colonize different host niches, including the blood, central nervous system, and urinary tract, leading to disease (Wiles *et al.*, 2008). Urosepsis refers to severe infection of the urinary tract and/or the male genital tract (e.g., prostate) with features consistent with systemic inflammatory response syndrome (Kalra and Raizada, 2006).

The severity of disease conditions that are associated with UTI depends on multiple UPEC VFs and host susceptibility. A wide range of VFs genes such as adhesins (*fim*, *sfa*, *afal*, *iha*, *papC*, *tsh*, and *papGI*, -II, and also -III), iron acquisition systems (*irp2*, and *iuc*, *iroN*), protectins (*kpsMT*, and *iss*, *ompT*), and genes encoding for toxins (*astA*, *cnf1*, *hlyA*, *usp*, *set*, *vat*, and *cva/cvi*) are involved in the pathogenicity conditions of UPEC (Abe *et al.*, 2008; Chiou *et al.*, 2010). Pathogenic bacteria produce a thick, mucus-like layer of polysaccharide, called capsule coat antigenic proteins on the bacterial surface, otherwise, induce an immune response and lead to the destruction of the bacteria. Polysaccharides capsules are water-soluble, usually acidic, thermo-stable, and have molecular weights on the order of 100–2000 kDa, linear and consist of regularly repeating subunits of one to six monosaccharides. There is massive structural diversity; nearly two hundred different polysaccharides are produced by *E. coli* alone (Yun *et al.*, 2014). The gene *kpsMT* encodes for the K antigen capsule, which Enables UPEC to

evade the host's innate immune defenses (e.g., the complement system) (Justice *et al.*, 2006).

This study aimed to develop and validate a PCR assay for a known and suspected uropathogenic *E. coli* virulence factor (*kpsMT*) gene region to determine the distribution of the gene and its role in the development of clinical diseases of the urinary system.

## 2. MATERIALS AND METHODS:

### 2.1. Sample collections and strain identification assay

A total of 25 midstream urine samples were collected from hospitalized UTI patients of different ages and gender from local hospitals in Kirkuk / Iraq. Permission to conduct this study was issued by the Health institutional, and the collection of samples of individuals was carried out by under public health technician supervision. All participants have agreed to participate in this study, which was conducted from September 2019 to December 2019. All 25 specimens have been cultured on Blood agar, MacConkey agar, and Eosin methylene blue agar. The preparation of biochemical tests to confirm differentiation of *E. coli* from other lactose fermenters among Enterobacteriaceae was done by the following: IMViC test include: indole positive, methyl red positive, negative in the Voges-Proskauer, and, Simmons citrate also urease production, (MacFaddin, 2002). The results of biochemical tests for the final identification of *E. coli* were based on growth morphology on EMB agar and Vitek 2 compact system.

### 2.2. Primer design

The primers used to amplify *kpsMT* gene were designed using (Pick Primers) tool in the National Center for Biotechnology Information (NCBI) website and were manufactured by the Alpha company (Canada). The primers information is described in Table 1.

### 2.3. Extraction of Deoxyribonucleic acid

Bacterial chromosomal DNA of *E. coli* isolates was extracted by Geneaid™ DNA Isolation Kit based on the manufacturer's instructions. The Deoxyribonucleic acid has been evaluated by a nanodrop system that tuned to 260/280nm. Then the DNA was preserved at temperature (-20°C) till further use.

### 2.4. Polymerase chain reaction analysis

The PCR assay was performed to detect the Virulence gene (Table 1), were primer *kpsMT* gene that encodes for capsule in *Escherichia coli* based on specified primers. The virulence gene was screened by PCR technique. For the detection this gene; The Chromosomal DNA extracted from all isolates were subjected to primers by monoplex PCR. The mixture of PCR for each primer with final volume 20 µl/reaction and The protocol used depends on Master Mix(AccuPower® PCR PreMix (Bioneer, Korea) instructions. Each monoplex PCR reaction mixture consisted of 2µl Forward Primer (10 picomole), 2µl Reverse Primer (10 picomole), 9µl De-ionized water, and 7µl the DNA of the isolates were added into the AccuPower® Taq PCR PreMix tubes that contain (Taq DNA polymerase, dNTPs, KCl, MgCl<sub>2</sub>, and buffer). All PCR components were assembled in PCR tube and mixed by micro-centrifuge at 50 rcf (850 rpm) for 10 second. The PCR reactions began with a 94°C Denaturation for 5 minutes and were terminated with 72°C extension for 3 minutes and a 4°C hold and The Condition for other steps for this primer consisted of 25 cycles of a denaturation at 94°C for 2 min annealing at 65°C for 1 min then extension at 72°C for 2 min in the thermal cycler based on the primer design designated T<sub>m</sub> and some modifications for optimization (Qadir *et al.*, 2018).

### 2.5. PCR product analysis

PCR product has been examined via Electrophoresis instrument in a 0.9% agarose gel substance with the use of TBE buffer, which stained by Ethidium Bromide. The product was visualized and documented under ultra-violet trans-illuminator (Mishra *et al.*, 2010).

## 3. RESULTS AND DISCUSSION:

Characterization of *E. coli* strains is essential for both epidemiological and clinical implications. Pathogenic behavior is predicted both by repertoire of the virulence factor and by phylogenetic background (Duriez *et al.*, 2001; Picard *et al.*, 1999). Urinary tract infection can, in time, develop into a real threat, capable of expanding to renal failure. Enhanced knowledge of the virulence characteristics of the causative organism allows the clinician to predict the evolution of infection within the host. In the current study, From 25 urine samples, 18 (72%) were from female, and 7 (28%) from male, 17 (68%) isolates of *E. coli*, 4 (16%) isolates *Klebsiella pneumonia*,

3 (12%) isolates *Proteus mirabilis* and one sample (4%) showed no growth, the profile of the causative agents are listed in Table 2. Among *E. coli* causing infection, out of 17 isolates, 12 (70.5%) were taken from female patients, and 5 (29.4%) were from male patients, and this rate was close to the results of (Qadir *et al.*, 2018) in Wasit/Iraq and (Aljebory and Mohammad, 2019) in Kirkuk/Iraq as they showed that *E. coli* was the most predominant cause of UTI and that females were more susceptible to it than male. Moreover, the female to male ratio concerning Mild-UTI/Urosepsis is described in Table 3.

Recently, several different prevalence rates of UPEC strains related to UTIs have been described in different countries (Derakhshandeh *et al.*, 2015), (Mohajeri *et al.*, 2014), (Lee *et al.*, 2013). The capsule-encoding gene, *kpsMT*, is commonly prevalent in UPEC strains associated with pyelonephritis than in strains associated with other UTIs (Sussman, 1997). In the current study, the gene *kpsMT* was investigated due to its role in evading the immune system, hence causing severe conditions of UTI. The study finding of this gene have shown that 14 (82.3%) isolates were carrying *kpsMT* gene including 11 (78.5%) isolates from Mild-UTI, and 3 (100%) isolates from Urosepsis patients which leads to the assumption that even the (Mild-UTI) patients are susceptible to severe UTI conditions or Urosepsis if not managed in a short period. A demonstration of the assay is shown in Figure 1. The distribution of *kpsMT* gene in relation to Mild-UTI/Urosepsis is shown in Table 4.

Fever, flank pain, dysuria, frequency, urgency, and suprapubic pain has been the observed clinical symptoms of our study and can be compared with the Bent's report (Bent *et al.*, 2002). Several studies have had an approaching result to this study; there was a report of *kpsMT* gene's existence to be (84.4%) among Uropathogenic *E. coli* isolates revealed by (Yun *et al.*, 2014), similar results were shown by (Aljebory and Mohammad, 2019) in Kirkuk/Iraq as they found that (76.4%) of the isolates were carrying *kpsMT* gene, (Qadir *et al.*, 2018) in Wasit/Iraq and (Yamamoto, 2007) in Japan had close results to this study. However, the results of researches done by (Alqasim *et al.*, 2020) and (Johnson and Stell, 2000) did not match with this study as they revealed (51.7%) and (63%) respectively. However, these strains need to be sequenced by 16S rRNA or RAPD-typing for further studies as recommended by Salih and Shafeek, 2019; Banoon *et al.*, 2019; Aldujaili and Banoon, 2020).

## 4. CONCLUSIONS:

*Escherichia coli* are the most prevalent among UTI urine samples. Due to the abundance of the gene *kpsMT* in UPEC, there is a role of this gene in developing UTI. For the same reasons above, mild UTI cases can develop into Urosepsis if not treated accordantly and quickly.

## 5. ACKNOWLEDGMENTS:

I would like to show my appreciation to Karwan Azeez Mohammed Shaexany at Kirkuk University, College of Science, Department of Biology for collecting the samples and designing the PCR primers, due to his support, this research was doable.

## RESUMO

O método simples, rápido, econômico e ambientalmente amigável foi desenvolvido para a determinação espectrofotométrica do cloridrato de ranitidina (R-HCl) em amostras farmacêuticas após extração pelo método do ponto de névoa. O método baseado na redução de Fe(III) pelo cloridrato de ranitidina em Fe(II), que posteriormente reagiu com o ferricianeto para formar produtos coloridos em (pH 4,0), o surfactante Triton X-114 foi usado como um extrator do cloridrato de ranitidina. A linearidade da curva de calibração foi mantida a partir de concentrações entre 0,5-60,0 µg/mL na absorção máxima de 693 nm. Fatores necessários para condições de reação, incluindo pH, FeCl<sub>3</sub> e K<sub>3</sub>[Fe(CN)<sub>6</sub>], volume de surfactante, temperatura, tempo e ordem de adição foram investigados. A análise de regressão indica que o coeficiente de correlação foi de 0,9998 e a capacidade de absorção molar foi de 0,46·10<sup>4</sup> L/mol.cm. Os limites de detecção e quantificação foram de 0,475 e 1,567 µg/mL, respectivamente. O limite de confiança do declive e o limite de confiança do intercepto a 95% foram 0,0147 ± 0,00015 e 0,0642 ± 0,01033. A sensibilidade de Sandell também foi calculada e foi encontrado 0,0680 µg/cm<sup>2</sup>. O fator de pré-concentração foi de 50,0%. Os estudos de validação para três concentrações diferentes (5,0, 10,0 e 30,0) µg/mL de cloridrato de ranitidina deram desvios padrão relativos entre 0,142-0,728 e a porcentagem de recuperações variou de 98,780 ± 0,719 – 99,840 ± 0,142. O método proposto foi aplicado com sucesso para a determinação do cloridrato de ranitidina em alguns de seus produtos farmacêuticos, com recuperação entre 99,108–99,808 e RSD% entre 0,012– 0,031. Os resultados obtidos com o método proposto o tornam adequado para uso na determinação do cloridrato de ranitidina em sua forma de dosagem a granel e em comprimidos.

**Palavras-chave:** *Ponto de névoa; Ranitidina; Espectrofotometria.*

## ABSTRACT

The simple, rapid, economical, and environmentally friendly method was developed for spectrophotometric determination of ranitidine hydrochloride (R-HCl) in pharmaceutical samples after extraction by the cloud point method. The method based on the reduction of Fe(III) by ranitidine hydrochloride to Fe(II), which subsequently reacted with ferricyanide to form colored products at (pH 4.0), then Triton X-114 surfactant was used as an extractant for ranitidine hydrochloride. The linearity of the calibration curve was maintained from concentrations between 0.5–60.0 µg/mL at the maximum absorption 693 nm. Factors required for reaction conditions including pH, FeCl<sub>3</sub>, and K<sub>3</sub>[Fe(CN)<sub>6</sub>] concentration, the volume of surfactant, temperature, time, and order of addition were investigated. Regression analysis indicates that the correlation coefficient was 0.9998 and the molar absorptivity was 0.46·10<sup>4</sup> L/mol.cm. Detection and quantification limits were 0.475 and 1.567 µg/mL, respectively. The confidence limit of slope and the confidence limit of the intercept at 95% were 0.0147 ± 0.00015

and  $0.0642 \pm 0.01033$ . Sandell's sensitivity was also calculated and it was found  $0.0680 \mu\text{g}/\text{cm}^2$ . The preconcentration factor was 50.0%. Validation studies for three different concentrations (5.0, 10.0 and 30.0)  $\mu\text{g}/\text{mL}$  of ranitidine hydrochloride gave relative standard deviations between 0.142–0.728 and the percentage recoveries ranged from  $98.780 \pm 0.719$  –  $99.840 \pm 0.142$ . The proposed method was successfully applied for the determination of ranitidine hydrochloride in some of its pharmaceutical products with recovery between 99.108–99.808 and RSD% between 0.012– 0.031. The results obtained from the proposed method make it suitable to use in the determination of ranitidine hydrochloride in its bulk and tablet dosage form.

**Keywords:** Cloud point; Ranitidine; Spectrophotometry.

## المخلص

تم تطوير طريقة بسيطة، سريعة، اقتصادية وصديقة للبيئة لتقدير الرانيتيد هيدروكلورايد في الأقراص الدوائية بعد استخلاصه بطريقة نقطة الغيمة. الطريقة تعتمد على اختزال الحديد الثلاثي بواسطة الرانيتيد هيدروكلورايد إلى الحديد الثنائي والذي بدوره يتفاعل مع فروسانييد الحديد لتكوين ناتج ملون عند دالته حامضية 4 بعدها استخدم تريتون X-114 لاستخلاص الرانيتيد هيدروكلورايد. الخطية لمنحنى المعايرة تم الحصول عليها عند تراكيز تراوحت بين 0.5 و 60.0 مايكروكروم /مل عند امتصاصية عظمى 693 نانومتر. تم اختيار العوامل المطلوبة لظروف التفاعل بما في ذلك الدالته الحامضية، تركيز  $\text{FeCl}_3$  و  $\text{K}_3[\text{Fe}(\text{CN})_6]$ ، حجم مخفض الشد السطحي، درجة الحرارة، الوقت وتسلسل الإضافات. يشير تحليل الانحدار إلى أن معامل الخطية 0.9998 والامتصاص المولاري  $0.46 \times 10^4$  لتر /مول. سم. حد الكشف وحد الكشف الكمي كانت 0.0147 و  $0.0642 \pm 0.01033$  و 0.475 و 1.567 مايكروكروم / مل على التوالي. حد الثقة للميل والقطع عند حدود ثقة 95% كانت  $0.0147 \pm 0.00015$  و  $0.0642 \pm 0.01033$  على التوالي. تم أيضاً دراسة حساسية ساندل وقد وجد أنها تساوي 0.0680 مايكروكروم /سم<sup>2</sup>. عامل التركيز المسبق كان 50.0%. الدراسة التقييمية لثلاث تراكيز من الرانيتيد هيدروكلورايد (5.0، 10.0 و 30.0) مايكروكروم /مل أعطت انحراف قياسي نسبي منوي يتراوح بين (0.142 و 0.728) والاستيعابية المئوية بين  $98.780 \pm 0.719$  -  $99.840 \pm 0.142$ . الطريقة المقترحة يجعل منها طريقة مناسبة لاستخدامها في تقدير الرانيتيد هيدروكلورايد في المستحضرات الصيدلانية.

الكلمات الرئيسية: غيمة. رانيتيد. قياس الطيف الضوئي.

## 1. INTRODUCTION

Ranitidine hydrochloride (R-HCl) has the chemical name, according IUPAC ((E)-1-N'-[2-[[5-[(dimethylamino)methyl]furan-2-yl]methylsulfany]ethyl]-1-N-methyl-2-nitroethene-1,1-diamine hydrochloride and the trade name is Zantac. The structure of ranitidine with the formula ( $\text{C}_{13}\text{H}_{22}\text{N}_4\text{O}_3\text{S} \cdot \text{HCl}$ ) explained in Figure 1 (Keith, 2000).

**Figure 1.** Structure of ranitidine hydrochloride.

R-HCl is classified under the medication that has the ability to act as histamine  $\text{H}_2$ -blocker on parietal cells in a stomach leading to decrease secretion of acid by these cells. Generally, ranitidine used to duodenal ulcer treatment and also in the management of the hypersecretory condition. R-HCl, in many cases, used in the treatment of gastro esophageal reflux and peptic ulcer diseases (Zhang *et al.*, 2015; Narayana *et al.*, 2010; Darwish *et al.*, 2008).

R-HCl has the ability to coordinate with the transition metals and also to form ion-pair

complexes with dyes in the acidic medium due to the presence of amine group and thioether sulphur in its structure (Kiszkziel *et al.*, 2015; El-Yazbi *et al.*, 2003; Pérez-Ruiz *et al.*, 2001).

In brief, CPE (*cloud point extraction*) at optimized temperature (above the cloud point temperature) cloudy aqueous solutions contain non-ionic surfactant will have formed lowering the solubility of surfactant in water, thereby formation of two phases, aqueous poor phase and a small volume of organic-rich phase. The analyte will be partitioning between these two phases related to its hydrophobicity (Bai *et al.*, 2001; Takagai and Hinze, 2009; Hinze and Pramauro, 1993; Stalikas, 2002; Delgado *et al.*, 2004).

In CPE, phase separation was maintained due to the formation of the micellar phase by using appropriate surfactant under optimized conditions. These micelles will aggregate at the CMC (*critical micelles concentration*), which is the minimum concentration of surfactant. CPE was considered environmentally friendly due to the use of a small amount of solvent and non-volatile surfactant and non-toxic. In addition to that in CPE the analyte can be determined and the matrix can be removed in one step (Jia *et al.*, 2008).

Many analytical methods were reported for determination of R-HCl, some of these methods include spectrophotometry, flow injection, voltammetry, potentiometry, conductometric, HPLC, Redox reaction, ESI-LC-MS/MS and TLC

(Baqir *et al.*, 2014; Moldovan and Aboul-Enein, 2012; Basavaiah and Nagegowda, 2004; Elbashir and Merghani, 2018; Issa *et al.*, 2005; Frag *et al.*, 2011; Ahamed *et al.*, 2006; Vicentini *et al.*, 2016; Tang *et al.*, 2007; Merghani and Elbashir, 2018; Bindewald *et al.*, 2018; Sharma *et al.*, 2011; Alamgir *et al.*, 2017; Kantariya *et al.*, 2013; Amin *et al.*, 2003; Bellorio *et al.*, 2013).

The present study aimed to develop a new, economic, friendly, and rapid cloud point extraction coupled with a spectrophotometric method for extraction and determination of ranitidine hydrochloride from pharmaceutical preparations.

## 2. MATERIALS AND METHODS

### 2.1. Reagent and materials

The standard of ranitidine hydrochloride (99.0%) supplied from Merck was prepared by dissolving 0.01 g in distilled water, then complete the volume to 100 mL in a volumetric flask. Triton X-114 (99.9%) purchased from Sigma-Aldrich company was prepared by diluting 10 mL in distilled water with gently heating at 30 °C for complete dissolving, then complete the volume to the mark with 100 mL distilled water in a volumetric flask.

Ferric chloride (99.9%) obtained from the BDH company was prepared by dissolving 0.0162 g in 1 mL concentrated HCl and then made up to 100 mL volumetric flask with distilled water.

Sodium hydroxide (99.0%) supplied from BDH company was prepared by dissolving 0.4 g in distilled water and complete to the mark in 100 mL volumetric flask with distilled water. Potassium ferricyanide (99.0%) provided from Sigma-Aldrich was prepared by dissolving 0.0329 g in distilled water and complete to the mark in 100 mL volumetric flask with distilled water.

HCl supplied from BDH was prepared by diluting 0.877 mL in distilled water and complete to the mark in 100 mL distilled water in a volumetric flask.

### 2.2. Apparatus

In SHIMADZU double-beam spectrophotometer (UV-1800) was used for absorbance measurements, pH-meter, (HANNA™) for pH measurement, shaking water bath (JULABO™) was used for temperature control throughout carrying the experiments of cloud point extraction.

### 2.3. Sample preparation

Ten tablets of each different product that contain 150 mg of R-HCl were grinded and mixed well to obtain bulky homogenous powders from each product. Weight equivalent to 0.01 g of pure R-HCl has been taken and dissolved in distilled water, then filtered and transferred to 100 mL volumetric flask and complete the volume to the mark to prepare 100 µg/mL. From these stock solutions of different products dilute solutions were prepared for applying the proposed method (Basavaiah and Nagegowda, 2004).

### 2.4. General procedure for cloud point extraction

Different volumes of standard solutions were added in 10 mL centrifugal screw tubes ranging from 0.05–6.0 mL of 100 µg/mL which corresponding to 0.5–60.0 µg/mL of ranitidine-HCl. Giving sequence, 0.8 mL of  $8.0 \cdot 10^{-3}$  M  $\text{FeCl}_3$  solution were added for each tube followed by addition of 0.6 mL of  $6.0 \cdot 10^{-5}$  M  $\text{K}_3\text{Fe}(\text{CN})_6$  solution and adjusted the pH of solutions (pH 4.0) by using 0.1 M NaOH and/or 0.1 M HCl.

For cloudy solutions, 0.7 mL of Triton X-114 was added to the final solution and completed to the mark with 10 mL distilled water, then incubated for 20 min in water bath at 50 °C, then cooled. The aqueous layer was removed by microsyringe, and the organic-rich phase was diluted with 0.5 mL ethanol. The absorbance of each solution was measured at  $\lambda_{\text{max}}$  693 nm against a blank solution (Khammas and Ahmad, 2016).

## 3. RESULTS AND DISCUSSION

### 3.1. Absorption spectra

R-HCl (50 µg/mL),  $\text{FeCl}_3$  ( $1.0 \cdot 10^{-3}$  M),  $\text{K}_3[\text{Fe}(\text{CN})_6]$  ( $1.0 \cdot 10^{-3}$  M) solutions and the colored complex were scanned in the UV-Vis from 190–1100 nm against the blanks for spectral study. It was found that ranitidine R-HCl,  $\text{FeCl}_3$ ,  $\text{K}_3[\text{Fe}(\text{CN})_6]$  and Triton X-114 gave maximum absorption at 308 nm, 290 nm, 303 nm, and 224 nm respectively. While the colored solution for R-HCl after addition of  $\text{FeCl}_3$  and  $\text{K}_3[\text{Fe}(\text{CN})_6]$  in the presence of Triton X-114 gave maximum absorption at 693 nm. This absorption for the colored product was adopted for further optimization in Figure 2.

### 3.2. Optimization of experimental conditions

Cloud point extraction affected by a various factor that can improve the extraction thereby the efficiency of the proposed method, for those such parameters like pH, incubation time, the temperature of equilibrium, Triton X-114 volume,  $\text{FeCl}_3$ , and  $\text{K}_3[\text{Fe}(\text{CN})_6]$  concentrations were investigated by the classical optimization. Triton X-114 selected due to its low cloud point temperature (22 to 23 °C) and low critical micelles concentration (~0.2 mM) (Santaladchaiyakit, and Srijaranai, 2012).

#### 3.2.1. Effect of pH

Extraction efficiency was widely affected by pH value, thereby affecting the absorbance of organic rich-phase. Thus, pH of the solution was study in the range of 2.0–10.0 at 50 °C for 20 min at R-HCl within concentration of 50  $\mu\text{g/mL}$ . All other parameters kept constant as in the described procedure. From the results in Figure 3, was chosen pH 4.0 due to the highest response.

Change in the pH generally affects the ionization form of the analyte leading to change water solubility and the extractability of analyte. pH adjustment should be optimized to ensure that the neutral molecular form of the drug was present before the CPE step also. The pH value affects the partitioning of analyte in the CPE. It was clearly explained in Figure 3 that in pH 4.0 had the highest response, and afterthought, this point the pH decreases. Thus, pH 4.0 was selected for optimization.

#### 3.2.2. Effect of ferric chloride concentration

Fe (III) salt like  $\text{FeCl}_3$  can be used as oxidant agent for the determination of some compound to form oxidizing colored product. Fe (II) was used as a reduced form of Fe(III), for that the concentration of  $\text{FeCl}_3$  on the formation of the colored product complex was investigated by adding the different volume of  $1.0 \times 10^{-3}$  M  $\text{FeCl}_3$  solution ranged from (0.1–1.0) mL at pH 4 and keeping the other condition constant (Figure 4). R-HCl reduce Fe (III) and forming Fe (II) which is subsequently reacted with  $\text{K}_3[\text{Fe}(\text{CN})_6]$  to form the blue product which measured at 693 nm. From Figure 4, the highest absorption was maintained when the concentration of  $\text{FeCl}_3$  was  $8.0 \times 10^{-5}$  M (0.8 mL of  $1.0 \cdot 10^{-3}$  M in 10 mL final aqueous solution). So this concentration was chosen for further optimization.

#### 3.2.3. Effect of potassium ferricyanide

Some of the oxidizing agents have an important effect on the coupling reaction between ligand and the metal. To this reason, effect of potassium ferricyanide was tested by the addition of various volumes of  $\text{K}_3[\text{Fe}(\text{CN})_6]$  ranged from (0.1–1.0) mL (Figure 5).

The maximum signal obtained was at volume 0.6 mL, which is related to the concentration of  $1.0 \times 10^{-5}$  M  $\text{K}_3[\text{Fe}(\text{CN})_6]$  in 10 mL final solution, for that this concentration was adopted for optimization.

#### 3.2.4. Effect of surfactant amount

The efficiency of extraction in CPE highly depended on the concentration of surfactant which is also affected the preconcentration factor, Thus, different volume of surfactant ranged from (0.1–2.0) mL of 10% Triton X-114 was tested. We can see the results in Figure 6.

The optimized volume of the surfactant was 0.7 mL, as explained in Figure 6. Below this point, it was difficult to separate the surfactant rich phase due to the small volume of rich phase relative to the total volume of solution. The other hand, above this point the volume of surfactant led to a decrease in the preconcentration factor and to interfere with the back-extraction.

Generally, the volume of surfactant added to the sample solution in CPE was low due to the high viscosity of surfactant ( $\eta \sim 20$  cP) and low CMC for Triton X-114 (0.20–0.35 mM) (Sirimanne *et al.*, 1998).

However, the efficiency of extraction was strongly affected by the amount of surfactant used. Maximum extraction efficiency maintained when the ratio of volume of rich phase to that of aqueous phase ( $V_s/V_a$ ) is minimum leading to improve the preconcentration factor (Khammas and Mubdir, 2014).

#### 3.2.5. Effect of temperature and time

Cloud point extraction is a type of equilibrium extraction. The optimal extraction efficiency was obtained once the equilibrium temperature and incubation time were established. The two factors were studied in the range of 20.0–80.0 °C and 5.0–70.0 min, respectively, as shown in Figures 7 and 8.

According to the results (Figures 7 and 8), maximum absorption was achieved at a

temperature 50 °C, and at time 20 min for that, these two factors were recommended for the CPE procedure.

### 3.2.6. Effect of order addition

Several experiments have been tried for the purpose of testing the order of reactants addition. According to the highest absorption maintained number 1 was chosen for the CPE procedure. This can be explained due to the reduction of  $\text{Fe}^{+3}$  to  $\text{Fe}^{+2}$  ion by R-HCl, then reacted with ferricyanide to produce a Prussian blue color product. These experiments sorted in Table 1.

### 3.2.7. Calibration curve

Under optimization conditions, linearity was achieved at a concentration between (0.5–60.0)  $\mu\text{g/mL}$ . The calibration curve was maintained by plotting absorption versus concentrations of R-HCl at  $\lambda_{\text{max}} = 693 \text{ nm}$  (Figure 9). The analysis of data obtained from the calibration curve, as illustrated in Table 2.

## 3.3. Method Validation

### 3.3.1. Accuracy and precision

Accuracy and precision regarded as the most requirements for testing the method reliability and quality of the results obtained. For that accuracy was studied in term of percentage recovery by subjected three different concentrations within the calibration curve (5.0, 10.0 and 30.0  $\mu\text{g/mL}$ ) to CPE procedure. Precision also studied in terms of repeatability for five times. All results of accuracy and precision were illustrated in Table 3. The results indicated that the proposed method has a good precise, and small systematic error, which can be useful for analysis the of R-HCl in pharmaceutical preparations.

## 3.4. Application

Two products contain R-HCl (Reptidine 150 mg and Ranimac 150 mg) were chosen from a local pharmacy for application study. Ten tables of each product were weighted, grind and mix well to form bulky homogenous powders. Then 0.1 g of pure R-HCl from each product was dissolved in distilled water and complete the volume to the mark in 100 mL volumetric flask to prepare 1000

$\mu\text{g/mL}$ . From these two solutions 50  $\mu\text{g/mL}$  was prepared for the application study for the proposed method.

## 4. CONCLUSIONS

A newly developed method was preceded by a combination of cloud point extraction (CPE) and spectrophotometry to determine ranitidine-HCl in the pharmaceutical dosage form. This method could be a good alternative for the liquid-liquid extraction (LLE), method which consumes a large volume of solutions and also more useful than solid-phase extraction (SPE) due to the high cost of SPE columns.

The developed CPE–spectrophotometry method was economical, rapid, and simple, due to the analytical parameters obtained (percentage recovery of extraction, LOD, LOQ, and RSD%), it can be used for monitoring R-HCl in pharmaceutical preparations.

## 5. ACKNOWLEDGMENTS

The authors were very grateful for the support provided from the colleagues in the departments of Chemistry and biology – College of science.

**RESUMO**

2020

No processo de digestão anaeróbica, a alternância de substâncias líquidas e sólidas na composição do substrato faz com que as bactérias se adaptem às condições variáveis, o que reduz significativamente a emissão de biogás e a concentração de metano, bem como aumenta o tempo de presença do substrato no biorreator. A solução para esse problema ao usar a destruição de cavitação pode não apenas minimizar a heterogeneidade da temperatura, mas também resolver o problema da mesma carga na biocenose e na superfície de contato máxima das bactérias durante a digestão anaeróbica no biorreator. As pesquisas realizadas mostraram que a composição e quantidade de biogás não são constantes e dependem do tipo de substrato que está sendo processado e da tecnologia de produção de biogás. Para estabilizar a composição do biogás resultante e torná-lo em uma fonte de energia alternativa independente e de alta qualidade, é possível usar a destruição da membrana ou a moagem de matérias-primas orgânicas. O consumo de energia, o tempo de fermentação e a concentração de metano na produção final de biogás dependem do tratamento primário. No presente artigo, propõe-se um modelo matemático do processo de moagem, dispersão e homogeneização de resíduos de fazendas leiteiras e de engorda, que permite determinar e otimizar seus parâmetros operacionais, bem como promover a digestão anaeróbica eficaz do substrato no biorreator. Para determinar o modelo matemático do processo biotecnológico de processamento de matérias-primas com parâmetros teóricos ou experimentais conhecidos, foram utilizados os métodos numéricos, que são uma das poderosas ferramentas matemáticas para solucionar o problema. Os resultados dos parâmetros operacionais dos processos estudados foram obtidos no ambiente Mathcad e testados no pacote de software de controle e monitoramento automatizado SCADATraceMode 6.10.1.

**Palavras-chave:** usina de biogás, destruição de cavitação, regressão hiperbólica.

**ABSTRACT**

During anaerobic fermentation, the alternation of liquid and solid substances in the substrate makes the bacteria adapt to changing conditions, which significantly reduces the biogas yield, reduces the methane concentration in it, and increases the retention time of the substrate in the bioreactor. The solution to this problem when using cavitation destruction can not only minimize temperature nonuniformity but also solve the problem of the same load on the biocenosis and maximum contact surface of bacteria during anaerobic fermentation in the bioreactor. Studies have shown that the composition and quantity of biogas are not constant and depend on the type of substrate being processed and the biogas production technology. To stabilize the composition of the resulting biogas and bring it to a high-quality, independent alternative energy source, it is possible using membrane destruction or crushing of organic raw materials. The energy consumption, fermentation time, and methane concentration in the final biogas output depend on the primary treatment. This work proposes a

mathematical model of the process of crushing, dispersing, and blending waste from dairy and fattening farms, which allows to determine and optimize its operating parameters, as well as to promote effective anaerobic fermentation of the substrate in the bioreactor. To determine the mathematical model for the raw materials biological processing with known theoretical or experimental parameters, numerical methods were used, which are one of the powerful mathematical tools for solving the problem. The results of the operational parameters of the studied processes were obtained using the Mathcad environment and tested in the SCADA Trace Mode 6.10.1 automated process control and monitoring software package.

## АННОТАЦИЯ

В процессе анаэробного сбраживания чередование жидких и твердых веществ в составе субстрата заставляют бактерии приспосабливаться к меняющимся условиям, что значительно сокращает выход биогаза, снижают концентрацию метана в нем и увеличивает срок пребывания субстрата в биореакторе. Решение данной проблемы при применении кавитационной деструкции позволяет не только свести к минимуму температурную неоднородность, но и решить вопрос одинаковой нагрузки на биоценоз и максимальную поверхность контакта бактерий во время анаэробного сбраживания в биореакторе. Проведенные исследования показали, что состав и количество биогаза не являются постоянными и зависят от вида перерабатываемого субстрата и технологии производства биогаза. Для стабилизации состава получаемого биогаза и доведение его до качественного, самостоятельного альтернативного источника энергии возможно при использовании мембранной деструкции или измельчении органического сырья. От первичной обработки зависят энергозатраты, время брожения и концентрация метана в конечном выходе биогаза. В статье предложена математическая модель процесса измельчения, диспергации и гомогенизации отходов молочно-товарных и откормочных ферм, позволяющая определить и оптимизировать его режимные параметры, а также способствовать эффективному анаэробному сбраживанию субстрата в биореакторе. Для определения математической модели процесса биотехнологического процесса обработки сырья при известных теоретических или экспериментальных параметрах использовали численные методы, которые являются одним из мощных математических средств решения задачи. Результаты режимных параметров исследуемых процессов были получены с использованием среды Mathcad и протестированы в программном комплексе автоматизированного управления и контроля за технологическими процессами SCADATraceMode 6.10.1.

**Ключевые слова:** *биогазовая установка, кавитационная деструкция, гиперболическая регрессия.*

## 1. INTRODUCTION

There are works of domestic and foreign scientists, as well as specialists in the field of intensification of anaerobic fermentation of cattle excrement in biogas units, their degree of automation, and control: S. D. Durdybaev, Yu. N. Sidyganov, V. Baader, B. Eder, E.S. Pankshava, V. P. Druzianova, V. I. Marchenko, E. Hashimoto, A. G. Kudryashova, L. I. Ruzhinskaya, I. A. Trakhunova, E. K. Vachagina, V. A. Ivanov (Akhnazarova and Kafarov, 1985; Druzyanova, 2008; Eder and Schulz, 2011; Kudryashova, 2011; Ivanov and Gasparyan, 2013; Ruzhinskaya and Fomenkova, 2014; Tlebayev *et al.*, 2017; Butova *et al.*, 2018). These authors noted that during anaerobic fermentation, the alternation of liquid and solid substances in the substrate makes the bacteria adapt to changing conditions, which significantly reduces the biogas yield, reduces the methane concentration in it, and increases the retention time of the substrate in the bioreactor

(Biogas manual..., 2010; Dong *et al.*, 2018; Kusuma *et al.*, 2019).

In animal waste, there are various solid particles, such as sand, clay, *et al.*, which cause the formation of sediment, while light materials like straw and others rise to the surface of the bioreactor and form a crust, which leads to a decrease in gas formation (Koller *et al.*, 2017; Zagorulko *et al.*, 2018; Sokolova *et al.*, 2018; Isakov *et al.*, 2019; Kudrin *et al.*, 2019; Popov *et al.*, 2019). Therefore, plant residues (straw, scraps and others) must be crushed before loading into the reactor, and it is necessary to strive for the absence of solids in the raw materials (Sidyganov *et al.*, 2008; Golubtsova, 2017). To eliminate the problem, Figure 1 presents a developed primary treatment system for cavitation destruction of cattle excrement and anaerobic fermentation in a psychrophilic (are extremophilic organisms that are capable of growth and reproduction in low temperatures) mode (Dotsenko *et al.*, 2017; Kulbjakina and Dolotovskij, 2018; Chandra *et al.*,

2019).

The main goal of the raw materials processing unit mathematical modeling is to determine the optimal conditions for the process, to control it on the basis of a mathematical model, and transfer the results to a real object in the Birlik-Tuimekent SEC.

Liquid raw materials (cattle manure) 2 weighing 600 liters, humidity 80-85% enters tank 1, where it mixes with water at room temperature, in a ratio of 1:1, to a moisture content of 92%. From the tank 1, the raw material enters through the pipe 3, with the help of the pump 4, into the spiral separator 5, where large particles of the raw material are crushed. Next, the pre-crushed biomass enters the tank 6. Entering the macerator 9, solid particles are crushed, and heavy impurities are simultaneously separated. Further, the gerotor type pump 10 breaks the long fibrous inclusions present in the biomass, pumping the substrate into the dispersing agent 11, which exposes the composition of the substrate to destruction and creates a homogeneous mixture. While the biomass is in the tank 6, an automatic mixer 7 periodically mixes it. During crushing of the biomass in the tank 6, biogas enriched in CO<sub>2</sub> is released and removed through the pipe 13. When the required size of crushing is reached, the lower valve 12 is closed, and the upper valve 12 is opened, where the crushed substrate pumped into the bioreactor of the second stage of the biogas unit.

The biogas unit (BGU) effectiveness is greatly influenced by the preliminary preparation of the initial substrate. The smaller the particle sizes of the organic feedstock components, the greater their specific surface area and, accordingly, the fermentation processes occur more intensively. When analyzing literary sources, as articles by I. V. Meshcheryakov, "Development and research of a multistage hydro-percussion and cavitation device for fine crushing of complex ores" and A.T. Zhumagazhinov, N.K. Algazinov "Methods of intensification of the anaerobic fermentation processes" (Meshcheryakov, 2014; Kiss et al., 2015; Vachagina and Karaeva, 2009; Zhumagazhinov and Algazinov, 2014; Trakhunova, 2014), a table of the relationship between the destruction efficiency and performance was compiled (Table 1).

## 2. MATERIALS AND METHODS

To determine the mathematical model for the raw materials biological processing with known theoretical or experimental parameters, numerical

methods were used, which are one of the powerful mathematical tools for solving the problem.

To find the Equation 4, the approximation method was used in the work. Approximation allows us to study the numerical characteristics and qualitative properties of an object, reducing the problem to the study of simpler or more convenient objects (for example, characteristics of which are easily calculated or whose properties are already known).

To find the function in work, the approximation approach was used. At the initial stage, it was compiled a table of auxiliary quantities (Table 2).

To verify the found function was used, a computer experiment method implemented through the Scada Trace Mode automated process control and monitoring system. At the same time, to implement the full software package, all possible programming methods were used—namely, the creation of modules in different programming languages of the International Electrotechnical Commission 6-1131/3 standard. Firstly, as the fundamental programming languages of this standard, the Tehno Structured Text (a high-level programming language similar to Pascal) and the Tehno Instruction List (the simplest mnemonic instruction language that looks like assembly), as well as the Tehno Function Block Diagram visual languages (is a diagram consisting of a set of functional blocks interconnected via inputs and outputs), Techno Sequential Function Chart (a tool for structuring complex algorithms), Techno Ladder Diagram (ladder logic diagrams).

## 3. RESULTS AND DISCUSSION:

In domestic and foreign practices are increasingly being used energy supply systems for agricultural enterprises using an alternative energy source - biogas. Biogas is formed as a result of anaerobic fermentation of organic substances when waste is processed, and highly effective biofertilizers are obtained. It also solves the environmental and agrobiological problems of agricultural enterprises. For the production of biogas, bioreactors are widely used. In most countries of the world, biogas technologies have become the standard for the processing of biowaste in order to obtain additional raw materials and energy resources. The need to increase the energy efficiency of a biogas plant is due to the large energy consumption for the technological needs of the equipment. According to the classification presented in the article, the main

instruments in the technological scheme of the processing of organic raw materials are a mixing tank, a macerator, a gerotor pump, a cavitation destructor, which largely determines the effectiveness of the technology as a whole. A promising measure to increase the energy efficiency of methane fermentation technology is the availability of primary processing of raw materials.

The data from Table 1 point that after the 6th cycle, the values of the change in the size of the initial particles are minimal, less than 10 microns; it was considered the 6th cycle to be inappropriate.

It was calculated the a and b coefficients for the hyperbolic regression equation (Equation 1). According to the well-known equations (Equations 2-3) (Akhnazarova and Kafarov, 1985). In sum, the desired regression equation has the form (Equation 4). Where x is the number of passes, and y is the particle size of the crushed mixture after the x-th pass.

Let's analyze the graph of the regression equation using the Mathcad program (Figure 2). In this connection, the index of correlation (Equation 5). And the determination index:  $R^2 = 0.9725^2 \approx 0.9457$ . Analyzing the graph, it could be concluded that equation (4) describes the crushing process only up to  $x \leq 4$  or before crushing at 14 microns. With large crushing, the error of approximation increases, and the data becomes incorrect.

To find the function that describes the crushing process after about 14 microns, the Trendline function in Excel was used (Figure 3). The average error of approximation (Equation 6). Moreover, the average approximation error is 17.89%, which indicates a good "fit" of the obtained function to the parameters under study. It was simulated this function in Mathcad (Figure 4).

Further, the organic raw materials processing (crushing) can be described by the system of equations (Equation 7). This equation describes the grinding process, where x is the number of passes of the processing of organic raw materials, f(x) is the size of the particles of the crushed mixture after the x pass, while the first equation is applicable for large grinding, and the second describes the grinding process after about 14 microns.

Find the intersection point of the graphs to determine the conditions of the system (Figure 5). Figure 5 shows that the graphs intersect at  $x =$

3.7282,  $y = 18.184$ . Rounding off the values to integers, a system of equations with limitations was obtained (Equation 8).

To display the general equation of the processing of the raw materials through the preferred parameters (processing time and loading volume), the equation for the processing time was derived, so the number of cycles necessary to complete in one pass is defined as (Equation 9). Where  $V_{vol}$  is the volume of loaded raw material (l), the parameter  $V_{pip}$  is the total volume of the system pipes ( $V_{vol}=4.69$ ).

Processing time in one pass is calculated as (Equation 10). Where  $T_u$  is the total execution time of one cycle ( $T_{cycl}=9.61$ ). Further, the total runtime of the processing of the raw materials can be represented in the form (Equations 11-12).

Using the static parameters of the system was obtained (Equations 13-14). It was substituted the obtained value of X into the system of equations, general expression (Equation 15). For a given system (Equation 16), having simplified was obtained (Equation 17).

The time required to crush a given value (micron) can be calculated by a function in a general form (Equation 18). For a given system for organic raw materials processing (Equation 19), where V is the volume of the loaded raw material (l), L is the desired output size (microns),  $T_{o6}$  which is the required time to complete the process (sec).

For finer crushing, you should use the second function of the system, in general, the function of finding the processing time will have a form (Equation 20). Where:  $V_{vol}$  is the volume of loaded raw material (l);  $T_{cycl}$  – the total execution time of one cycle ( $T_u=9.61$ ); L is the desired output size (microns);  $V_{pip}$  – the volume of the pipe system;  $T_{o6}$  – the required time to complete the process (sec).

Substituting the parameter values was obtained (Equation 21). Thus, the system of equations for finding the processing time in a general form can be represented as (Equation 22) for the studied processing system as (Equation 23). It was constructed the resulting system of equations in Mathcad (Figure 6).

The increase in the degree of decomposition is proportional to the increase in the active surface of the organic substance involved in the process of methane formation and has a substantially nonlinear character, which

makes it possible to use this effect to intensify gas escape in biogas technologies.

The use of cavitation destructors can significantly reduce the time of raw materials pretreatment, due to the effect of the destruction of the membrane of raw materials particles. Cavitation destructor allows us to use the destructive effect of cavitation to give the feedstock a homogeneous mass. Under the influence of directed and controlled cavitation in the biological raw materials, complex bonds of the fibers of organic substances at the molecular level (lignin, cellulose) are breaking. As a consequence of this process, the dispersion of biological raw materials is significantly increased, and its particles are reduced in size to 0.1 - 8 microns. Thus, it becomes easier for all bacterial strains involved in the biogas formation at all its stages to decompose biogenic materials, because their homogeneous structure is destroyed and, accordingly, the area covered by bacteria of biological raw materials increases. (Obolensky and Kravynov, 2012). All these factors contribute to improving energy efficiency and reducing equipment wearing.

Of course, even the most complex models are not yet able to describe all the existing relationships, reflect the whole variety of behavior of complex agrobiological systems in various situations. However, the obtained equations are able to describe the process of crushing dispersion and homogenization of the substrate for an optimal control system, the regime of periodic loading of a new portion of raw materials, and the temperature regime of the fermentation in the capacity of the psychrophilic regime, while saving energy (Yudaev *et al.*, 2019; Barisa *et al.*, 2020).

To analyze the resulting mathematical model, a computer experiment was conducted in the Scada Trace Mode. Trace Mode consists of an instrumental system and a set of executive modules (runtimes). Using the Trace Mode executive modules, the project of the automated control system is launched for execution in real-time at the workplace by dispatcher or operator. If we need to organize communication between Trace Mode and Arduino, we can use the modbus-rtu protocol and connect the converter to RS – 485 or RS-232.

An automated system for controlling the technological processes of organic raw material recycling is a form divided into four logical zones (Figure 7):

1. A graphical representation of the raw materials processing unit structural elements.

2. Parameters and schedule for raw materials crushing.

3. Calculation of indicators for heating raw materials at a psychrophilic mode.

4. Calculation of the CO<sub>2</sub> concentration at the outlet.

As a reference plan for the experiment, a matrix of initial and final parameter values will be created (Zhumagazhinov and Algazinov, 2014). To identify the relationship between the particle size at the outlet and the concentration of biogas, it was assumed that (Table 3):

- the volume of loaded raw materials;
- the volume of the pipes of the raw materials processing unit;
- the initial temperature of raw materials;
- the desired temperature of the raw material, there are constant values, and only the desired particle size at the outlet changes.

Thus, when entering the initial parameters, the system calculates the outlet parameters (Figure 8). Similarly, all other experiments will be conducted. After conducting the experiments, the data obtained was analyzed (Table 4).

As can be seen from the graph (Figure 9), with a decrease in particles, methane yield (CH<sub>4</sub>) increases, and the percentage of carbon dioxide (CO<sub>2</sub>) decreases. However, it can be seen that after particle crushing by less than 10 microns, the methane increase is insignificant, but the processing time of the raw materials increases and, consequently, the financial costs and equipment wear increase (Figure 10).

Thus, particles of a fraction of 10 µm will be the main ones for biogas production and will have a high level of flotation; smaller particles make a small contribution to the formation of methane and are prone to precipitation. This confirms the previously obtained assumption, based on the values of Table 1, about the inappropriateness of processing raw materials of more than 10 microns.

In a production environment, in addition to the main set of factors studied using a computer experiment, process indicators are influenced by many factors that are difficult or impossible to control. This leads to the fact that the optimal conditions found through a computer experiment are often not reproduced in industry. In this regard, it is necessary to periodically conduct an experiment directly at an industrial facility to refine and control the initial parameters.

The mathematical modeling of the process of animal waste crushing using cavitation destruction consists of three interrelated stages:

- compilation of a mathematical description of the raw materials processing unit;

- the choice of a solution method of the system of equations of mathematical description and its implementation in the form of a modeling program;

- establishing conformity (adequacy) of the raw materials processing unit model of pilot industrial biogas technology at the facility in the Birlik – Tuimekent SEC;

- at the stage of compiling the mathematical description, the main factors and parameters in the raw materials processing unit are identified, and then the relationships between them are established. Further, for each selected parameter and factor, a system of equations reflecting its functioning and the equations of connection between them was wrote;

- at the stage of choosing a solution method and developing a modeling program. The system of nonlinear equations was solved in the Mathcad environment, which was distinguished by the speed of obtaining and accuracy of the solution and its implementation first in the form of a solution algorithm, and then in the form of a program suitable for computer calculation;

- at the stage of testing the mathematical model, a computer experiment was conducted in the TRACE MODE tool system;

- the raw materials processing unit model built on the basis of physical concepts qualitatively and quantitatively describes the properties of the simulated process and is adequate to the real object in the Birlik – Tuimekent SEC;

- at the stage of checking the adequacy of the mathematical model for the real process, the results of measurements at the Birlik – Tuimekent SEC were compared with the calculation results obtained from the mathematical model and mathematical modeling.

In this article:

1. The physical and chemical foundations of the process of biogas production during anaerobic solid waste fermentation were considered;

2. The component parts of the organic raw materials processing unit were examined;

3. Literary sources were analyzed using numerical methods of data processing, and a

mathematical model was obtained for the process of organic raw materials primary procession.

4. A visual model of the biomass grinding process was built;

5. The parameters of heating the substrate to the parameters of the psychrophilic temperature regime were considered;

6. The equation for determining the percentage of biogas concentration was calculated;

7. The optimal time of biomass processing to the required size was calculated with the modified parameters of the modernized system;

8. An automated process control system was developed based on the received data;

9. A computer experiment was conducted to identify the optimal working parameters of the biogas plant.

#### 4. CONCLUSIONS:

The greening of all production processes today is quite relevant. Therefore, in the article, a computer-assisted mathematical model for the raw materials biological processing was created. To analyse the resulting mathematical model, a computer experiment was conducted in the Scada Trace Mode system.

It was established that particles of the 10  $\mu\text{m}$  fraction will be key for biogas production, since they have a high level of flotation, smaller particles make a small contribution to the formation of methane and are prone to precipitation.

It has been demonstrated that the use of cavitation destruction can significantly reduce the volume of natural organic raw materials and destroy intercellular membranes, thereby use plant fibers most efficiently, significantly increase the speed and depth of extraction of raw materials, as well as its subsequent period of fermentation. And the use of modern automation systems for production processes, such as ScadaTraceMode and others, allows us to save time and technological resources, to avoid equipment deterioration during the experiment.

**RESUMO**

A relevância do artigo deve-se ao crescimento estável da indústria de compósitos. Devido às suas altas características físicas e mecânicas, os materiais compósitos (MC) desempenham um papel vital em muitas áreas da tecnologia, como indústria aeroespacial, aviação, indústria automotiva, engenharia e instrumentação e a indústria médica. Ao criar os materiais com as características mecânicas e térmicas necessárias, são frequentemente usados vários aditivos e enchimentos que afetam a resistência e a elasticidade das amostras obtidas. Neste artigo, estudamos o efeito de inclusões esféricas em resina epóxi nas propriedades mecânicas do material. Uma estrutura composta de resina epóxi ED-20 com inclusões na forma de partículas esféricas de vidro PBS-50 foi considerada. O tamanho característico das partículas foi de cerca de 50 µm. No âmbito deste estudo, foram produzidos lotes de amostras com o volume característico de inclusões de 5%, 10%, 15% e 20%. Cada lote consistia em 6 amostras do mesmo tipo. Para verificar a distribuição do volume de partículas e estudar as inclusões, a microestrutura da seção delgada da amostra e o pó foram estudadas separadamente. Usando métodos de modelagem do processo, as amostras foram submetidas ao teste de flexão de três pontos. Com base nos resultados de testes mecânicos, foram obtidos o módulo de elasticidade, a resistência à tração e as deformações finais. Como parte do estudo dos materiais, foram realizados os cálculos numéricos usando o software Digimat (MSC Software) para modelar a estrutura e obter propriedades efetivas do material. Também foram realizados os cálculos de tensões usando o método dos elementos finitos em Ansys Workbench. O cálculo foi realizado para o conteúdo volumétrico de inclusões da ordem de 5%, 10%, 15% e 20% e na ausência de inclusões. Os resultados numéricos obtidos foram comparados com o estudo experimental. Com base nos cálculos numéricos, foi obtida a dependência da porcentagem de inclusões na resistência à tração e no módulo de elasticidade.

**ABSTRACT**

The relevance of the article is due to the stable growth of the composite industry. Due to its high physical and mechanical characteristics, composite materials (CM) play a vital role in many areas of technology, such as aerospace, aviation, automotive, engineering and instrumentation, and the medical industry. When creating materials with the required mechanical and thermal characteristics, various additives and fillers are often used that affect the strength and elasticity of the samples obtained. In this paper, we study the influence of spherical inclusions in epoxy on the mechanical properties of the material. A composite structure of ED-20 epoxy with

inclusions in the form of spherical particles of PBS-50 glass was considered. The characteristic particle size was about 50  $\mu\text{m}$ . Within the framework of this study, batches of samples with a specific volumetric inclusion content of 5%, 10%, 15%, and 20% were produced. Each batch consisted of 6 samples of the same type. To check the distribution of particle volume and inclusion studies, the microstructure of the thin section of the sample and separately the powder were studied. Using methods of modeling the process, the samples were tested for 3-point bending. Based on the results of mechanical tests, the elastic module, strength limit, and ultimate strains were obtained. As part of the study of materials, numerical calculations were performed using Digimat software (MSC Software) to model the structure and obtain effective material properties, as well as strength analysis using the finite element method in Ansys Workbench. The calculation was carried out for the volumetric content of inclusions of 5%, 10%, 15%, and 20% order and in the absence of inclusions. The obtained numerical results were compared with an experimental study. Based on the numerical calculations, the dependence of the percentage of inclusions on the strength limit and elastic module was obtained.

## АННОТАЦИЯ

Актуальность статьи обусловлена стабильным ростом композитной промышленности. Благодаря высоким физико-механическим характеристикам, композитные материалы (КМ) играют жизненно важную роль во многих областях техники, таких как аэрокосмическая, авиационная техника, автомобильная промышленность, машиностроение и приборостроение, медицинская отрасли. При создании материалов с требуемыми механическими и тепловыми характеристиками часто используются различные добавки и наполнители, влияющие на прочность и упругость полученных образцов. В данной работе исследуется влияние сферических включений в эпоксидной смоле на механические свойства материала. Рассматривалась композитная структура из эпоксидной смолы ЭД-20 с добавленными в нее включениями в виде сферических частиц стекла ПБС-50. Характерный размер частиц составлял порядка 50 мкм. В рамках данного исследования изготавливались партии образцов с характерным объемным содержанием включений равным 5%, 10%, 15% и 20%. Каждая партия состояла из 6 однотипных образцов. Для проверки распределения частиц по объему и исследования включения проводились исследования микроструктуры шлифа образца и отдельно порошка. Используя методы моделирования процесса, образцы испытывались на 3х точечный изгиб. По результатам механических испытаний были получены модуль упругости, предел прочности и предельные деформации. В рамках исследования материалов проводились численные расчеты с использованием программного обеспечения Digimat (MSC Software) для моделирования структуры и получения эффективных свойств материала, а также, проводился прочностной расчет с использованием метода конечных элементов в среде Ansys Workbench. Расчет проводился для объемного содержания включений порядка 5%, 10%, 15% и 20% и при отсутствии включений. Полученные численные результаты сравнивались с экспериментальным исследованием. На основании проведенных численных расчетов была получена зависимость процентного содержания включений от предела прочности и модуля упругости.

**Ключевые слова:** *композиционный материал, сферическое включение, испытание на изгиб, объемная доля, механические свойства.*

## 1. INTRODUCTION

The production and use of composite materials (CM) is growing steadily every year. Currently, CMs play a vital role in many areas of technology, such as aerospace, aeronautical engineering, automotive industry, mechanical engineering, and instrumentation, the medical industry and more (Yushkova *et al.*, 2010; Dmitriev *et al.*, 2011; Shershak, 2019; Yu Timkina *et al.*, 2019). The reasons for this rapid growth of the composite industry are low density of products, high physical and mechanical characteristics, resistance to corrosion and aggressive environments, as well as the ability to create

materials with the required mechanical and thermal characteristics (Lakes *et al.*, 2002; Orlov *et al.*, 2001; Jae-soon, 2012). One of the options for obtaining the necessary properties of materials is the use of various additives, for example, the addition of inclusions in the polymer matrix (Trofimov *et al.*, 2017; Wang *et al.*, 2019; Prentkovskis *et al.*, 2012).

The matrix (binding agent) is the most important element of the composite and determines the nature of the change in its properties when exposed to various factors (temperature, chemical resistance, electrical and other properties). A deeper understanding of the

interaction of inclusions and matrix, as well as the influence of the volumetric content of the included particles on the physical and mechanical characteristics, has emerged with the development of nanotechnologies. That is why the study of the mechanical characteristics of CM samples with various fillers and additives is an extremely urgent task (Tagliavia *et al.*, 2010; Tkachev *et al.*, 2018; Xinfeng *et al.*, 2018; Umbetov *et al.*, 2016). At the moment, there are many studies describing the use of inclusions to improve the physical and mechanical characteristics of composites (Odegard *et al.*, 2005; Sanchez-Soto *et al.*, 2007; Vettegren *et al.*, 2007; Song, 2009; Hurang *et al.*, 2010; Markus *et al.*, 2013; Seighalani *et al.*, 2015; Babaytsev *et al.*, 2017; Kenzhaev, 2019; Ryapukhin *et al.*, 2019; Formalev *et al.*, 2019; Jeyaprakash and Devaraju, 2020). However, the addition of particles is nonlinear and depends on many factors, such as the structure of the material from which the inclusions are made, the shape and size of the particles, as well as the volume fraction of inclusions (Markus *et al.*, 2013; Hnatiuk *et al.*, 2019; Jeyaprakash and Devaraju, 2019).

The aim of this work is to prepare and study the mechanical characteristics of glass dispersed and epoxy-filled composites. In this work, we consider the composite structure of the ED-20 epoxy, into which glass particles with a characteristic size of about 50  $\mu\text{m}$  are added. In this paper, five different batches of samples are presented, depending on the volume fraction of inclusions. Each batch consisted of 6 samples of the same type. To check the distribution of particle volume and inclusion studies, the microstructure of the thin section of the sample and separately the powder was studied. Moreover, to study the influence of inclusions (spheres) on the mechanical characteristics of CMs, tests were carried out on samples with three-point bending. As part of the study, a numerical calculation was performed using Digimat MSC Software and Ansys Workbench (Odegard *et al.*, 2005; Lakes *et al.*, 2002; Hurang *et al.*, 2010; Yushkova *et al.*, 2010; Jae-soon, 2012; Xinfeng *et al.*, 2018; Shershak, 2019).

## 2. MATERIALS AND METHODS

In the study, samples of epoxy with inclusions and pure epoxy were studied. An ED-20 epoxy was used as a matrix, and PBS-50 glass spheres with a characteristic sphere size of about 50  $\mu\text{m}$  were used as inclusions. The volumetric content of inclusions was 5%, 10%, 15% and 20%. The material for the samples in this study was

epoxy composites filled with spherical glass particles with a characteristic size of about 50  $\mu\text{m}$ . The particle-filled polymer composites used in the experiments are batches of samples consisting of five types of volume fraction of the filler: 0%, 5%, 10%, 15%, and 20%. A diagram of the process of manufacturing samples is given in Figure 1. In the framework of this study, samples with a rectangular cross-section of 10 mm x 4 mm and a length of 80 mm were used. Quality control – visual inspection, mixing lasted for 25 minutes, vacuum with degassing was used, cooling took place within 3 hours.

To do this, a plate was made, and then samples were cut from it. For each batch of samples, six samples of the same type were produced. Photos of the studied samples are presented in Figure 2. To check the distribution of inclusions by volume, their percentage, as well as confirm the size of the inclusions, we studied the microstructure of the thin section of the sample and separately the powder. The results of microscopy are presented in Figure 3.

To determine the effect of inclusions on the mechanical characteristics of CM, bend tests were performed. The tests were carried out according to standard test procedures on an Instron 5969 universal testing machine with Bluehill software. For each tested batch, a stress-strain curve was constructed (Figure 4). As can be seen from the test results, the presence of inclusion significantly affects the CM mechanical characteristics.

## 3. RESULTS AND DISCUSSION:

For a more detailed study of the structure under study, a numerical calculation was performed. For this purpose, using the Digimat MF software, a structure with the exact use of matrix and inclusion properties, as well as the distribution of inclusions by volume, were preliminarily modeled. All materials were considered as isotropic linearly elastic materials for spherical inclusion and an epoxy polymer matrix and were presented in Table 1.

For each variant of the volumetric content of inclusions, a calculation and determination of the stress-strain curve of the structure under study were carried out. A representative elementary volume with a volume fraction of inclusions is shown in Figure 5. In a representative fragment, it was assumed that the contact between the particles and the matrix is perfect, there is no slip. The result obtained in the process of this calculation for each case under consideration is presented in Figure 6.

After obtaining the characteristics of the CM, a sample was created similar to the experimental sample in ANSYS Workbench. A three-point bending test process was simulated, where the boundary conditions for a rectangular plate were taken from the condition of free bearing on supports. Of course, the elemental model consisted of 16.469 nodes and 3.200 elements, with an element size of ~ 1 mm (Figure 7a). An example of a strain-stress state of the epoxy plate without inclusion is shown in the figure (Figure 7b).

Thus, based on the numerical calculations, the dependence of the percentage of inclusions on the strength limit and elastic module was obtained. The numerical results obtained are in good agreement with experimental results, which makes it possible to select such a volumetric content of inclusions in order to obtain the necessary physical and mechanical characteristics of the CM. However, in such CMs with a sufficiently large number of inclusions, these particles become stress concentrates and significantly reduce the strength limit and ultimate strains.

The tests performed showed a significant effect of the presence of inclusions of more than 15% on the strength limit and ultimate strain. As part of this study, a numerical analysis of the tested structure was performed using Digimat and Ansys. The results of numerical simulation are in good agreement with the experimental results until the inclusion is equal to 10%. In addition, with an increase in the volumetric content of inclusions, the divergence of the numerical and experimental results begins. This is most likely due to the condition of contact between the inclusions and the matrix and with possible internal defects.

#### 4. CONCLUSIONS:

The mechanical characteristics of glass dispersed and epoxy-filled composites, samples with various inclusions were manufactured. Microscopy and mechanical testing of samples were carried out. Structural studies confirmed the size of the inclusions and their distribution over the sample volume. Based on the results of mechanical tests, the elastic module, strength limit, and ultimate strains were obtained. The tests performed showed a significant influence of the presence of inclusions of more than 15% on the strength limit and ultimate strain. The results of numerical modeling are in good agreement with the experimental results, and with an increase in the volumetric content of inclusions, the divergence of the numerical and experimental

results begins. This is due to the condition of contact between the inclusions and the matrix and with possible internal defects, and therefore requires additional research and more accurate modeling.

#### 5. ACKNOWLEDGMENTS:

The work was carried out with the financial support of the state project of the Ministry of Education and Science on the subject "Theoretical and experimental research in the field of production and processing of promising metal and composite materials based on aluminum and titanium alloys", project code FSFF-2020-0017.

**RESUMO**

Um dos métodos químicos de impacto no reservatório para melhorar a eficiência do processo de desenvolvimento de campos de petróleo é inundação de polímeros. Este artigo descreve um estudo de viabilidade da eficácia da aplicação da tecnologia de inundação de polímeros no campo no Cazaquistão Ocidental. Este campo é caracterizado por alta viscosidade do óleo do reservatório, corte de água e heterogeneidade dinâmica do reservatório. A experiência mundial na aplicação de inundações de polímeros em campos análogos mostra alta eficiência tecnológica. São apresentados os resultados da análise da experiência da aplicação da tecnologia em campos análogos, estudos físico-químicos de polímeros, estudos de filtração em tubos cheios de areia, modelagem hidrodinâmica de inundações de polímeros e a relação custo-benefício esperada da introdução da tecnologia, aplicada às condições do campo de Karazhanbas com alta viscosidade do óleo de reservatório. A análise baseada na experiência de aplicação de inundações de polímeros em campos de petróleo de alta viscosidade, estudos de laboratório e cálculos estimados da produção esperada no modelo geológico e hidrodinâmico do setor mostra a diminuição no corte de água, o aumento na produção de petróleo e na recuperação atual e final de óleo.

**ABSTRACT**

One of the chemical methods of stimulating the reservoir to increase the efficiency of the oil field development process is polymer flooding. This article conducted a feasibility study of the effectiveness of the application of polymer flooding technology in one field in Western Kazakhstan. This field is characterized by high viscosity of reservoir oil, water cut, and dynamic heterogeneity of the reservoir. World experience in the application of polymer flooding in analogous fields shows high technological efficiency. Presented results of the analysis of the experience of applying technology in analogous fields, physicochemical studies of polymers, filtration studies on bulk models, hydrodynamic modeling of polymer flooding and the expected cost-effectiveness of introducing the technology, as applied to the conditions of the Karazhanbas oil field with high viscosity of reservoir oil. The analysis based on the experience of applying polymer flooding in high-viscosity oil fields, laboratory studies and estimated calculations of the expected production in the sector geological and hydrodynamic model shows a decrease in water cut, an increase in oil production, and an increase in current and final oil recovery.

**Keywords:** *filtration studies, hydrodynamic modeling, technical and economic efficiency, polymer flooding (PF), field trial (FT).*

## АННОТАЦИЯ

Одним из химических методов воздействия на пласт для повышения эффективности процесса разработки нефтяных месторождений является полимерное заводнение пластов. В данной статье проведено технико-экономическая оценка эффективности применения технологии полимерного заводнения на одной месторождения Западного Казахстана. Данное месторождение характеризуется высокой вязкостью пластовой нефти, обводненностью и динамической неоднородностью пласта. Мировой опыт применения полимерного заводнения на месторождениях аналогах показывает высокую технологическую эффективность. Приведены результаты анализа опыта применения технологии на месторождениях аналогах, физико-химических исследований полимеров, фильтрационных исследований на насыпных моделях, гидродинамического моделирования процесса полимерного заводнения и ожидаемой экономической эффективности внедрения технологии, применительно к условиям месторождения Каражанбас с высокой вязкостью пластовой нефти. Проведенный анализ на основе опыта применения полимерного заводнения на месторождениях высоковязкой нефти, проведенных лабораторных исследований, оценочных расчетов ожидаемой добычи на секторной геолого-гидродинамической модели, показывает снижение обводненности, увеличение добычи нефти, прироста текущей и конечной нефтеотдачи.

**Ключевые слова:** *фильтрационные исследования, гидродинамическое моделирование, технико-экономическая эффективность, полимерное заводнение (ПЗ), опытно-промысловое испытание (ОПИ).*

## 1. INTRODUCTION

Traditional methods for increasing oil recovery in high-viscosity and heavy oil fields are aimed at reducing its viscosity and increasing mobility by injecting the heat into the reservoir. In some cases, thermal methods do not give a good result, for example, for thin-layered or deep-seated formations. Currently, the chemical methods of stimulation are the most commonly used to increase the efficiency of oil field development.

It was previously believed that polymer flooding was limited to use only in fields with light oil or with medium viscous oil, and thermal oil recovery methods were strictly applied in fields characterized by high viscosity oil (Babaytsev *et al.*, 2017; Kuznetsova and Rabinskiy, 2019; Formalev *et al.*, 2017; Gendler *et al.*, 2019). However, recently in world practice, this provision is no longer observed in connection with the successful use of polymer flooding for high-viscosity oil, where thermal methods do not seem feasible (Radyuk *et al.*, 2019; Samarin *et al.*, 2019). With the accumulation of new knowledge about the process, the development of new polymer compositions, and the reassessment of the rationality of polymer flooding parameters, this technology becomes economically viable when oil is extracted from reservoirs with a viscosity exceeding 100 mPa·s (Buzinov and Umrikhin,

1984).

This article presents the results of an analysis of the experience of applying technology in analogous fields, physicochemical studies of polymers, filtration studies on bulk models, hydrodynamic modeling of polymer flooding and the expected cost-effectiveness of introducing the technology, as applied to the conditions of the Karazhanbas field with high viscosity of reservoir oil. The results of experimental studies and hydrodynamic modeling of the polymer flooding process shows high technical and economic efficiency and gives the basis for field trial (Delamaide *et al.*, 2015; Orlov *et al.*, 2001; Lazarenko *et al.*, 2019; Formalev *et al.*, 2019; Bulychev, 2019; Sultanbekov *et al.*, 2020).

The experience of using analogs at deposits, to compare the results of the technology implementation at analogs deposits, the main technological parameters were summarized in Table 1 (Moe Soe Let *et al.*, 2012; Delamaide *et al.*, 2013). In this article, according to the author, we present the most striking example of the application of polymer flooding technology in a field with high viscosity of reservoir oil. The Pelican Lake field is similar to the Karazhanbas field in geological and physical parameters and is located 250 km north of Edmonton, Alberta, Canada. Development began in 1980. The field covers an area of 177.000 hectares and is part of the significantly larger "Wabasca" oil field. Geological

reserves are estimated at 6.4 billion barrels, and oil recovery factor is in the range of 5-10% (Delamaide *et al.*, 2013).

The dissolved gas is used as the development mode. However, the initial reservoir pressure is low, and very little dissolved gas is contained in the oil. Also, due to the high viscosity of the oil, the first vertical wells drilled in 1980-1981 were unprofitable with a flow rate below 30 barrels per day, characterized by an intensive drop to 10 barrels per day. The use of thermal methods could not improve oil recovery due to heat loss in such small thickness deposits. The introduction of horizontal well drilling yielded slightly better results in oil production by increasing coverage over the area.

## 2. MATERIALS AND METHODS

Despite the high oil viscosity, the conditions and characteristics of the field were ideal for polymer flooding: low formation temperatures, low water salinity, lack of active water (aquifer), and high permeability values (Wei *et al.*, 2007; Manichand *et al.*, 2010; Xiaodong and Jian, 2013). The first polymer flooding test was launched in 1996 in a cell with one injection well and two responsive production wells. This FT was unsuccessful due to the failure to achieve the planned viscosity (100-200 mPa\*s) (Akulshin, 2000). In addition, aquifer water in this area contained a large amount of  $\text{Fe}^{2+}$ . In this regard, preliminary aeration of the solution was started with the aim of changing  $\text{Fe}^{2+}$  in  $\text{Fe}(\text{OH})_3$ . Despite this, the injection decreased significantly due to the clogging of the incorrectly installed filter by iron particles, and the FT was stopped due to a change of management and incorrect conduct of the FT (Azga and Settari, 1982; Orlov *et al.*, 2003; Wassmuth *et al.*, 2007; Delamaide, 2014; Sheng *et al.*, 2015; Sultanbekov and Nazarova, 2019).

The second FT was launched in May 2005 with a planned initial solution viscosity of 20 mPa\*s, followed by a decrease to 13 mPa\*s. After analyzing the results of the first FT and laboratory studies, it was found that there is no need for high values of the viscosity of the polymer solution to improve the mobility coefficient. In order to avoid colmatization, it was also decided to reduce the molecular weight of the polymer to  $12.5 \times 10^6$  Daltons. A cell of 5 horizontal wells with a horizontal stem of 1.400 m and a borehole distance of 175 m was selected as the FT site. The response of production wells to injection was observed in February, April, and September 2006 for each of the three wells. In the first well, oil

production increased from 18 bbl/day to 232 bbl/day, from 9 bbl/day to 364 bbl/day in the central well, and from 16 bbl/day to 139 bbl/day in the last well (Figure 1).

The main indicator of the success of applying the PF is the relatively low rate of water cut growth for all three wells compared to the adjacent plot of water flow with normal flooding (Figure 2) (Amelin *et al.*, 1978; Amelin and Subbotina, 1986; Barashkin and Samarin, 2005). The cumulative injection is 0.3 d. pore volume (PV), the final predicted oil recovery factor reaches 25%. Based on the results of the successful conduct of the FT, it was decided to expand the impact area and start the PF in new areas.

A FT was also conducted at Pelican Lake to determine the effectiveness of the PF from the very beginning of development instead of the usual waterflooding and the regime of dissolved gas and to determine the variability of the effect of the PF with even more highly viscous oil. According to the results, it was found that the efficiency of oil production and improved oil recovery as a whole increase. The use of oil and gas at the present time indicates that the efficiency becomes lower compared to an increase in the viscosity of the oil, but nevertheless, the oil recovery becomes higher compared to a traditional refinery.

Based on the results of the successful conduct of several field trials at the Pelican Lake field, the effectiveness of PF was also proven for oil with a viscosity of up to 10,000 cPs. However, the effectiveness of PF in areas with an oil viscosity from 1000 cPs to 2000 cPs remains better and is characterized by a low rate of increase in water cut (Bagrintseva, 1982; Amelin *et al.*, 1991; Amelin *et al.*, 1994). With increasing viscosity, this effect decreases, but in the end, a significant increase in oil recovery is still achieved. In the case when the PF is used as the primary method of oil recovery from the very beginning of development, the effectiveness of the PF reaches its maximum value and is accompanied by a long and stable selection of oil.

To align the injectivity profile and regulate the waterflooding process, was used a technology with polymer systems based on a water-soluble AN-132 brand of acrylamide. Area of use, collector type is terrigenous – porous. Productive zone of the well occurring in the chalk deposits. They are represented by sandstones and argillaceous sandstones, characterized by alternating formations with medium and high porosity and permeability. The artificial bottom hole is 1330 m,

the current bottom hole is 1291.5 m. The accumulated injection is 4 056 344 m<sup>3</sup> of water.

### 3. RESULTS AND DISCUSSION:

#### 3.1. Site-Specific Conditions of the Karazhanbas Deposit

The effectiveness of polymer flooding technology is largely determined by the properties of the reagents used. The selection of reagents should be carried out, taking into account the individual characteristics and development status of a particular field (Balakin *et al.*, 1998). Associative polymers are one of the promising types of polymers for highly viscous deposits. These polymers have in their structure hydrophilic and hydrophobic units of macromolecules and consist of a long hydrophilic chain with a small number of hydrophobic groups located along with the main chain or at its ends (Barenblatt *et al.*, 1984; Barenblatt *et al.*, 1992).

Associative polymers have a high thickening ability in waters of various salinity, and this fact is an advantage of associative polymers over hydrolyzed polyacrylamides. Another advantage of associative polymers is their higher resistance to mechanical degradation due to the more rigid structure of macromolecules (Figure 3).

The authors propose to test the technology of polymer flooding with a combination of straightening of the injectivity profile deep in the reservoir. To do this, you need to choose two types of polymer, one for displacement (PF), the other conformance control (CC). When selecting a polymer for the conditions of a particular field, one should take into account: physico-chemical properties of produced and injected water; reservoir temperature; permeability and porosity of the formation; pore size; reservoir heterogeneity; mineralogical composition of reservoir rocks (Barenblatt *et al.*, 1960; Buzinov and Umrikhin, 1984; Bourdais and Algoa, 1984; Bourdais *et al.*, 1984; Basniev *et al.*, 1993).

For flooding at the Karazhanbas field, its own produced water is used (Table 2), the studied water according to the Sulin type is referred to as calcium chloride, with a total salinity of 26 g/l (at a density of 1.018 g/cm<sup>3</sup>), with a predominant content of chloride ions (15.7 g/l), pH of water at the neutral level – 7.1 units. The reservoir temperature of the Karazhanbas deposit in the zones of water injection does not exceed 30°C. The temperature regime of the reservoir is favorable for polymer flooding.

#### 3.2. Application of Polymer Flooding Technology

Permeability, porosity, the pore size of the collector are interrelated factors, and their magnitude influences the choice of molecular weight and polymer size (Bourdais *et al.*, 1983). The molecular size of the polymer decreases with increasing salinity of the water while increasing the restriction on permeability. The molecular size of the polymer is selected according to the existing size range of the pore channels. Existing types of polymers for PNP have a limit on the permeability of at least 50 mD and injectivity of at least 50 m<sup>3</sup>/day (Vakhitov *et al.*, 1980; Victorin, 1988). The permeability of the productive horizons of the field (against core, well logging, well test) vary widely from units to several thousand mD. In the areas of water injection, the injectivity is an average of 50 m<sup>3</sup>/day with restriction by the nozzle and can potentially take more than 200 m<sup>3</sup>/day and higher. Existing ranges of permeability and injection well regimes are favorable for polymer flooding (Vlasov *et al.*, 1997; Vlasov *et al.*, 1998; Volkov *et al.*, 1998).

To assess the effectiveness of polymer flooding in this work, we tested two types of polymer: 1) for oil displacement (PF) – AR-RV-1 with a molecular weight of 7.39 million Daltons; 2) for conformance control (CC) – AR-RV-2 with a molecular weight of 15.15 million Daltons. The experiments used real formation water purified from oil products, solids, and iron ions (Table 2). The dynamic viscosity of the solutions was measured on an Anton-Paar automatic high-precision viscometer in the ranges of shear rates of 0-100 s<sup>-1</sup> and temperature of 40°C. Measurement of the rheological properties of each sample was repeated twice and averaged under the condition of the minimal discrepancy; in the opposite case, the measurement was repeated. All samples of the polymer solution were prepared under atmospheric conditions. The results of physico-chemical analyzes and rheological studies are presented in Tables 3-5 and in Figure 4. As follows from the presented tables and figures, associative polymers have high thickening ability, good filterability, excellent solubility, and high resistance to aging under reservoir conditions of the Karazhanbas field.

In this work, a series of filtration studies were carried out to assess the effectiveness of filtration in the low-permeable part of the reservoir, the blocking coefficient of the high-permeable part of the reservoir, and to replace the residual oil after flooding. Bulk models with layered heterogeneous permeability, which are typical for the

Karazhanbas field, were used as a reservoir model. Model size: 4.5x4.5x30cm, permeability by layers: 100/500/1200 mD, thickness by layers: 0.75/3.15/0.6 cm (Figure 5). The viscosity of the model reservoir oil was 881.7 cps, a combination of oil and diesel was used as model oil, the temperature was 28°C. Figures 6-7 and Tables 6-10 show the results of the studies. As follows from the presented table and figure data, these experiments confirm the positive ability of the polymer solution to be filterable in the rock. This can be seen by the pressure gradient of the injection and its stabilization through 7-10 pore volumes of pumping the solution.

The results of filtration studies are presented in Tables 8-10 and Figure 7. As follows from the presented figures and tables, the optimal concentration of AR-RV-1 polymer in water was 2000 mg/l, and the optimal rim size was 0.3 units. Pore volume (PV), the optimal concentration of the CC rim, is 0.1 PV at a concentration of 3000 mg/l of AR-RV-2 polymer. With this design of injection, the maximum increase in the displacement coefficient is reached and amounts to 19.07%.

The thickness of an effective oil-saturated formation is not less than 10 m; weighted average permeability over the thickness of the reservoir is more than 200 mD; formation temperature – not more than 70°C; bedding – more than three layers; the coefficient of variation by bedding is less than 0.5; weighted average current oil saturation – more than 0.45; absence of a gas cap; absence of underlying water; absence or low degree of fracture.

Based on the selection criteria, a site with four conjugate elements of a 7-point waterflooding system was selected. The calculation of development indicators was carried out on the model of non-volatile oil (Black oil model). The prediction of polymer flooding was carried out on the “Polymer flooding” module, with setting the parameters of adsorption on the rock, polymer viscosity, mechanical destruction, resistance coefficient according to the results of laboratory studies of this work.

The forecast of the main technological development indicators was carried out in two ways:

- 1) The basic option is to continue flooding to 12/31/2034, while the injectivity and production rates of the wells remain constant and equal to the levels of December 2018.

- 2) Polymer flooding – from 01/01/2019 to 03/18/2020 injection of a polymer solution AR-

RV-2 with a concentration of 3.000 mg/l (viscosity 561.44 cPz), from 03/19/2020 to 10/24/2023 injection of a polymer solution with a concentration of 2.000 mg/l (viscosity 39.56 cPs), from 10.25.2023 to 12.31.2034 water injection.

In the basic option, by December 31, 2035, cumulative oil production will amount to 514.862 thousand tons, oil recovery factor 26.4%. In the case of polymer flooding, by December 31, 2035, cumulative oil production will amount to 724.2 thousand tons, an oil recovery factor of 37.1%. The increase in oil recovery due to polymer flooding will amount to 10.8%, additional oil production – 209.338 thousand tons. The dynamics of the development indicators for the base case and polymer flooding option are presented in Figure 8.

#### 4. CONCLUSIONS:

The polymer solution AR-RV-2 shows excellent blocking ability of highly permeable channels, on average, when pumping from 0.2 to 0.6 units. The pore volume blocking coefficient is more than 99%. Filtration studies on oil displacement were carried out in three stages:

1. Tests to add oil with a polymer solution of various concentrations after pumping two pore volumes of water in order to determine the optimal ratio of the mobility of displaced and displacing phases and optimizing the concentration (viscosity) of the polymer rim.

2. At the same concentration of the polymer solution according to step 1, after pumping two pore volumes of water, pumping the polymer solution with different volumes of the rim, in order to optimize the rim volume.

3. Modification of the design of rims with the complex effect of PF and CC – pumping of different variants of the rim and polymer concentration (CC) during polymer exposure taking into account stage 1 and 2.

The optimal concentration of AR-RV-1 polymer in water made up 2000 mg/L; the optimal rim size was 0.3 units. Pore volume (PV), the optimal concentration of the runway rim is 0.1 PV at a concentration of 3000 mg/l of AR-RV-2 polymer. With this design of injection, the maximum increase in the displacement coefficient is reached and amounts to 19.07%.

To select a site for the field trial of polymer flooding (PF FT), a two-stage screening of the field was performed according to a number of geological, physical, and technological criteria.

During the first stage, an analysis was made of the current state of development of the field by objects in order to determine the site, and then, during a detailed analysis of the site, waterflooding elements were selected for the water treatment.

The analysis based on the experience of applying polymer flooding in high-viscosity oil fields, laboratory studies and estimated calculations of the expected production in the sector geological and hydrodynamic model shows a decrease in water cut, an increase in oil production, and an increase in current and final oil recovery. An economic analysis, taking into account the existing market situation, shows that the payback index is 4.8 units, and the payback period is 5 years. This direction for increasing oil recovery is promising and requires further testing at the Karazhanbas field.

**Table 1.** The results of physico-chemical analysis of wastewater for pressure maintenance method

| Index   | Results      |
|---|--------------|
| pH medium   | 7.1          |
| Density, g/cm <sup>3</sup>  | 1.018        |
| Calcium content (Ca <sup>2+</sup> ), mg / dm <sup>3</sup>                                 | 1 202.4      |
| Magnium content (Mg <sup>2+</sup> ), mg/dm <sup>3</sup>                                   | 608.0        |
| The amount of potassium and sodium (K <sup>+</sup> +Na <sup>+</sup> ), mg/dm <sup>3</sup> | 7 894.8      |
| Chloride content (Cl <sup>-</sup> ), mg/dm <sup>3</sup>                                   | 15 714.6     |
| Sulfate content (SO <sub>4</sub> <sup>2-</sup> ), mg/dm <sup>3</sup>                      | Not detected |
| Hydrocarbon content (HCO <sub>3</sub> <sup>-3</sup> ), mg/dm <sup>3</sup>                 | 561.2        |
| Mineralization, mg/dm <sup>3</sup>  | 26 008.0     |
| Sulin type  | Cl-Ca        |
| Total water hardness, mg-Equiv/l  | 110.0        |
| Total iron content(Fe <sup>2+</sup> , Fe <sup>3+</sup> ), mg/dm <sup>3</sup>              | 50.4         |

**Table 2.** Physico-chemical analysis of polymers AR-RV-1, AR-RV-2

| Parameter                            | AR-RV-1 |           | AR-RV-2 |           |
|--------------------------------------|---------|-----------|---------|-----------|
|                                      | Fact    | Valuation | Fact    | Valuation |
| Molecular weight, mil. Daltons       | 7.39    | -         | 15.15   | -         |
| The content of the main substance, % | 92.51   | >90       | 90.31   | >90       |
| Degree of hydrolysis, %              | 20.6    | 15-25     | 16.96   | 15-25     |
| Intrinsic viscosity, dl/g            | 12.6    | 10-30     | 22.3    | 10-25     |
| Insoluble residue, %                 | 0.88    | <1        | 0.31    | <1        |
| Filterability, ea                    | 0.6     | <=1.5     | 1.04    | <=1.5     |
| Dissolution time, hr                 | 3       | 3         | 3       | 3         |
| Compliance with the requirements     | Match   |           | Match   |           |

**Table 3.** Viscosity of polymers at various concentrations

| Polymer concentration, ppm | Dynamic viscosity at 7,34c-1, cPs |              |
|----------------------------|-----------------------------------|--------------|
|                            | AR-RV-2 (CC)                      | AR-RV-1 (PF) |
| 1000                       | 27.5                              | 13.3         |
| 2000                       | 242.6                             | 47.0         |
| 3000                       | 540.6                             | 70.0         |

## RESUMO

O acondicionamento e armazenamento inadequados das laranjas (*Citrus sinensis*) pode resultar na deterioração e crescimento de microrganismos, incluindo *Aspergillus* spp. estes fungos são onipresentes e crescem em frutos após a colheita. Certas espécies de *Aspergillus* produzem toxinas que podem afetar a saúde de seres humanos e animais. O presente estudo teve como objetivo isolar *Aspergillus niger* de laranjas mofadas, testar sua capacidade de produzir aflatoxina pelo método Saito e Machida e avaliar sua toxicidade de alguns parâmetros bioquímicos em ratos brancos machos. Além disso, a eficiência da inibição de nanopartículas de prata (AgNPs), *Pseudomonas fluorescens* e *Bacillus circulans* foi avaliada contra isolados de *A. niger*. O resultado da triagem de todos os nove isolados pelo método Saito e Machida demonstrou a capacidade de um isolado produzir aflatoxinas em grandes quantidades. O filtrado desse isolado mostrou um aumento no nível de enzimas GPT e GOT (24,2 U/ml e 18,3 U/ml), respectivamente, em comparação com o isolado de aflatoxinas não produtoras e o controle (16,6 e 12,2 U/ml) e (8,5 e 8,2 U/ml), respectivamente. O nível de glicose foi aumentado para (130,2 mg/dl) nos ratos tratados com o filtrado do isolado produtor de aflatoxinas em comparação com (95 mg/dl) e (86,4 mg/dl) tratados com o filtrado do isolado não produtor e o controle respectivamente. Além disso, o nível de LDL-colesterol foi reduzido para 120,2 mg/dl e 101 mg/dl com o produtor de filtrado e os isolados de aflatoxinas não produtoras, respectivamente, em comparação com 144,3 mg/dl para o controle. Os AgNPs mostraram um efeito inibitório contra o crescimento de *A. niger*, com a maior zona de inibição de 28,38 mm a uma concentração de 100 µl. Por outro lado, *Pseudomonas fluorescens* e *Bacillus circulans* também mostraram uma excelente taxa de inibição (100%) na concentração de 2 g/L do filtrado do fungo. Esses resultados expuseram que os AgNPs são capazes de inibir *A. niger* e, consequentemente, os AgNPs podem ser usados como um candidato antifúngico.

## ABSTRACT

The improper packaging and storage of oranges (*Citrus sinensis*) may result in decay it and growth of microorganisms, including *Aspergillus* spp. these fungi are omnipresent and growing on post-harvest fruits. Certain species of *Aspergillus* produce toxins that can affect humans and animals health. This study aimed to isolate *Aspergillus niger* from moldy oranges, test its ability to produce aflatoxin using the Saito and Machida method, and evaluation of their toxicity of some biochemical parameters in white rat males. Moreover, the inhibition efficiency of silver nanoparticles (AgNPs), *Pseudomonas fluorescens*, and *Bacillus circulans* were assessed against *A. niger* isolates. The outcome of screening all nine isolates by the Saito and Machida method has shown the capability of one isolate to produce aflatoxins in large amounts. The filtrate of this isolate showed an increase in the level of GPT and GOT enzymes (24.2 U/ml and 18.3 U/ml) respectively, compared to the

non-producing aflatoxins isolate and the control (16.6 and 12.2 U/ml) and (8.5 and 8.2 U/ml) respectively. Glucose level was increased to (130.2 mg/dl) in the rats treated with the filtrate of aflatoxins producer isolate compared to (95 mg/dl) and (86.4 mg/dl) treated with the filtrate of the non-producer isolate and the control respectively. Additionally, the LDL-cholesterol level was reduced to 120.2 mg/dl, and 101 mg/dl with the filtrate producer and the non-producer aflatoxins isolates respectively compared to 144.3 mg/dl for the control. AgNPs have shown an inhibitory effect against *A. niger* growth with the largest inhibition zone of 28.38 mm at a concentration of 100µl was recorded. On the other hand, *Pseudomonas fluorescens* and *Bacillus circulans* have also shown an excellent inhibition rate (100%) at the concentration of 2 g/L of the fungus filtrate. These results exposed that AgNPs are able to inhibit *A. niger*, and consequently, AgNPs can be used as an antifungal candidate.

## المخلص

التغليب والتخزين غير المناسبين للبرتقال (*Citrus sinensis*) قد يؤدي الى تحلله ونمو الكائنات الحية الدقيقة بما في ذلك نوع الرشاشيات هذه الفطريات منتشرة في كل مكان وتنمو على فاكهة ما بعد الحصاد. تنتج بعض انواع الرشاشيات السموم التي يمكن أن تؤثر على صحة الإنسان والحيوان. تهدف هذه الدراسة إلى عزل فطريات الرشاشية السوداء من البرتقال المتعفن، اختبار قدرتها على إنتاج الأفلاتوكسين باستخدام طريقة Saito و Machida، وتقييم سميتها لبعض المعايير الكيموحيوية في ذكور الجرذان البيضاء. علاوة على ذلك، تم تقييم كفاءة تثبيط الجسيمات النانوية للفضة، بكتيريا الزائفة المتألقة و عصوية سيركيولانز ضد عزلات فطر الرشاشية السوداء. أظهرت نتائج مسح جميع العزلات التسعة بطريقة Saito و Machida قدرة عزلة واحدة على إنتاج الأفلاتوكسين بكميات كبيرة. أظهر راشح هذه العزلة زيادة في مستوى إنزيمات GOT و GPT (24.2 وحدة/مل و 18.3 وحدة/مل) على التوالي، مقارنة بالعزلة غير المنتجة للأفلاتوكسين ومعامل الضبط (16.6 و 12.2 وحدة/مل) و (8.5 و 8.2 وحدة/مل) على التوالي. مستوى الجلوكوز ازداد إلى (130.2 مجم/ديسيلتر) في الجرذان المعاملة براشح العزلة المنتجة الأفلاتوكسين مقارنة بـ (95 مجم/ديسيلتر) و (86.4 مجم/ديسيلتر) المعاملة براشح العزلة غير المنتجة والمجموعة الضابطة على التوالي. بالإضافة إلى ذلك، أنخفض مستوى الكوليسترول الضار إلى 120.2 مجم/ديسيلتر و 101 مجم/ديسيلتر المعاملة مع راشح العزلات المنتجة وغير المنتجة للأفلاتوكسين على التوالي مقارنة بـ 144.3 مجم/ديسيلتر للمجموعة الضابطة. أظهرت الجسيمات النانوية للفضة تأثير مثبط ضد نمو فطر الرشاشية السوداء مع أكبر منطقة تثبيط 28.38 ملم بتركيز 100 ميكرو لتر. من ناحية أخرى، أظهرت أيضا كل من بكتيريا الزائفة المتألقة وعصوية سيركيولانز معدل تثبيط ممتاز (100 %) عند تركيز 2 جم/لتر من راشح الفطر. كشفت هذه النتائج أن الجسيمات النانوية للفضة قادرة على تثبيط فطر الرشاشية السوداء وبالتالي يمكن ترشيحها لاستخدامها كمضاد للفطريات.

**الكلمات المفتاحية:** البرتقال، فطر الرشاشية السوداء، المعايير الكيموحيوية، خارج الجسم، جسيمات الفضة النانوية.

## 1. INTRODUCTION

Orange (*Citrus sinensis*) is a type of citrus fruit that belongs to the family Rutaceae. It is one of the winter fruits with an excellent source of vitamin C, in addition to some other vitamins such as B1, B2, B3, B5, B6, A, and E. Furthermore, many other essential nutrients are found in orange, for example, the essential potassium, calcium, iron, zinc, and phosphorus (Butu and Rodino, 2019). Orange is very rich in natural antioxidants, and phenolic compounds, being an important source of flavanones, particularly hesperidin and naringenin. In addition to the hydroxycinnamic acids, orange has a high content of carotenoids, which is an important dietary source of vitamin A carotenoids ( $\beta$ -carotene,  $\alpha$ -carotene, and  $\beta$ -cryptoxanthin) and antioxidant carotenoids ( $\beta$ -carotene,  $\beta$ -cryptoxanthin, zeaxanthin, and lutein) and numerous volatile organic compounds producing orange aroma, including aldehydes, esters, terpenes, alcohols, and ketones (Perez-Cacho and Rouseff, 2008; Galaverna and Dall'Asta, 2014; Aschoff et al., 2015; Tamokou et al., 2017; Capurso et al., 2018). Orange peel is plentiful in flavonoids, including methylated derivatives such

as PMFs, which exhibited strong anti-inflammatory effects at both gene expression and enzyme activity levels (Yu et al., 2004; Sandhy et al., 2011; Manthey et al., 1999).

Previous studies have shown that 20% of processed fruits and vegetables are lost due to spoilage (Mailafia et al., 2017). Oranges withstand at room temperature for long enough but can last up to three weeks if kept in the refrigerator (Butu and Rodino, 2019).

The improper handling, packaging, warehousing, and transportation may result in decomposition and growth of microorganisms. The decay becomes activated because of changes in the physiological state of the fruits, as the pH level becomes lower, in addition to any other reasons, for instance, the high moisture content and the high nutrient composition which both assist in making the fruits very susceptible to attack by pathogenic fungi, which at the end causing rot, and may also make the fruits unfit for consumption by producing mycotoxins (Moss, 2002; Jay, 2003). Common air molds such as *Penicillium* and *Aspergillus* species may enter into the tissues and causing loss during packaging. The extensive production of spores by these pathogens allows it to maintain its

presence wherever fruits were handled, including field, packinghouse, equipment, storage rooms, transit containers, and market place (Ismail and Zhang, 2004).

*Aspergillus niger* is a parasitic fungus that penetrates the tissues of citrus fruits through micro-wounds and bruises. *Aspergillus* rot has a black mold on the fruits, and even adjacent fruits are infected as the spores contaminate the whole lot. High temperatures (the most favorable temperature is 25–40 °C) and high relative humidity support these organisms to develop. *Aspergillus niger* causes rapid decay and spreads at 30–35 °C very quickly. *Aspergillus* does not get below 15 °C, and in that respect is no increase at all under refrigerated conditions. The fungus is very sensitive to temperature. Interestingly, acid lime fruit stored at 30–35 °C develops very high rates of decay and sporulation when infected, while fruits from the same lot stored under cooled conditions (8–10 °C) is free of decay. *Aspergillus niger* is increasingly widespread in Indian citrus fruits (Milind, 2008).

Nanoparticles are one of the materials that reflect an excessive interest due to their properties that make them an excellent candidate for numerous castigations such as medicine, biology, bioengineering, and much more. Silver, copper, gold, magnesium, titanium has been used as nanoparticles against different species of microbes. However, the silver nanoparticles are presently interesting, and the attention to this metal is increased to be used in many uses, including antifungal agents (Gong *et al.*, 2007; Ahmad *et al.*, 2006; Aldujaili and Banoon, 2020).

Silver nanoparticles (AgNPs) are metal structures at the nanoscale and the most important choice for solving various medical problems due to their biocompatible chemical structure, inertness, oxidation resistance, and the broad spectrum of antimicrobial activity against a diverse range of bacteria and fungi. Additionally, silver nanoparticles have very little chance of developing microbial strains resistant to drugs (Mallmann *et al.*, 2015). Silver nanoparticles, therefore, have synthesized as potential antimicrobial material against fungi and bacteria to treat many of the infectious diseases caused by human pathogens and to eliminate the multidrug resistance problems (Prabhu and Poulouse, 2012; Salem *et al.*, 2015; Gudikandula *et al.*, 2017).

This study aimed to isolate *A. niger* from fruits of moldy oranges, test there ability to produce aflatoxins using the Saito and Machida

method, and evaluation the toxicity of *A. niger* on some biochemical parameters in white rat males and assessment the inhibition efficiency of silver nanoparticles, *Pseudomonas fluorescens* and *Bacillus circulans* against *A. niger* isolate that produced the aflatoxins.

## 2. MATERIALS AND METHODS

### 2.1 Bacterial model species used in this study:

*Pseudomonas fluorescens* and *Bacillus circulans* were used in this study. Both strains were identified and confirmed by applying the biochemical tests and using the VITEK-2 compact system using GP and BCL cards, respectively (Garrrity *et al.*, 2004).

### 2.2 *Aspergillus niger* isolated from decayed orange fruits

*Aspergillus niger* was isolated from moldy orange fruits which were surface disinfected with 4% sodium hypochlorite for 2 min, the surface of disinfected fruits were plated on sterilized Petri dishes contained Potato Dextrose Agar (PDA) which was prepared according to (Mackie 1996). The plates were incubated at 28 °C for seven days. The identification of *Aspergillus niger* isolates was based on cell and colony morphology characteristics according to the method described by (Klich 2002; Samuel *et al.*, 2015). At the final stage of the incubation period, the percent of the appearance of fungus was calculated by Equation no.1.

### 2.3 Detection of the capacity of *Aspergillus niger* isolates to produce aflatoxins

Nine isolates of *A. niger* were obtained from a total of 15 fungal samples. The ability of these isolates to produce the aflatoxins was tested according to (Saito and Machida, 1999) on Coconut Extract Agar (CEA) medium and ammonia solution at a concentration of 20%. The plates were incubated at 28 °C for 7-14 days. The CEA medium was prepared according to (Alvarez-Barrea *et al.*, 1982).

### 2.4 The effect of the *A. niger* Filtrate on white rat males

#### 2.4.1 Preparation of Fungal Filtrate

Three flasks (500 ml) were prepared, and 250 ml from liquid yeast extract medium was

added to each flask. After the sterilization and cooling of the medium, two discs of *A. niger* isolate that produced the aflatoxins were added into the first flask, two discs of *A. niger* isolate that does not produce the aflatoxins were added into the second flask. The third flask that does not contain any fungi isolates was used as a control treatment. All three flasks were incubated at  $25 \pm 2$  °C for three weeks. After the incubation period, the components of the fungus (fungus and spores) were separated using turmeric papers (Whatman NO. 4) with the Buchner suppression. The fungal filtrate for both isolates were then collected and used in the dosages of animals (Al-Janabi, and Al-gumaili, 2009).

#### 2.4.2 Preparation of Laboratory animals

In this experiment, 15 white male rats (10 weeks of age, average weight: 200 g) were tested. They were obtained from the University of Kufa, Najaf City, Iraq. The rats were acclimatized for three weeks and housed in polyethylene boxes with bedding of wood shavings. They were maintained under standard conditions, which included a temperature of approximately 22-24 °C with a regular 12h light/12h dark cycle. All rats were given standard rodent pellet food and water. These rats were separated into three groups. Each group includes five rats:

Group A: 5 rats were orally injected with *A. niger* filtrate produced the aflatoxins and in a dose of (1 ml/ 100 g /day) per body weight.

Group B: 5 rats were orally injected with *A. niger* filtrate non-produced the aflatoxins at the same concentration and method mentioned in group A.

Group C: 5 rats were treated with filtrate of the third flask that does not contain any fungi isolates, and the same concentration and method mentioned in group A, treated as a control.

The dosage was taken every 48 hours by oral gavage (Waynforth and Flecknall, 1980), after three weeks of the experiment, the animals were left for three days, the animals were anesthetized and sacrificed.

#### 2.5 Biochemical parameters

The biochemical parameters, including the determination of the GOT and GPT levels, determination of glucose level in serum, and estimate the level of cholesterol in the blood, were carried out according to the manufacturer's instructions (Linear Chemical, Spain).

## 2. 6 Preparation of Silver Nanoparticles

Silver nanoparticles powder (Shanghai Ximeng New Materials Technology co., Ltd, China) Type 2, Purity > 99.95%, with particle size (50nm) was used, The aqueous solution of silver nanoparticles was prepared by dissolving 20 mg of AgNPs in 100 ml of deionized water. The resulted solution was stirred well by the sonication process to obtain a homogeneous solution and to avoid the accumulation of the nanoparticles. This mixture was then autoclaved at 15 psi pressure, 121 °C for 5 minutes. The solution was yellowish, the serial dilution concentrations of silver nanoparticles were required in this study prepared 25, 50, 75, and 100 (µl) (Mohanty *et al.*, 2012).

#### 2.6 Antifungal activity of the silver nanoparticles

The procedure described by (Alananbeh *et al.*, 2017) was followed here with some modification; by preparation of the PDA medium. The PDA was sterilized in the autoclave and poured into 6 Petri dishes. The dishes were then inoculated with *A. niger* isolate, which produced the aflatoxin. The fungicidal activity of the silver nanoparticles was determined using the agar well diffusion assay method. All the dishes were incubated at  $25 \pm 2$  °C for five days, and the plates were examined for evidence of zone of inhibition, which appeared as a clear area around the wells, the diameter of such zones of inhibition was measured using a meter ruler.

#### 2. 7 Antifungal activity for the bacteria used in this study

The PDA was prepared and distributed in three flasks at 250 ml per flask. The growth medium was autoclaved for 15 min, after cooling the flasks, the bacterial concentrations (1, 2) g/L were added. The contents of each flask were poured into six dishes, and all dishes were incubated at  $25 \pm 2$  °C from 5 to 7 days (Leben *et al.*, 1987). The dishes were vaccinated with *A. niger* isolate produced the aflatoxins, but the content of the third flask used without bacteria as control. The dishes were then incubated at  $25 \pm 2$  °C for a week. The percentage inhibition of growth of the fungus was calculated using Equation 2 (Kra *et al.*, 2009). In Equation no. 2, A, and B are the average diameter of fungal growth on the control medium with and without bacteria, respectively.

## 2.8 Statistical Analysis

The obtained data were statistically analyzed using the software SPSS Version 6. Treatment averages were compared at the  $p \leq 0.05$  level of probability using LSD (Norris, 1999).

## 3. RESULTS AND DISCUSSION

### 3.1 Isolation of Fungi from the orange fruits

Nine isolates were obtained from *A. niger* with an occurrence of 60%. Also, five isolates of *A. flavus* were obtained with 33.33%, while one isolate from *Rhizopus stolonifer* was obtained with 6.66% (Figure 1). These results are close to the results reported by (Reuther, 1967), who confirmed the ability of *A. niger*, *A. flavus*, and *Rhizopus* to infect orange and apple fruits after harvesting. *A. niger* has the highest frequency since it is considered as one of the widespread fungi in different soils, and it can tolerate drought and a wide range of wet tension (Hillocks and Waller, 1997). Also, *A. niger* spores have been found to withstand at high temperatures (up to 50 °C) (Gabler *et al.*, 2004). The present study agreed with (Mailafia *et al.*, 2017), the authors found that *Aspergillus niger* had the highest occurrence in pineapple, watermelon, oranges, pawpaw, and tomatoes with a frequency of 38%. The percentage of *Rhizopus* as the lowest agree with (Muhammad *et al.*, 2018) found the *Rhizopus* spp (20%), according to other fungi that isolated from sweet orange.

**Figure 1.** The frequency rate of isolated fungi from orange fruits

### 3.2 Detection of the ability of *A. niger* isolates to produce aflatoxins

The results of the chemical detection using the coconut medium and ammonia have shown that some of the *A. niger* isolates were able to produce aflatoxins (Table 1). It was noticed that the isolate no. 2 produced large

quantities of aflatoxins while isolates no.5 and no. 8 produced small quantities of aflatoxins, other isolates were negative for aflatoxin production. The difference in the ability of the isolates to produce aflatoxins, as mentioned by (Saito and Machida, 1999), depends on the degree of red color, the dark red indicates its ability to produce larger quantities of aflatoxins, and this result agrees with (Scott and Trucksess, 1997) who confirmed the ability of *Aspergillus niger*, *Aspergillus ruber*, *Aspergillus wentii*, and *Aspergillus ostianus* to produce aflatoxins but in lower quantities of *Aspergillus flavus*. Also (Hasan, 2000) reported that some of the *A.niger* isolates that were isolated from apple fruits could produce aflatoxins. A study by (Akinola *et al.*, 2019) reported that twenty-three isolates from *Aspergillus* were positive for aflatoxin production. Some *A. niger* strains have been reported to produce potent mycotoxins called ochratoxins, which can be harmful to humans and animals (Mailafia *et al.*, 2017).

**Table 1.** *Aspergillus niger* isolates producing and non-producing the aflatoxins

| No. of <i>niger</i> isolates | A. Quantities Aflatoxins | The ability of aflatoxins production |
|------------------------------|--------------------------|--------------------------------------|
| An1                          | -                        | -                                    |

An6: *A.niger* isolate that non-producing of aflatoxins, and it used in this study

### 3.3 The toxic effects of the *A. niger* Filtrate on white rat males

#### 3.3.1 Effect on GPT and GOT enzymes

Figures (2 and 3) show the effect of two isolates of *A. niger* on GPT and GOT enzymes. The *A. niger* isolate that produced the aflatoxins increased the activity of the GPT and GOT to 24.2 U/ml and 18.3 U/ml, respectively. In

contrast, the *A. niger* isolate that non-produced the aflatoxins increased the activity of two enzymes to 16.6 U/ml and 12.2 U/ml, respectively, compared to the control treatment of 8.5 and 8.2 U/ml.

The increase in the activity of enzymes in the serum of treated animals can be explained by the fungal filtrate that may have an effect on the liver cells containing these enzymes, which leads to releasing the enzymes to the blood. This mechanism can also affect other organs such as kidneys and membranes of the endoplasmic network, resulting in disruption of the bio-transport system in the body (Meerdink, 2004). This study agrees with (Al- Janabi and Al-gumaili, 2009), who showed that the isolate of *A. flavus*, which produces aflatoxins, significantly increased the level of GPT and GOT to 22.3 and 14.4 U/ml compared to the control treatment of 8.3 and 8.2 U/ml respectively.

**Figure 2.** Effect of *A. niger* isolates on GPT, A: aflatoxins production isolate B: aflatoxins non-production isolate C: control

**Figure 3.** Effect of *A. niger* isolates on GOT, A: aflatoxins production isolate B: aflatoxins non-production isolate C: control

### 3.3.2 Effect on Glucose and cholesterol level

The Table (2) shows the results of the effect of the fungal filtrate of *A. niger* isolate on the glucose level, which had caused an increase in the glucose level to (130.2 mg/dl) in the animals that treated with the *A. niger* isolate which producing the aflatoxins and to (95 mg/dl) with the non-producing isolate compared to the

control which was 86.4 mg/dl.

Mechanisms of increasing of the concentration of glucose during aflatoxicosis are not well understood, but this may be due to hormone alteration or stress condition that occurs during aflatoxicosis, which is known to raise blood sugar by altering insulin action. Hyperglycemia in the presence of cirrhosis and some other liver disease may be greater in degree and more prolonged (Yeung and Wang, 1974). The reason of the high sugar level may be due to the metabolic products of the *A. niger* that is normally interfered with the metabolic pathway of glucose and influences the enzymes responsible for regulating the amount of sugar in the blood, including insulin, this is indicated by (WHO, 2003; Sacks *et al.*, 2002). A study by (Mor *et al.*, 2017) reported that Ochratoxin A from *Aspergillus* leads to decreases in insulin levels and increases in blood glucagon and glucose levels. This phenomenon, due to the Ochratoxin A, cause pancreatic damage on the Langerhans islet cells and predispose rats to diabetic Mellitus.

The blood glucose decrease during the course of aflatoxicosis, then after 30 days of treatment, blood glucose levels slowly increased, as indicated by decreasing the concentration of glycogen in the liver, kidney, and heart, which may result from the reducing tissue glucose intake (Busby and Wogan, 1981; Kolhe, 2016).

For the LDL cholesterol, the filtrate of *A. niger* isolate that produced aflatoxins reduced the cholesterol level to 120.2 mg/dl while the non-productive isolate reduced to 101 mg/dl compared to the control with a cholesterol level of 144.3 mg/dl. Hussein and Brasel (2001); Pusztahelyi *et al.* (2015), noted that fungal secondary metabolic products contain compounds that have a high affinity for the mitochondrial membrane causing a rapid crash and also inhibit the protein transport chain, this inhibition may lead to a reducing in the production of energy that required to synthesize cholesterol. Also, Javed *et al.* (2014) found that seven indigenously of *Aspergillus* strains were able to produce cholesterol-lowering drug lovastatin, and the *Aspergillus terreus* strain showed maximum production, the optimized lovastatin was extracted from fermented broth and orally administered to rats. It was concluded that fermented lovastatin effectively lowers the cholesterol level of rats, while Rashid *et al.* (2013) found that the highest lovastatin production was produced by *Aspergillus niger* SAR strain.

**Table 2.** Effect of *A. niger* isolates that produced and non-produced of aflatoxins in the level of sugar and cholesterol in white male rats

| Type of treatment                                       | Blood sugar level (mg/dl) | Blood cholesterol level (mg/dl) |
|---|---------------------------|---------------------------------|
| <i>A. niger</i> isolate that produced of aflatoxins     | 130.2                     | 120.2                           |

| L.S.D(0.05)   | 0.34                      | 0.16                            |

Note: Each number represents three replicates.

### 3.4 The efficiency of silver nanoparticles in the inhibition of *A.niger* radial growth

The results indicated that the silver nanoparticles were able to inhibit *A. niger* growth. The diameters of the inhibition zone (11.51, 16.28, 23.71, 28.38 mm) at concentrations 25, 50, 75, and 100 (µl), respectively, as shown in Figure 4. Previous studies described the effective applications of silver nanoparticles as an inhibitory agent at different concentrations against fungi such as *Alternaria alternate*, *Fusarium*, *Aspergillus* species, *Trichophyton mentagrophytes*, and *Candida* sp. (Gao *et al.*, 2012; Noorbakhsh *et al.*, 2011; Bocate *et al.*, 2019). Also, a study by (Alananbeh *et al.*, 2017) found that the gradual reduction in growth was clear in both *Aspergillus* species as the silver nanoparticles concentrations were increased, where *A. terreus* had higher reduction compared to *A. niger*. The silver nanoparticles are possible to be used as antifungal substances. The AgNPs mode of action has several explanations. Metal depletion is one of the AgNP's modes of action that forms irregularly shaped pits in the outer membrane and changes membrane permeability caused by the progressive release of molecules and membrane proteins from lipopolysaccharides (Amro *et al.*, 2000). Ag-generated free radicals have been documented using the Ag nanoparticles Electron Spin Resonance (ESR). Ag nanoparticles' antimicrobial function has to do with the creation of free radicals and subsequent free radical-induced damage to the membrane (Danilczuk *et al.*, 2006). Toxicity is concentration-

and size-dependent. Moreover, the effectiveness of AgNPs against microbes depends on their shapes and sizes (Panáček *et al.*, 2009). In this study, 50nm was the diameter of the AgNPs, yet it inhibited the *Aspergillus niger*. This could be explained by the fact that larger particles of AgNPs can persist longer and could serve as continuous Ag ions source Dobias and Bernier-Latmani (2013), and this agrees with Alananbeh *et al.* (2017).

### 3.5 The efficacy of *Pseudomonas fluorescens* in inhibition of the radial growth of *A. niger*

The results showed the ability of the *P. fluorescens* to inhibit the growth of *A.niger* isolate that produced aflatoxins with inhibition rate attained 100% at 2 g/L, as shown in figure (5). These results are consistent with many studies such as (Hassan, 2012), the inhibitory capacity of *P. fluorescens* to their ability to produce multiple types of antibiotics including Oligomycine, Oomycine, Phenazine-1-carboxylic acid (PCA), Pyoluterin (Plt) and Pymolnitrin (Pln) that the most important antibiotics produced by *P. fluorescens* in contrast with *Fusarium graminearum* and *Fusarium moniliforme* (Pal *et al.*, 2001). Also, a study conducted by (Mathre *et al.*, 2003), it was reported that *P. fluorescens* was capable of producing 2,4-Diacetylphloroglucinol 2,4-DPG), which inhibits the growth of many fungi-causing diseases.

### 3.6 The efficacy of *Bacillus circulans* with different concentrations in inhibition of the radial growth of *A.niger*

*Bacillus circulans* proved highly effective in inhibiting the growth of *A. niger* isolate that producing aflatoxins with an inhibition rate attained 100% at 2 g/L, as shown in Figure 6. The effect of *B. circulans* may occur due to the mechanisms that bacteria possess against pathogenic fungi, including *A. niger*. These mechanisms include the production of antifungal compounds, many of these compounds, such as A Zwittermicin, Kanosamine, and Bacillomycin. These compounds affect fungal cell components, such as enzymes and proteins (McSpadden Gardener, 2004).

*Bacillus* species can also produce some enzymes that analyze cellular walls of fungus such as chitinase, which dissolves the substance of chitin, the base component of the cellular walls of fungus (Peraica *et al.*, 1999). Also (Idriss *et al.*, 2002) demonstrated the ability of some species of *Bacillus* to produce the phytase that broken of

Phytic acid in the cell walls of many fungi.

#### 4. CONCLUSIONS

The outcomes of the present study found that one isolate of *A.f A. niger* was able to produce aflatoxins by using the Saito and Machida method.

The isolate of *A. niger* that was producing aflatoxins, which effect on GPT and GOT enzymes that cause increased the level of the two enzymes compared to the isolate of *A. niger* that non-producing aflatoxins and the control treatment.

The results exposed that the silver nanoparticles were able to inhibit *A.niger* isolates growth at concentrations of 25, 50, 75, and 100 (µl). AgNPs can be used as antifungal substances. They considered as less harmful and cost-efficient than other methods for preparing the Nanoparticles.

The results also showed the efficacy of *Pseudomonas fluorescens*, and *Bacillus circulans* in the inhibition of the *A. niger* isolates growth when they used in the concentration of 2 g/L.

## RESUMO

A interação de partículas neutras de gás de energias térmicas (moléculas e átomos) com a superfície do sólido é acompanhada por radiação nas partes visível e infravermelha do espectro. Nesse caso, a superfície do sólido atua como um catalisador para as reações de recombinação de partículas de gás. Neste contexto, é interessante a possibilidade de excitar a luminescência durante a oxidação catalítica do monóxido de carbono diretamente pela forma atômica de oxigênio pré-adsorvido na superfície do sólido. Os métodos cinéticos e espectrais foram utilizados para estudar a luminescência resultante da oxidação catalítica do monóxido de carbono pela forma atômica de oxigênio pré-adsorvido na superfície do sólido – uma amostra de  $\alpha$ -willemite  $\text{Zn}_2\text{SiO}_4:\text{Mn}^{2+}$ . As principais etapas dos mecanismos de recombinação entre as partículas dos adsorbatos são estabelecidas. As transições eletrônicas em complexos de adsorção e no íon ativador foram identificadas. Durante o processo de entrada, a temperatura da amostra foi mantida pelo sistema de controle eletrônico de alta velocidade constante da corrente do aquecedor. Isso ajudou a evitar os efeitos térmicos colaterais. As principais etapas dos mecanismos de recombinação entre as partículas dos adsorbatos são estabelecidas. As transições eletrônicas em complexos de adsorção e no íon ativador foram identificadas. Verificou-se que a excitação da luminescência ocorre em duas etapas principais, um pouco deslocadas no tempo. O mecanismo de duas etapas da oxidação catalítica do monóxido de carbono na superfície da  $\alpha$ -willemite pelo oxigênio atômico pré-adsorvido permite descrever consistentemente a luminescência observada neste caso. Este tipo de luminescência tem a perspectiva no estudo dos mecanismos de oxidação catalítica do monóxido de carbono.

## ABSTRACT

The interaction of neutral gas particles of thermal energies (molecules and atoms) with the surface of a solid is accompanied by radiation in the visible and I.R. parts of the spectrum. In this case, the surface of a solid body acts as a catalyst for the recombination reactions of gas particles. In this connection, the possibility of exciting luminescence during the catalytic oxidation of carbon monoxide directly by the atomic form of oxygen pre-adsorbed on the surface of a solid is of interest. Kinetic and spectral methods were used to study the luminescence arising from the catalytic oxidation of carbon monoxide by the atomic form of oxygen pre-adsorbed on the surface of a solid – a sample of  $\alpha$ -willemite  $\text{Zn}_2\text{SiO}_4:\text{Mn}^{2+}$ . The main stages in the mechanisms of recombination between adsorbate particles are established. Electronic transitions in adsorption complexes and the activator ion have been identified. During the filling process, the sample temperature was maintained by a constant high-speed electronic control system of the heater current. This made it possible to avoid thermal

side effects. The main stages in the mechanisms of recombination between adsorbate particles are established. Electronic transitions in adsorption complexes and the activator ion have been identified. It was found that luminescence excitation proceeds in two main stages, somewhat time-shifted. The two-stage mechanism for the catalytic oxidation of carbon monoxide on the surface of  $\alpha$ -willemite with pre-adsorbed atomic oxygen allows a consistent description of the luminescence observed in this case. This type of luminescence has the prospect of using for studying the mechanisms of catalytic oxidation of carbon monoxide.

## АННОТАЦИЯ

Взаимодействие нейтральных газовых частиц тепловых энергий (молекул и атомов) с поверхностью твердого тела сопровождается излучением в видимой и инфракрасной частях спектра. При этом поверхность твердого тела выступает в роли катализатора реакций рекомбинации газовых частиц. В связи с этим вызывает интерес возможность возбуждения люминесценции при каталитическом окислении монооксида углерода непосредственно атомарной формой кислорода, преадсорбированной на поверхности твердого тела. Кинетическими и спектральными методами исследована люминесценция, возникающая при каталитическом окислении монооксида углерода атомарной формой кислорода, преадсорбированной на поверхности твердого тела – образца  $\alpha$ -виллемита  $\text{Zn}_2\text{SiO}_4\text{:Mn}^{2+}$ . Установлены основные стадии в механизмах рекомбинации между частицами адсорбатов. Идентифицированы электронные переходы в адсорбционных комплексах и в ионе активатора. В процессе напуска температура образца поддерживалась постоянной быстродействующей электронной системой регулирования тока нагревателя. Это позволило избежать побочных тепловых эффектов. Установлены основные стадии в механизмах рекомбинации между частицами адсорбатов. Идентифицированы электронные переходы в адсорбционных комплексах и в ионе активатора. Было обнаружено, что возбуждение люминесценции происходит в два основных этапа, несколько смещенных во времени. Двухстадийный механизм каталитического окисления оксида углерода на поверхности  $\alpha$ -виллемита предварительно адсорбированным атомарным кислородом позволяет последовательно описать люминесценцию, наблюдаемую в этом случае. Этот тип люминесценции имеет перспективу использования для изучения механизмов каталитического окисления оксида углерода.

**Ключевые слова:** *кристаллофосфор,  $\alpha$ -виллемит, оксид углерода, кинетика люминесценции, спектр люминесценции.*

## 1. INTRODUCTION

The interaction of neutral gas particles of thermal energies (molecules and atoms) with the surface of a solid is accompanied by radiation in the visible and I.R. parts of the spectrum (Rufov *et al.*, 1966; Volkenstein *et al.*, 1976; Arnold and Coleman, 1988; Formalev *et al.*, 2019; Radyuk *et al.*, 2019). In this case, the surface of a solid body acts as a catalyst for the recombination reactions of gas particles. Claydel and his coworkers introduced the concept of cathodoluminescence (Breysse *et al.*, 1978) to denote the glow of a solid during a catalytic process on its surface. In particular, in (Breysse *et al.*, 1978; Lurie *et al.*, 2017), it is a question of chemiluminescence arising during the (Equation 1) catalytic process on the  $\text{ThO}_2$  surface activated by rare-earth ions  $\text{Pr}^{3+}$ ,  $\text{Eu}^{3+}$ ,  $\text{Dy}^{3+}$  and  $\text{Gd}^{3+}$ . The interpretation of this type of luminescence is given in the model of the energy bands of a solid with allowance for the local levels induced on the surface by the adsorbate (Achatz *et al.*, 2011). Radiative transitions are supposed from the  $\text{O}^-$  level formed

by the dissociative charged form of molecular oxygen adsorption to the  $\text{CO}^+$  level in the band gap and from the conduction band to the activator level.

In this connection, the possibility of exciting luminescence during the catalytic oxidation of carbon monoxide directly by the atomic form of oxygen pre-adsorbed on the surface of a solid and, thereby, obtaining more detailed information on the mechanism of catalytic oxidation of carbon monoxide is of interest (Kharisov and Kharissova, 2019). As an adsorbent,  $\alpha$ -willemite  $\text{Zn}_{1.98}\text{Mn}_{0.02}\text{SiO}_4$  was selected (sample FGI-520-1 of crystallophosphorus  $\text{Zn}_2\text{SiO}_4\text{:Mn}^{2+}$ , synthesized at the State Institute of Applied Chemistry, Russian Federation). Due to the high luminescence efficiency during cathodic and photoexcitation, chemical and thermal stability, this crystallophosphorus is widely used in optoelectronic technology and lighting devices (Juanjuan *et al.*, 2015; Ni *et al.*, 2018). The morphology, phase composition, and structure of the crystal lattice have been well studied for

$\text{Zn}_2\text{SiO}_4\text{:Mn}^{2+}$ , and the main electronic transitions in spectral laws have been determined (Palumbo and Brown, 1970; Stevels and Vink, 1974; Dove *et al.*, 1981; Hess and Krautz, 1981; Rivera-Enríquez *et al.*, 1981; Formalev *et al.*, 2018; Skvortsov *et al.*, 2014). In addition,  $\text{Zn}_2\text{SiO}_4\text{:Mn}^{2+}$  demonstrates a clear ability for radical recombination luminescence upon excitation by atomic gases (Rufov *et al.*, 1966; Barashkin and Samarin, 2005). All this leads to the choice of  $\alpha$ -willemite as a sample for studying this type of luminescence in order to facilitate the interpretation of the kinetic and spectroscopic results of the experiment (Sarrigani and Amiri, 2019; Koshoridze *et al.*, 2017).

## 2. MATERIALS AND METHODS

The experiments were performed on a special high-vacuum installation, whose main components are given in (Shigalugov *et al.*, 2019). A dynamic vacuum of  $10^{-8}$  Torr in the sample chamber was maintained by two magnetic discharge pumps NMD-04-1 and NMD-016-1 (with a total pumping rate of 550 l/s). High purity gases were used: oxygen puriss. spec. (99.998%) and carbon monoxide CO puriss. (99.9%). The luminescence intensity was recorded using photoelectric devices: a photomultiplier (FEM-84-3), the signal from which was fed through a preamplifier (C7319 HAMAMATSU) to a computer recording module (ML-840 PowerLab 4/20 ADInstruments), or (at low light fluxes) to a photosensor module (H7468-01 HAMAMATSU) docked with an IBM PC (Zhou *et al.*, 2015). Luminescence spectra in the region of 350-1150 nm with a resolution of 1.5 nm were recorded by a scanning CCD array spectrograph (QE 65000 OCEAN OPTICS), also controlled by P.C. The temperature of a finely dispersed sample deposited from an alcohol suspension in the form of a thin layer ( $h \leq 100 \mu\text{m}$ ) on a heater substrate could be kept constant with an accuracy of  $\leq 1\%$  or quickly ( $< 10$  s) be changed using an electronic controller with the heater current (Delodovici *et al.*, 2017). Atomic oxygen with a flux density of up to  $j_{\text{O}} = 10^{14} \text{ cm}^{-2}\text{s}^{-1}$  was obtained by  $\text{O}_2$  thermolysis according to the procedure (Brennan, 1967) on a current-heated rhodium (Rh) ribbon measuring  $0.015 \times 1 \times 20$  mm.

A stream of CO molecules with a density of up to  $j_{\text{CO}} \sim 2 \cdot 10^{20} \text{ cm}^{-2}\text{s}^{-1}$  could be introduced into a sample of  $\text{Zn}_2\text{SiO}_4\text{:Mn}^{2+}$  pre-purified by long-time ( $\sim 2$  hours) high-temperature ( $T \sim 700$  K) heating in high vacuum ( $\sim 10^{-8}$  Torr).

Free O atoms obtained by dissociation of  $\text{O}_2$  on a ribbon (Rh) heated to 1800 K were previously adsorbed on the surface of  $\text{Zn}_2\text{SiO}_4\text{:Mn}^{2+}$  for 15 minutes from a mixture of  $\text{O}_2 + \text{O}$  at an oxygen pressure of 0.02 Torr for 13 minutes at a sample temperature constant for all experiments (400 K and 2 minutes) when setting the operating temperature (379 K, 400 K, 550 K) (Achatz *et al.*, 2010; Lemmerer, 2020). Then the reaction volume with the sample was pumped out for 10 minutes to a vacuum of  $3 \cdot 10^{-4}$  Torr and, further, a stream of CO was rapidly let in to a pressure of 0.5 Torr. The effect of triboluminescence, in this case, as shown by control experiments with nitrogen and inert gases, was negligible (Shang, 2017; Hsu *et al.*, 2017). During the filling process, the temperature of the sample was maintained by a constant high-speed electronic control system of the heater current. This made it possible to avoid side thermal effects (thermostimulated luminescence due to heat generation in the processes of adsorption and recombination, quenching of luminescence due to sample cooling during gas inlet, etc.) (Tanaka *et al.*, 2018; Bulychev, 2019; Bonacchi *et al.*, 2011; Hasobe, 2020). The flow of CO molecules onto the sample was supplied using a vacuum gate for a time  $\Delta t < 1$  s to 90% of 0.5 Torr and then remained unchanged during continuous pumping (curves 6 and 3 in Figure 1 and Figure 2).

## 3. RESULTS AND DISCUSSION:

Figure 1 shows the luminescence kinetics in the activator ( $\text{Mn}^{2+}$  ion) emission band  $\lambda_{\text{max}} = 527$  nm of the surface of  $\alpha$ -willemite  $\text{Zn}_{1.98}\text{Mn}_{0.02}\text{SiO}_4$  with pre-adsorbed O atoms that occurs when the stream of CO molecules is poured (Figure 1).

At the initial moment, the luminescence has the form of an adsorb luminescent (A.L.) flash (curves 1-5) (Accetta *et al.*, 2011; Sánchez-Carnerero *et al.*, 2015). At "low" sample temperatures ( $T = 300$  K, 370 K, curves 1, 2), after the flare, the luminescence monotonically decreases according to the law characteristic of AL (Grankin *et al.*, 1981), in this case, the Eley-Rideal shock recombination process (Equation 2).

In Equation 2, L is the symbol of the adsorption center on the surface;  $h\nu$  is the symbol of the emitted quantum of light. The luminescence decay kinetics is well described by the dependences of the form (Equation 3) at  $T = 300$  K (curve 1) (Equation 4) at  $T = 370$  K (curve

2). Here  $I$  is the luminescence intensity (relative units),  $t$  is time (seconds) (Babin *et al.*, 2015). At sample temperatures above 400 K, the second maximum begins to appear on the kinetic curve of luminescence decay, which is so pronounced at  $T = 625$  K that it significantly exceeds the initial flash of luminosity and light sum (Figure 1, curve 5). Further luminescence decay after the second maximum occurs by law (Equation 5) at  $T = 625$  K (Figure 1, curve 5) (which is characteristic of the second-order recombination process according to the Langmuir–Hinshelwood mechanism) (Zhu *et al.*, 2011; Kuznetsova and Rabinskiy, 2019). The second stage is possible only in the presence of adsorbed O-L atoms on the surface. Indeed, when CO is poured onto the same  $\text{Zn}_2\text{SiO}_4:\text{Mn}^{2+}$  sample, whose surface is filled only with molecular oxygen  $\text{O}_2\text{-L}$ , such luminescence curves with two maxima are not observed, and the intensity is almost two orders of magnitude lower than in the previous case (Figure 2).

In the opinion of the authors, the complex nature of the kinetic luminescence curves (Figure 1) may be due to the almost simultaneous occurrence of two types (stages) of the recombination process (Fahlman, 2018).

1. The stage of shock recombination (which is responsible for the initial flash) occurs non-activation. This is evidenced by the practical independence of the flash value on the sample temperature. The excitation of luminescence at this stage is most likely associated with the formation of electronically excited carbon dioxide molecules  $\text{CO}_2^e$  on the surface of solids (Bui and Dowell, 2020).

The formation of  $\text{CO}_2^e$  upon heterophasic oxidation of CO followed by radiative relaxation, is well known (Pravilov and Smirnova, 1981; Persson and Avouris, 1983). Figure 3 shows the dependence of the OC-O bond energy on the configuration coordinate (Pravilov and Smirnova, 1981). When the reagents come closer along the coordinate, the carbon dioxide molecule can enter the electronically excited states of  $\text{CO}_2^e$  ( $^3\text{B}_2$ ,  $^1\text{B}_2$ ).

It was shown in (Persson and Avouris, 1983) that even on the surface of metals, CO and  $\text{CO}_2$  retain their individuality, in particular, the local structure of electronic terms remains almost unchanged (Pham *et al.*, 2016; Gupta, 2018). On the surface of crystallophosphorus (semiconductors, dielectrics) having a much lower density of electronic states, the formation of electronically excited states along the adiabatic

interaction path of (Equation 6) is much more likely (Figure 3). A further adsorbed electron-excited  $\text{CO}_2^e\text{-L}$  molecule can radiatively relax to the ground state (Liu *et al.*, 2016). Luminescence in the blue and near-UV regions can be observed, slightly shifted to the short-wavelength region concerning homogeneous chemiluminescence with  $\lambda_{\text{max}} \sim 430$  nm (Pravilov and Smirnova, 1981). On the surface of the crystallophosphorus-insulator, non-radiative energy transfer becomes possible from  $\text{CO}_2^e(^3\text{B}_2)$  to the luminescence center ( $\text{Mn}^{2+}$  in our case) with the conservation of the total spin in the system (Equation 7) (Shigalugov *et al.*, 2000).

Since in the spectrum of this type of  $\text{Zn}_2\text{SiO}_4:\text{Mn}^{2+}$  luminescence (Figure 4) there is no (Equation 8) band with  $\sim 430$  nm, it can be assumed that the transfer of electron excitation energy from the  $\text{CO}_2^e(^3\text{B}_2)\text{-L}$  state to the surface and near-surface luminescence centers occurs at a rate significantly exceeding that of radiative relaxation ( $10^5\text{--}10^7$  s $^{-1}$ ) in the (Equation 9) donor.

2. The second stage (with activation), responsible for the high-temperature maximum on the kinetic curve  $I(t)$  (Figure 1, curves 3, 4 and 5), cannot be satisfactorily explained, like the source (Breysse *et al.*, 1978), only by surface recombination of adsorbed carbon monoxide molecules and oxygen atoms of the type (Equation 10).

This leads to a contradictory interpretation (process without and with activation) of different sections of the kinetic curves in Figure 1. The interpretation of this stage as the result of surface recombination of O-L atoms stimulated by the formed adsorption layer is most adequate (Liu and Qiu, 2015; Kumar and Srivastava, 2018). This layer consists, in this case, mainly of  $\text{CO}_2\text{-L}$  molecules, due to the intense oxidation of CO molecules flying from the gas phase (Dhbaibi *et al.*, 2018). As accumulation on the surface of  $\text{CO}_2\text{-L}$ , at an elevated sample temperature ( $T > 400$  K), the process of recombination of pre-adsorbed O-L atoms in the layer of  $\text{CO}_2\text{-L}$  begins (Equation 11).

An increase in temperature is necessary here to accelerate the surface diffusion of O-L atoms with the participation of  $\text{CO}_2\text{-L}$ . This model corresponds to the quadratic in  $t$  of the regions of acceleration and decay of luminescence (Tsuchiya *et al.*, 2019; Hasobe, 2020). This is consistent with experience (second maxima in curves 4 and 5 of Figure 1). The band gap (about 6 eV) of the  $\text{Zn}_2\text{SiO}_4:\text{Mn}^{2+}$  sample significantly

exceeds the binding energy (5.18 eV) in the O<sub>2</sub> molecule (Chang *et al.*, 1999). The (O-O) bond has a small anharmonicity (12.2 cm<sup>-1</sup>) and a small value of the vibrational quantum ( $\eta\omega_o < 0.2$  eV). For these conditions, the adiabatic mechanism of luminescence excitation at this stage is most probable (Styrov *et al.*, 1989). The resulting adsorption complexes in the neutral (O-L + O-L) and charged (O-L + O<sup>-</sup>-L) forms can adiabatically enter electronically excited states  $A^3\Sigma_u^+$ ,  $c^1\Sigma_u^-$  for the neutral form O<sub>2</sub><sup>e</sup>-L and  $^4\Sigma_u^-$ ,  $^2\Pi_u$ ,  $^2\Sigma_u^-$  for the charged form (O<sub>2</sub><sup>-</sup>)<sup>e</sup>-L (Rosen, 1970).

An effective non-radiative dipole transition with simultaneous energy transfer to luminescence centers located in the surface and near-surface regions is likely from the  $^2\Pi_u$  term (Crassous, 2020; Tadashi, 2020). For example, the relaxation of an (O<sub>2</sub><sup>-</sup>)<sup>e</sup>-L molecular ion to the ground state  $X^2\Pi_g^1$  from the  $^4\Sigma_u^-$ ,  $^2\Pi_u$ ,  $^2\Sigma_u^-$  states can occur in conjunction with the (Equation 12) transitions in the Mn<sup>2+</sup> ion in Zn<sub>2</sub>SiO<sub>4</sub>:Mn<sup>2+</sup> with the total spin remaining in the system. It is also possible to transfer energy to the centers of the activator and from neutral electronically excited (O<sub>2</sub>)<sup>e</sup>-L molecules (for example, upon transitions from (Equation 13) in the (O<sub>2</sub>)<sup>e</sup>-L molecule and (Equation 12) in the Mn<sup>2+</sup> ion.

#### 4. CONCLUSIONS:

Based on the experimental study carried out by spectral and kinetic methods, it was found that when a stream of carbon monoxide molecules is injected onto the surface of a solid – Zn<sub>2</sub>SiO<sub>4</sub>:Mn<sup>2+</sup> crystallophosphorus with pre-adsorbed atomic oxygen, a luminescent glow appears in the characteristic activator emission band of the Mn<sup>2+</sup> ion with a maximum near 527 nm, having a complex temporal nature. It was found that luminescence excitation proceeds in two main stages, somewhat time-shifted.

The first stage, which is responsible for the initial flare, proceeds non-activation according to the law characteristic of the shock recombination process. In this case, recombination of carbon monoxide molecules flying from the gas phase with oxygen atoms previously adsorbed on the surface of α-willemite appears according to the Eley–Rideal mechanism. In this case, the elementary mechanism of luminescence excitation includes the formation on the surface as a result of recombination of electronically excited carbon dioxide molecules, followed by non-radiative

transfer of excess energy to the Mn<sup>2+</sup> luminescence centers.

The second stage has a pronounced activation character and begins to manifest itself only at temperatures above 400 K. The kinetics of the decay of luminescence at this stage obeys the law characteristic of the second-order recombination reaction. In this case, the luminescence excitation model in the acts of surface recombination of pre-adsorbed oxygen atoms according to the Langmuir–Hinshelwood mechanism stimulated by the formed adsorption layer of carbon dioxide molecules is most adequate to experiment. The excitation micromechanism of this model involves the formation on the surface of α-willemite of electronically excited molecular ions and neutral oxygen molecules from adiabatically recombining oxygen atoms in charged and neutral forms. Further, effective non-radiative dipole transitions in oxygen ions and molecules with simultaneous energy transfer to the Mn<sup>2+</sup> luminescence centers located in the surface and near-surface regions while maintaining the full spin in the system become possible.

The proposed two-stage mechanism for the catalytic oxidation of carbon monoxide on the surface of α-willemite with pre-adsorbed atomic oxygen allows a consistent description of the luminescence observed in this case. This type of luminescence has the prospect of using for studying the mechanisms of catalytic oxidation of carbon monoxide, since using very sensitive informative optical methods allows revealing the details of the interaction of carbon monoxide with a crystalline catalyst containing atomic forms of oxygen in the surface layer, establishing the main stages of heterogeneous chemical reactions and studying patterns of atomic-molecular and electronic processes occurring on the surface.

**RESUMO**

A relevância do estudo se deve à deterioração da situação ambiental no mundo associada ao aumento da quantidade de resíduos plásticos, o que determina a viabilidade de desenvolvimento dos métodos para os envolver na reciclagem e produção futura de produtos plásticos. Este artigo tem como objetivo estudar os padrões de alterações nas propriedades físico-mecânicas e termofísicas de compósitos poliméricos à base de polipropileno secundário preenchido com casca de arroz na ausência de compatibilizadores. A principal abordagem para o estudo deste problema é a determinação do módulo de elasticidade na ruptura e flexão, resistência à tração na ruptura, deformação na ruptura e flexão, temperatura de flexão sob carga e temperatura de amolecimento Vicat, resistência de impacto de Charpy e Izod, parâmetros termofísicos dos compósitos poliméricos, o que possibilita considerar de forma abrangente as propriedades de compósitos biodegradáveis à base de polipropileno secundário na presença de casca de arroz. O artigo mostra que, com o aumento no teor de casca de arroz no compósito polimérico à base de polipropileno secundário, ocorre o aumento no módulo de elasticidade durante a ruptura e flexão. O enchimento de polipropileno com casca de arroz reduz um pouco a resistência à tração e reduz significativamente a elasticidade do polímero. O polipropileno secundário possui uma resistência ao impacto de Charpy superior à viscosidade de Izod. O enchimento do polímero com casca de arroz leva a diminuição da resistência ao impacto, de acordo com Charpy e com Izod. Além disso, com o conteúdo de carga superior a 5 partes de massa esses dois indicadores são quase idênticos. Nesse caso, há um ligeiro aumento na temperatura do início da decomposição térmica dos compósitos, o que determina sua estabilidade térmica durante o processamento. Foi revelado que compósitos poliméricos contendo 2-10 partes de massa de casca de arroz são caracterizados por um grau aumentado de cristalinidade da fase polimérica. Os materiais do artigo são de valor prático para o processamento de polímeros termoplásticos secundários, bem como para a criação de compósitos poliméricos biodegradáveis.

**ABSTRACT**

The relevance of the study is due to the deterioration of the environmental situation in the world associated with an increase of plastic waste, which determines the feasibility of developing methods for their involvement in recycling for the production of plastic products. Thereby, this article is aimed at studying the patterns of changes in the physical and mechanical and thermophysical properties of polymer composites based on recycled polypropylene filled with rice husk in the absence of compatibilizers. The leading approach to

the study of this problem is the determination of the modulus of elasticity in flexure, tensile strength at break, strain-to-failure, and bending strain, bending temperature under load and Vicat softening temperature, Charpy V-notch impact energy and Izod impact strength, as well as the thermophysical parameters of polymer composites. The article shows that with an increase in the content of rice husk in a polymer composite based on recycled polypropylene, an increase in the modulus of elasticity in flexure occurs. Filling polypropylene with rice husk slightly reduces the tensile strength and significantly reduces the elasticity of the polymer. Recycled polypropylene has a higher Charpy V-notch impact energy than Izod impact strength. Filling the polymer with rice husk leads to a decrease in impact strength according to both Charpy and Izod, and with a compound content of more than 5 phr, both of these indicators are almost identical. In this case, there is a slight increase in the onset temperature of the composites, which determines their thermal stability during processing. It was revealed that polymer composites containing 2-10 mass parts of rice husk are characterized by an increased degree of crystallinity of the polymer phase. The materials of the article are of practical value for the processing of recycled thermoplastic polymers, as well as the creation of biodegradable polymer composites.

**Keywords:** *failure resistance, elasticity, heat-distortion temperature, thermogravimetric analysis, differential scanning calorimetry.*

## АННОТАЦИЯ

Актуальность исследования обусловлена ухудшением экологической ситуации в мире, связанной с ростом количества пластиковых отходов, что определяет целесообразность разработки способов их вовлечения в повторную переработку с целью производства пластмассовых изделий. В этой связи большие перспективы связаны с разработкой биоразлагаемых композитов, одним из направлений, создания которых является наполнение синтетических полимеров компонентами растительного происхождения. В связи с этим, данная статья направлена на изучение закономерностей изменения физико-механических и теплофизических свойств полимерных композитов на основе вторичного полипропилена, наполненного рисовой шелухой в отсутствии совместителей. Ведущим подходом к исследованию данной проблемы является определение модуля упругости при разрыве и изгибе, прочности при разрыве, деформации при разрыве и изгибе, температуры изгиба под нагрузкой и температуры размягчения по Вика, ударной вязкости по Шарпи и Изоду, теплофизических параметров полимерных композитов (температура начала разложения, тепловые эффекты плавления и кристаллизации), что позволяет комплексно рассмотреть свойства биоразлагаемых композитов на основе вторичного полипропилена в присутствии рисовой шелухи. В статье показано, что с увеличением содержания рисовой шелухи в полимерном композите на основе вторичного полипропилена происходит увеличение модуля упругости при разрыве и изгибе. Наполнение полипропилена рисовой шелухой незначительно снижает прочность при разрыве и существенно уменьшает эластичность полимера. Вторичный полипропилен имеет более высокое значение ударной вязкости по Шарпи по сравнению с вязкостью по Изоду. Наполнение полимера рисовой шелухой приводит к снижению ударной вязкости как по Шарпи, так и по Изоду, причем при содержании наполнителя более 5 м.ч. оба этих показатели практически совпадают. Наполненные рисовой шелухой полимерные композиты обладают большей теплостойкостью. При этом наблюдается небольшое повышение температуры начала термического разложения композитов, что определяет их термическую устойчивость в процессе переработки. Выявлено, что полимерные композиты, содержащие 2-10 массовые части рисовой шелухи, характеризуются повышенной степенью кристалличности полимерной фазы. Материалы статьи представляют практическую ценность для переработки вторичных термопластичных полимеров, а также создания биоразлагаемых полимерных композитов.

**Ключевые слова:** *прочность, эластичность, теплостойкость, термогравиметрия, дифференциальная сканирующая калориметрия.*

## 1. INTRODUCTION

Currently, there is not a single application area where materials based on synthetic polymers are not used. Along with their obvious advantage over other materials related to the possibility of obtaining products with a wide range of operational properties, some practically decompose under the influence of environmental factors when released into nature. With the

increase in the production and consumption of synthetic polymers, the urgency of the problem of extracting these materials from waste and developing methods for their recycling increases. One of the most effective ways to solve this problem is to create polymer composites, the polymer matrix of which is recycled thermoplastic polymers in the presence of fillers, giving the material the required performance properties.

To date, a significant number of studies are devoted to the development of polymer composites based on thermoplastic polymers in the presence of vegetable compounds, which makes the material biodegradable (Yonghui *et al.*, 2015; Väisänen *et al.*, 2017; Yang, 2017; Erdogan and Huner, 2018; Orlov *et al.*, 2003; Krechetov *et al.*, 2018; Dipen *et al.*, 2019; Formalev *et al.*, 2018; Tarrés *et al.*, 2019). The use of a thermoplastic polymer makes it possible to repeatedly process such material by traditional methods (extrusion, injection molding), and a vegetable compound provides a reduction in the cost and weight of finished products, imparting the required performance characteristics and environmental friendliness of plastic products (Kasakova *et al.*, 2018; Usenbekov *et al.*, 2014).

One of the promising vegetable compounds for creating polymer composites based on thermoplastic polymers is rice husk (Arjmandi *et al.*, 2015; Chen *et al.*, 2016; Kenechi *et al.*, 2016; Arjmandi *et al.*, 2017; Dasa *et al.*, 2019). Prospects for the use of rice husk to obtain polymer composites are due to its low water absorption (Chen *et al.*, 2016; Lomakin *et al.*, 2018) and increased thermal stability (Hidalgo-Salazar and Salinas, 2019) due to the high content of silicon oxide in the compound (Cardona-Urbe *et al.*, 2018). Due to the thermodynamic incompatibility of rice husks and polymer matrices, various compatibilizers are traditionally used to create polymer composites with the required physical and mechanical properties (Arjmandi *et al.*, 2015; Majeed *et al.*, 2017; Formalev *et al.*, 2016; Lomakin *et al.*, 2017; Raghu *et al.*, 2018; Orji and McDonald, 2020), which increases the cost of finished plastic products. The purpose of this work was to study the patterns of change in the physical and mechanical and thermophysical properties of polymer composites based on recycled polypropylene filled with rice husk in the absence of compatibilizers.

## 2. MATERIALS AND METHODS

Recycled polypropylene was used in the work as a polymeric matrix in the form of crushed material from substandard plastic products produced by injection molding. Rice husk was used to fill the recycled polypropylene (composition: cellulose 40-45%, lignin 20-25%, hemicellulose 15-17%, mineral substances 18-22%) with a particle diameter of not more than 0.4 mm. The ratio of parts by mass (phr) of the compound was calculated on 100 mass parts of the polymer (Binoj *et al.*, 2016; Danilova-Tretiak

*et al.*, 2017). The test samples were obtained by injection molding on a Babyplast 6/10P injection-molding machine at a temperature in the zones of 225 °C, 235 °C, 220 °C, an injection pressure of 65 bar, an injection speed of 30%, and a clamping force of 35 bar. The temperature of the supply of cooling water to the mold was 12 °C, and the dwelling time was 10 s.

The physical and mechanical properties of the test samples at the break and cross breaking were determined according to GOST 11262-2017 and GOST 4648-2014, respectively, on a Shimadzu AGS-X universal testing machine at a temperature of 23 °C, a moving, gripping speed of 1 mm/min when determining the module of elasticity and 5 mm/min when determining other characteristics (GOST 11262-2017; GOST 4648-2014). Uniaxial tensile mechanical tests were performed on prototypes with dimensions according to GOST 11262-2017 (type 5). The tests were carried out on a universal testing machine AGS-X10kN (Shimadzu, Japan) at a temperature of 23±2 °C and a moving capture speed of 1 mm/min to determine the modulus of elasticity (GOST 9550-81) and a speed of 5 mm/min to determine other characteristics. Mechanical tests for static bending were performed on samples with sizes recommended according to GOST 4648-2014. The tests were carried out on a universal testing machine AGS-X10kN (Shimadzu, Japan) at a temperature of 23±2 °C and a traverse speed of 1 mm/min to determine the modulus of elasticity (GOST 9550-81) and a speed of 5 mm/min to determine other characteristics. Charpy V-notch impact energy and Izod impact strength (notched and unnotched) were determined according to GOST 4647-2015 and GOST 19019-2017, respectively, on a GT-7045-HMH pendulum (GOST 4647-2015; GOST 19019-2017). The Charpy impact toughness (with notch and without notch) was determined according to GOST 4647-2015 on the pendulum testing machine GT-7045-HMH (Taiwan, Gotech Testing Machines). The summary of test method in which a sample lying on two supports is subjected to a pendulum impact at a constant speed (when struck "flat" or "with edge"), the impact line being located in the middle between the supports and directly opposite the notch of the notched prototypes. The impact is applied to the surface of the prototype opposite the notch.

The Izod impact toughness of prototypes (with and without notches) was determined according to GOST 19109-2017 on the GT-7045-HMH pendulum testing machine (Taiwan,

Gotech Testing Machines). The summary of test method consists in destruction of the cantilevered sample by the impact of the pendulum at a certain distance from the fixing point, in the case of a notched sample, from the midline of the notch. The bending temperature under load (1.8 MPa) and the Vicat softening temperature (50 N) were determined according to GOST 32657-2014 and GOST 15088-2014, respectively, on an HV-3000-P3 device. Bending temperature under load. The prototype is subjected to three-point bending under the action of a constant load from the side of the main (preferably) or lateral plane of the prototype to obtain bending stress. The temperature is raised at a uniform speed and its value is measured at which a standard deflection occurs, corresponding to the established increase in stress during bending.

The softening temperature of thermoplastics according to Vicat. The summary of the method is to determine the temperature at which a standard indenter with a flat bottom surface under the influence of load penetrates into the test prototype, heated at a constant speed, to a depth of 1 mm. Indenter is located perpendicularly to the surface of the prototype (GOST 32657-2014; GOST 15088-2014).

The methods of thermogravimetric analysis (TGA) and differential scanning calorimetry were used (DSC) in order to analyze the thermophysical parameters of polymer composites. Studies of polymer samples were carried out under the following conditions: TGA – temperature range 25-600 °C, dynamic mode – the heating rate of 5 deg/min, medium – air, TGA-DSC device; DSC – temperature range – 40-200 °C, dynamic mode – heating/cooling rate of 10 deg/min, medium – air, DSC-1 device. These methods allow to determine the following thermophysical indicators:  $T_c$  is the onset temperature;  $T_1$ ,  $T_5$  is the temperature corresponding to a decrease in the mass of the sample by 1 and 5%, respectively;  $T_{max}$  is the temperature corresponding to the maximum rate of mass loss at TGA;  $T_{ml}$ ,  $T_{cr}$  is the melting and crystallization temperature;  $\Delta H_{ml}$ ,  $\Delta H_{cr}$  is the thermal effect of melting and crystallization.

### 3. RESULTS AND DISCUSSION:

The results showed that the modulus of elasticity both at the break and cross breaking increases as the content of the vegetable compound in the polymer composite increases (Table 1). The modulus of elasticity at the break

for a recycled polypropylene filled with rice husk in a volume of 30 phr increases by 1.36 times, and the modulus of elasticity in flexure – by 1.47 times in comparison with the initial polymer. In light of the fact that the modulus of elasticity correlates with the ability of a polymer sample to deform elastically under the influence of an external load, the filling of polypropylene with rice husks determines the possibility of obtaining more rigid plastic products (Das *et al.*, 2018; Rutkowska *et al.*, 2018).

It should be noted that plastic products made from polymer composites in the presence of a vegetable compound are more resistant to elastic deflections. This is confirmed by minor changes in the breaking elongation for polymers with varying degrees of filling of rice husk (Table 1). Filling recycled polypropylene with even a small amount of rice husk leads to a significant decrease in the tensile elasticity of the material. Addition 2 phr of rice husk reduces the strain at break from 588% for recycled polypropylene without compound to 26% for the composite (Table 1).

A further increase in the content of rice husk successively reduces the breaking elongation to 5% for a composite with 30 phr of the compound (Saigal and Pochanard, 2019; Stolin *et al.*, 2020). Compared to recycled polypropylene, a polymer composite has a lower tensile strength at break. With an increase in the content of rice husk up to 15 phr, the strength decreases almost linearly from 25.5 MPa to 21.3 MPa, and a further two-fold increase in the compound concentration determines a decrease in tensile strength by only 2.3% (Table 1).

Along with a decrease in the cross-breaking strength for filled composites, the resistance of plastics to dynamic impact worsens, which manifests itself in a corresponding change in impact value (Figure 1). Recycled polypropylene has a relatively high Charpy V-notch impact energy (rib impact) of 40.7 kJ/m<sup>2</sup>. The Izod impact strength for this polymer is 26.1 kJ/m<sup>2</sup>. Filling the polymer with rice husk leads to a decrease in impact strength according to both Charpy and Izod, and with a compound content of more than 5 phr, both of these indicators are almost identical (Bisht and Gope, 2015; Sutar *et al.*, 2018). Applying a notch simulating the presence of a mechanical defect in a plastic product significantly reduces the impact strength, according to both Charpy and Izod (Figure 1). For notched specimens, Izod impact strength is higher than Charpy V-notch impact energy for all considered polymer

composites. Compared with recycled polypropylene, an increase in impact value is observed with the addition of 2 phr of rice husks, which can be used to obtain plastic products more resistant to external dynamic effects (Figure 1).

The use of rice husks can increase the heat-distortion temperature of plastic products based on recycled polypropylene (Figure 2). Introduction to the polymer 2 phr of compound leads to a slight decrease in bending temperature under load, the value of which with a further increase in the degree of filling of the composite increases from 57.4 °C for recycled polypropylene to 65.5 °C for a polymeric composition filled with 30 phr of rice husk. The Vicat softening temperature, in this case, rises from 75 °C for polypropylene to 84.6 °C for a composite with 30 phr of rice husk (Figure 2).

Rice husk used as a compound has a low value for the onset temperature  $T_H$ ; a decrease in the mass of the product begins even at temperatures above 26 °C. A noticeable (by ~ 4%) decrease in the mass of the sample upon heating to 100 °C indicates the presence in the rice husk of a sufficiently large number of volatile components (probably moisture or solvent).

A further increase in temperature is accompanied by a gradual decrease in the mass of the product. The decomposition of rice husk on the differential thermal analysis (DTA) curve corresponds to two main temperature ranges (Table 2). At the stage of the temperature range of 170-358 °C with a maximum  $T_{max,1}$  at 288°C, a 55% decrease in product mass is observed. At the stage of the temperature range of 358-470 °C with a maximum  $T_{max,2}$ =403°C, there is a decrease in the mass of the product by 23%, which, apparently, corresponds to the burnup of the resulting coke residue (Table 2).

It should be noted that the temperatures ( $T_{max,1}$  and  $T_{max,2}$ ) on the DTA curve, corresponding to the maximum decomposition rate of rice husk, are shifted to the lower values relative to similar parameters for recycled polypropylene (Table 2). The value of the residue (27.9%) after heating the rice husk to a temperature of 400 °C is noticeably larger compared to the same parameter for recycled polypropylene (Gowda *et al.*, 2018; Mohapatra, 2018). This indicates that the decomposition of rice husk, the main component of which is cellulose, in this temperature range occurs to a lesser extent (with a lower rate), compared with polypropylene. A relatively large amount of

residue (17.2%) after heating the rice husk to 600 °C indicates the presence of thermally stable silicon oxide in the product (Cardona-Urbe *et al.*, 2018; Dorca *et al.*, 2019). Composites based on recycled polypropylene filled with various amounts of rice husk have rather close values of the onset temperature  $T_c$  218-231°C (Table 2). It is noteworthy that the indicated  $T_c$  values are higher than that of rice husks and recycled polypropylene (Table 2).

An increase in the content of the vegetable compound from 2 to 30 phr does not lead to a significant change in the parameter  $T_c$  of the polymer composite, the values of parameters  $T_1$  (242-252 °C) and  $T_5$  (262-267 °C) are also in a rather narrow range (Table 2). It is seen that thermal-oxidative breakdown of polymer composites proceeds in two stages: the main decomposition (by 85-94%) occurs in the temperature range from  $T_c$  to 380-400°C; the temperature range of 400-600 °C corresponds to a decrease in the mass of the sample by ~ 3-7% (Table 2). With an increase in the content of vegetable compound in the polymer composite from 5 to 30%, the maximum temperature on the DTA curve shifts to a lower range:  $T_{max,1}$  from 356 to 327 °C and  $T_{max,2}$  from 421 to 417 °C. The observed changes are due to the influence of rice husk, whose decomposition corresponds to lower temperatures, compared with the decomposition of polypropylene (Gadzama *et al.*, 2020; Ghosh and Dwivedi, 2020). With an increase in the filler content in the compound from 2 to 30 phr the proportion of the product remaining after heating the sample to 400 °C (from 6.5 to 11.4%) and 600 °C (3.2% to 5.9%) increases, and the dependence of the residue on the compound content is linear (Nyior and Mgbeahuru, 2018; Pandey, 2020).

When conducting DSC analysis, it was found that filling the recycled polypropylene with rice husk in the range of 2-30 phr does not lead to a noticeable change in the melting ( $T_{mi}$ =166.2-166.7°C) and crystallization ( $T_{cr}$ =116.2-117.8°C) temperatures of composites whose values are close to the corresponding indicators of recycled polypropylene (Table 3). At the same time, the compound has a significant effect on the enthalpy (thermal effect) of the melting and crystallization of the polymer phase. The introduction of already a small amount (2 phr) of rice husk into the polymer leads to a noticeable (12 J/g) increase in the melting enthalpy of the composite compared to an unfilled polymer, and the crystallization enthalpy also increases, but to a lesser extent (Table 3). It should be noted that

$\Delta H_{ml}$  and  $\Delta H_{cr}$  of composites containing 2-10 phr of rice husk is higher than that of the initial polypropylene. It can be assumed that the compound particles can play the role of crystallization nuclei, which contributes to an increase in the degree of crystallinity of the polymer phase and an increase in the heat of fusion and crystallization. With a further increase in the compound content in the polymer composite, the values of the enthalpy of melting and crystallization naturally decrease. When changing the content of rice husks in the composite from 2 to 30 phr the values of  $\Delta H_{ml}$  and  $\Delta H_{cr}$  decrease, respectively, by 1.47 and 1.36 times (Table 3), which, obviously, is associated with a decrease in the amount of the polymer phase in the composite.

#### 4. CONCLUSIONS:

With an increase in the content of rice husk in a polymer composite based on recycled polypropylene, an increase in the modulus of elasticity in flexure occurs, and plastic products made from polymer composites with the compound are more resistant to flexural deflections. Filling polypropylene with rice husk slightly reduces the tensile strength at break and significantly reduces the elasticity of the polymer. Recycled polypropylene has a higher Charpy V-notch impact energy than Izod impact strength. Filling the polymer with rice husk leads to a decrease in impact strength according to both Charpy and Izod, and with a compound content of more than 5 phr, both of these indicators are almost identical. Applying a notch simulating the presence of a mechanical defect in a plastic product significantly reduces the impact strength, according to both Charpy and Izod.

For notched specimens, Izod impact strength is higher than Charpy V-notch impact energy for all considered polymer composites. Polymer composites filled with rice husks have a greater heat-distortion temperature, characterized by bending temperature under load and Vicat softening temperature. In this case, there is a slight increase in the onset temperature of the composites, which determines their thermal stability during processing. It was revealed that polymer composites containing 2-10 phr of rice husks are characterized by an increased degree of crystallinity of the polymer phase.

Compared with pure polypropylene, rice husk based composites have a higher modulus of elasticity at break and bending. Polymer

composites are more resistant to high temperature, which is manifested in high values of bending temperature under load, Vicat softening and the beginning of decomposition. Filling polypropylene with rice husk leads to a decrease in strength and breaking elongation, decrease of Charpy and Izod impact toughness.

## **RESUMO**

O objetivo desta pesquisa é desenvolver produtos funcionais a partir de subprodutos biomodificados de baixa qualidade e resíduos usando consórcios de microrganismos. Para criar condições para uma dieta equilibrada e melhorar a saúde da população, foi proposta a técnica de utilização de métodos biotecnológicos direcionados à atração de recursos não tradicionais. O objetivo do estudo foram subprodutos secundários da carne e resíduos da indústria de processamento de carne. Os produtos cárneos e resíduos foram processados com bactérias lácticas como *Lactobacillus bulgaricus*, *Bifidumbacterium siccum* e *Staphylococcus carnosus*. As bactérias do ácido láctico foram cultivadas passo a passo em diferentes combinações: *Staphylococcus carnosus* e *Lactobacillus bulgaricus*; *Bifidumbacterium siccum* e *Staphylococcus carnosus*; *Lactobacillus bulgaricus* e *Bifidumbacterium siccum*. Mudanças na atividade de crescimento das espécies selecionadas de bactérias lácticas em várias combinações foram realizadas em vários meios nutricionais. Ao cultivar as cepas estudadas em um meio de agar de carne e peptona, sua identificação completa foi realizada. A etapa final foi a análise da qualidade dos objetos reais: carne de cavalo, flank e tecido muscular padrão da carne bovina. A dinâmica das mudanças nos indicadores de propriedades funcionais, tecnológicas e organolépticas da carne provou um efeito positivo do uso de bactérias do ácido láctico. As raças desenvolvidas demonstraram a capacidade de suprimir ativamente a microflora prejudicial nos produtos à base de carne. Além disso, amoleceram a carne secundária para processamento e provaram positivamente melhorar as características organolépticas do produto acabado. O processamento de recursos secundários de subprodutos e resíduos permitirá o uso mais econômico e racional da reserva alimentar mais essencial de carne e derivados, contendo colágeno. A cobertura insuficiente desta questão sobre o uso de uma cepa combinada dessas espécies de microrganismos para a biomodificação de subprodutos secundários contendo colágeno e resíduos na indústria de carne indica a relevância do tópico escolhido.

**Palavras-chave:** biomodificação; biotecnologia; subprodutos e resíduos contendo colágeno, bactérias do ácido láctico.

## **ABSTRACT**

This research purpose is to develop functional products from biomodified low-grade by-products and waste using microorganism consortia. To create conditions for a balanced diet and improve the health of the population, the technique of using biotechnological methods directed at attracting non-traditional resources was proposed. The object of the study was secondary meat by-products and waste from the meat processing industry. The meat products and waste were processed with such lactic-acid bacteria as *Lactobacillus bulgaricus*, *Bifidumbacterium siccum*, and *Staphylococcus carnosus*. Lactic-acid bacteria were cultured step-

by-step in different combinations: *Staphylococcus carnosus* and *Lactobacillus bulgaricus*; *Bifidumbacterium siccum* and *Staphylococcus carnosus*; *Lactobacillus bulgaricus* and *Bifidumbacterium siccum*. Changes in the growth activity of selected species of lactic-acid bacteria in various combinations were carried out in various nutrient media. When growing the studied strains in a medium of meat-and-peptone agar, their complete identification was carried out. The final stage was the analysis of the quality of real objects: horse meat, flank, and standard beef muscle tissue. The dynamics of changes in indicators of functional and technological and organoleptic meat properties proved a positive effect from the use of lactic acid bacteria. Developed races have shown the ability to suppress harmful microflora in meat products actively. Moreover, they softened the secondary meat for processing and positively proved to improve the finished product's organoleptic characteristics. Processing of secondary resources of by-products and waste will allow more economical and rational use of the most essential collagen-containing food reserve of meat and meat products. The insufficient coverage of this issue on the use of a combined strain of these species of microorganisms for the biomodification of secondary collagen-containing by-products and waste in the meat industry indicates the relevance of the chosen topic.

**Keywords:** biomodification; biotechnology; collagen-containing by-products and waste, lactic-acid bacteria.

## АННОТАЦИЯ

Цель исследования - разработка функциональных продуктов из биомодифицированного низкосортного сырья с использованием консорциумов микроорганизмов. Для создания условий для рационального питания и улучшения здоровья населения нами предлагается использовать прием, направленный на привлечение нетрадиционных ресурсов с использованием методов биотехнологии. В качестве объекта исследования служило вторичное мясное сырьё мясоперерабатывающей промышленности: мяса конины, пашины и говяжьей мышечной ткани второго сорта. Объектом исследования выступили *Lactobacillus bulgaricus*, *Bifidumbacterium siccum*, *Staphylococcus carnosus*. Культивация молочнокислых бактерий осуществлялась поэтапно в разных сочетаниях: *Staphylococcus carnosus* и *Lactobacillus bulgaricus*; *Bifidumbacterium siccum* и *Staphylococcus carnosus*; *Lactobacillus bulgaricus* и *Bifidumbacterium siccum*. Активность роста молочнокислых бактерий изучали на различных питательных средах (мясопептонный агар и мясопептонный желатин). Для этого суспензию культур культивировали в стерильных условиях на питательных средах, являющейся оптимальной для их роста. В процессе выращивания исследуемых штаммов на среде с применением мясопептонного агара была проведена полная их идентификация. Для оценки скорости роста тестируемых штаммов использовали специфические питательные среды. На завершающем этапе был проведен анализ качества реальных объектов: мяса конины, пашины и говяжьей мышечной ткани второго сорта по показателям функционально-технологических свойств и был установлен положительный эффект от их применения, поскольку выведенные расы проявили способность активно подавлять вредную микрофлору, развивающуюся в мясных продуктах. Кроме того, переработки вторичных сырьевых ресурсов позволит более экономно и рационально использовать важнейшие пищевой коллагенсодержащий резерв мяса и мясных продуктов. Недостаточная освещенность данного вопроса по применению комбинированного штамма данных видов микроорганизмов для биомодификации вторичного коллагенсодержащее сырьё мясной промышленности свидетельствует об актуальности выбранной темы.

**Ключевые слова:** биомодификация, биотехнология, коллагенсодержащее и вторичное сырьё, молочнокислые бактерии.

## 1. INTRODUCTION:

Currently, it is possible to produce new types of meat by-products and waste for general, special and therapeutic purposes, improve methods of enzymatic processing of meat raw materials in order to improve its functional and technological properties, produce food and feed hydrolysates, synthesize flavorings, dyes, biologically active substances, to synthesize feed proteins, and in the future, proteins for human nutrition based on biotechnology in the meat industry (Antipova, 2001; Antipova *et al.*, 2011; Armuzzi *et al.*, 2001; Audenaert *et al.*, 2010;

Dušková *et al.*, 2016; Wanget *et al.*, 2013).

Products containing consortia of lactic acid and bifidobacteria play an essential role in the nutrition of people, especially children, the elderly, and patients. First of all, the dietary properties of such products are in that they improve metabolism, stimulate the secretion of gastric juice, and stimulate the appetite. Being in food products and making up most of the microflora of the human gastrointestinal tract, taking root in the intestines, they actively suppress putrefactive microflora and lead to inhibition of putrefactive processes and stop the formation of toxic decay products of proteins

entering the human blood. Along with this, microorganisms are active producers of useful substances that are capable of transforming natural or chemically synthesized compounds into substances valuable to humans. Their sources are inexpensive and practically inexhaustible. Many of them must synthesize heterogeneous systems of enzymes that convert proteins. This suggests the effectiveness of their use for biotransformation of protein systems of low-grade meat by-products and waste by microbial fermentation with the selection of specific consortia (Armuzzi *et al.*, 2001; Dušková *et al.*, 2016).

Some American factories use a pure culture of *Pediococcus cerevisiae* to manufacture summer types of sausages such as cervelat and salami. When sugar is added, it promotes the formation of lactic acid and gives the sausages a specific, characteristic flavor. When using this culture, the sausage manufacturing process is reduced to 48 hours while usually it is kept at (7-10) °C for 3-7 days, and then smoked at (27-44) °C for 2 -3 days (Antipova *et al.*, 2016; Gavrilova *et al.*, 2019).

From the point of view of aroma formation, the starting culture of *Moraxella phenylpyruvica*, the Danish Meat Institute's development product, is of interest. This is a psychrophilic culture – an optional anaerobic which allows it to develop in the thickness of the product actively and, as studies have shown, to produce substances that are precursors of aroma. Along with traditional bacteria, such as *Lactobacillus* and *Pediococcus*, American technologists include *Micrococcus* in the starter cultures, which can reduce nitrates to nitrites while improving the taste and color of finished sausages (de Souza Barbosa *et al.*, 2015).

In Italy, strains of *Micrococcus* sp., *Lactobacillus bulgaricus* were tested to study the organoleptic properties of dry sausages as starter cultures. A new bacterial culture, *Lactobacillus pentosus*, was tested in the laboratory of R. Muller (Germany) in the production of dry sausages. Several other cultures were used to compare the technological effect: *Petrostreptococcus parvulus*, *Lactobacillus bulgaricus*, *Pediococcus acidilactici*, and their combination with *Streptococcus carnosus* MIII. In all variants of testing microorganisms, the best results were obtained with *Lactobacillus pentosus*. The effect was expressed in a rapid decrease in pH by obtaining sausages of attractive color, soft-sour taste, and pronounced meat aroma (Cocolin *et al.*, 2009).

In the meat industry, biotechnology is used in raw meat processing with enzyme preparations to soften its stiffness and increase the nutritional value, making it possible to use low-grade raw materials to produce high-quality meat products. Experts consider the enzymatic method of softening meat one of the most effective (de Souza Barbosa *et al.*, 2015; Doulgeraki *et al.*, 2012; Ilina *et al.*, 2017).

The All-Russian Scientific Research Institute of the Meat Industry (VNIIMPom) conducted studies on the use of microbial preparations for the complete separation of meat from bones after deboning and sending the resulting mass to prepare meat pastes, emulsions, hydrolysates (Antipova and Uspenskaj, 2016; Gavrilova *et al.*, 2019). Studies were conducted at the same institute on the use of brewer yeast biomass as polyezyme preparations for the hydrolysis of blood proteins in slaughtered animals, resulting in an increase in the biological efficiency of blood proteins by 10-30%. Hydrolyzed by yeast, blood is recommended to be used as an additive to meat products to give them a good taste.

One of the biotechnology applications to obtain additional protein sources is the use of unicellular bacteria, fungi, yeast, and algae for the enrichment of meat products. As shown by studies conducted by institutes of the Russian Academy of Sciences, the Russian Academy of Medical Sciences (Antipova *et al.*, 2016), VNIIMPom, this method allows getting diet meat products. The Kemerovo Technological Institute of the Food Industry researched the use of cooked sausages in technology to replace soy protein brewing yeast, which is the secondary raw material for brewing (Antipova *et al.*, 2015; Gavrilova *et al.*, 2019). One of the new biotechnology areas in sausage production is the improvement of the taste, color, and aroma of meat products of high-quality flavorings, various flavoring substances of microbial origin (Armuzzi *et al.*, 2001; Cocolin *et al.*, 2009). Another promising area of application of the principles of biotechnology is the fortification of meat products and the solution of issues related to the development of this problem. Scientists of VNIIMP, KemTIIP, and others are enriching foods with vitamins (Antipova *et al.*, 2011; Audenaert *et al.*, 2010). For example, KemTIIP experts in collaboration with scientists of the Institute of Nutrition RAMS developed a technology to enrich meat products with vitamins C, B1, B2, and PP, which allows saving almost half of their activity (Gabitov *et al.*, 2019; Wang *et al.*, 2013). In the

neighboring countries, research is also being carried out to introduce biotechnological processes in the meat industry, which in their direction coincide with the Russian ones. In Belarus, technology has been developed for two bacterial preparations: Acidolact and Lactobact (liquid and dry) used as part of multi-component brine for extrusion of beef products (Bonomo *et al.*, 2008).

In Kazakhstan, the Semipalatinsk Institute of Meat and Dairy Industry created a composition for producing a protein fortifier used in sausage production (de Souza Barbosa *et al.*, 2015; Dušková *et al.*, 2016). In the Almaty branch of the Dzhambul Technological Institute of Light and Food Industries, a biological product of decolorized sedimentary yeast used to enrich sausages was obtained (Gabitov *et al.*, 2018; Konashova *et al.*, 2018).

Much attention is paid to the application of biotechnological techniques in the meat industry in far abroad countries. The directions there are mainly focused on improving the quality of meat products, intensifying production, creating new types of products based on meat balanced in chemical composition, environmentally friendly directed actions, including therapeutic and prophylactic purposes (Buchanan and Gibbons, 1994).

The main areas of application of biotechnology in sausage production are the use of biomass of microorganisms and preparations based on them as a substitute for meat raw materials, a source of vitamins, micro and macro elements for the production of sausages, increased nutritional value, producer of enzymes, amino acids, flavorings, and colorings in order to improve technological processes, create fundamentally new technologies, improve genetic safety, lengthen the shelf life, improve the taste, aroma and other values of product quality; the use of immobilized enzymes, the advantage of which is the possibility of their repeated use, the increased stability, and duration of enzymatic activity, the possibility of use in continuous technological processes, the relatively short exposure time to the substrate, the possibility of creating multi-enzyme systems that are highly effective and, finally, in hygienic safety (Holko *et al.*, 2013; Nesterenko *et al.*, 2018).

In recent years, in Romania, Italy, Bulgaria, Switzerland, and other countries, the use of molds for producing smoked sausages has increased. It was noted that sausages with a dense coating of white or gray mold on the shell

are better than without it. Swedish scientists have developed a method for the production of minced meat with improved properties. According to this method, the meat is treated with a heat-sensitive proteinase (Gizatova *et al.*, 2014). In the UK, it is recommended to use two groups of enzymes in the food industry. The first group includes enzymes of animal and vegetable origin, and the second – enzymes of microbial origin – temporarily used (Ammor and Mayo, 2007). A new direction is being planned in the fermentation of meat. For improving the quality of meat, enzyme preparations (papain) are introduced into the blood of slaughtered animals immediately before slaughter, which significantly improves the meat grade. A mixture of papain and bromelin can be used for salting beef (Casquete *et al.*, 2011; Gizatov and Gizatova, 2015; Nesterenko *et al.*, 2016; Rakhimov *et al.*, 2018).

The problem of obtaining proteins from non-traditional types of raw materials (bacteria, fungi, yeast) to use them in meat products is intensively worked in the USA, Great Britain, Italy (Iliina *et al.*, 2017; Juntunen *et al.*, 2001; Knolet *et al.*, 2001). In the USA, dietary sausages are being produced with the protein product Muco protein, which is made from a filamentous fungus that can double its volume in 2.5 hours (Dušková *et al.*, 2015). In Italy, yeast extract is used in the production of cooked, liveried, semi-smoked, and cooked smoked sausages. In Yugoslavia, studies are being conducted on the use of brewer yeast preparations as substitutes for sodium caseinate and soy isolate in meat products (Argyriet *et al.*, 2015).

For the production of dry sausages in the hot season, foreign enterprises of Germany and Italy use pure culture *Pediococcus cerevisiae* as part of the recipe. According to the technology for the preparation of sausages, a certain amount of sugar is introduced, favorably affecting the formation of a taste and aroma specific to this type of product. The introduction of *Pediococcus cerevisiae* reduces the production time of sausages to 48 hours against 3-7 days required for precipitation and 2-3 days for smoking (Sydykova *et al.*, 2019; Vladimirovna and Borisovich, 2016; Zinina and Rebezov, 2016).

From the point of view of aroma formation, the Danish Meat Institute's development, the *Moraxella phenylpyruvica* culture, is of interest. It is a psychrophilic culture – an optional anaerobic that allows growing exponentially in the thickness of the product and, as studies have shown, producing substances that are precursors of aroma. Along with native bacteria, such as

Lactobacillus and Pediococcus, American technologists include Micrococcus in starter cultures, which can restore nitrates to nitrites, improving the taste and color of finished sausages (Karam *et al.*, 2013). In Italy, when studying sensory properties, strains of *Micrococcus* sp., *Lactobacillus bulgaricus* were used as test starter cultures (Adams and Mitchell, 2002). During the development of uncooked smoked sausages, a new bacterial culture of *Lactobacillus pentosus* was tested in the research laboratory of R. Muller (Germany). Many other cultures were used to compare the effect of the technology: *Petrostreptococcus parvulus*, *Lactobacillus bulgaricus*, *Pediococcus acidilactici*, as well as their combination with *Streptococcus carnosus*. Of all the microorganisms tested, the best results were obtained with *Lactobacillus pentosus*. There was a rapid decrease in pH, which resulted in an attractive color, soft-sour taste, and a pronounced meat aroma of the obtained sausages (Martynov *et al.*, 2018). The aim of this study is to combine the above microorganism strains to soften the secondary collagen-containing by-products and waste of the meat industry.

## 2. MATERIALS AND METHODS:

Meat and meat products are an excellent source for the development of lactic acid bacteria. They get everything they need from meat: sources of carbon, nitrogen, vitamins, and mineral salts. The meat's pH and humidity also contribute to growth (Martynov *et al.*, 2018). The objects of study were: – fresh and frozen beef of the highest, first and second grades according to GOST 779 (Ilin *et al.*, 2017), model minced meat, sausages obtained on its basis with and without biotechnological processing methods; – sturdy and low-grade collagen-containing raw materials of the meat industry (beef flank, beef veins, horse meat). Beef and horsemeat samples for research were taken under GOST R 51447, GOST 9792 (Antipova, 2001; Dušková *et al.*, 2015; Kno *et al.*, 2001) after which they made a combined sample and, denoting the name of the sample, were wrapped in parchment. Processing model minced meat with an ingredient such as salt does not adversely affect the growth of lactic acid bacteria, as most strains can withstand salt concentration. The temperature has a definite effect on the salt tolerance of lactic acid bacteria. At optimal growth of temperatures, they resist a salt concentration of up to 12%. Certain doses of

salt even stimulate growth (Martynov *et al.*, 2018).

An essential parameter of the starter culture quality is the suitability of the product, which should be confirmed in the study. When compiling a consortium of crops, it is necessary to take into account the characteristics of the product being produced, the temperature regime of the product (Bulat *et al.*, 2012; Ivanov *et al.*, 2018; Konashova *et al.*, 2018). The temperature should be maintained at an optimum level without violating the boundaries. The most commonly used thermophilic cultures are *Str. thermophilus*, *lac. bulgaricus*, *Las. lactis*, *Lbm. helveticus* and *Lbm. acidophilus*. In a broader sense, the *Bifidus* group (the *Bifidobacterium* *Atinomyetaceae* family) can be assigned to this group of microorganisms (Bulat *et al.*, 2012).

Like mesophilic organisms, thermophilic biomass culture has antimicrobial properties due to the inhibition of nutrients, low pH, the formation of antibiotics, and other factors that have a deterrent effect. When choosing, a number of requirements were taken into account, including those that are not harmful to the human body, a high growth rate, and, therefore, cell reproduction.

During the experiment, the growth activity of lactic acid bacteria on various nutrient media (meat peptone agar and meat peptone gelatin) was studied in order to select strains with specific properties and create consortia based on them taking into account physiological and biochemical characteristics. The suspension of cultures was cultivated under sterile conditions in a box, introduced into nutrient media in meat peptone agar and meat peptone gelatin, and grown in a thermostat at an optimum temperature of + 28°C for growth.

The next stage of our research was to study the growth of selected strains of lactic acid bacteria on specific nutrient media: gelatin and collagen gels, which were prepared by hydration of gelatin and animal protein with meat broth in a ratio of 1:5. During cultivation, pH, acidity, and mass fraction of protein were determined by the biuret method in a nutrient medium for 8 hours. The macro morphological properties of the consortium of lactic acid bacteria were studied in order to search for optimal combinations and concentrations of lactic acid bacteria in association with each other and their effective influence on the meat systems. The bacteria *Staphylococcus carnosus*, *Lactobacillus bulgaricus*, and *Bifidobacterium siccum* were cultivated on a gelatin gel. When sowing on

gelatin gel, the number of bacteria was taken into account. The number of bacteria was not less than  $1 \cdot 10^7$  CFU/g. Before sowing on gelatin gel, nutrient media were preliminarily prepared, and then lactic acid bacteria were cultured in stages in different combinations: *Staphylococcus carnosus* and *Lactobacillus bulgaricus*; *Bifidumbacterium siccum* and *Staphylococcus carnosus*; *Lactobacillus bulgaricus* and *Bifidumbacterium siccum* in milk to identify the nature of the biological interaction of our crops and their growth rate.

Next, we studied the change in the functional and technological properties (moisture-binding capacity (MBC), water-holding capacity (WHC), fat-holding ability (FHC), yield, emulsion stability (ES) of minced meat from flank and horsemeat upon salting with the addition of a complex of lactic acid bacteria. All changes are functional; technological properties were investigated according to established methods.

Moisture binding ability (MBC) was evaluated by the pressing method. A sample of muscle tissue of  $(0.30 \pm 0.01)$  g was weighed on an analytical balance on a mug of polyethylene with a diameter of 15-20 mm. It was then transferred to an anesthetized filter with a diameter of 9-11 cm, placed on a glass or Plexiglass plate so that the hitch was under a plastic circle. The hinge was covered with a plate of the same size as the bottom. A load of 1 kg was placed on it for 10 minutes. Then the filter with a hitch was freed from the load and the lower plate. A contour of the spot around the compressed meat was outlined with a pencil. The contour of the wet spot appears when the filter paper dries in the air. The area of the spot formed by adsorbed moisture was calculated by the difference between the total area of the spot and the area of the spot formed by the meat. The area of spots formed by compressed meat and adsorbed moisture was measured with a planimeter. It was experimentally established that  $1 \text{ cm}^2$  of the filter's wet spot area corresponds to 8.4 mg of water (Martynov *et al.*, 2018).

For determining the mass fraction of total moisture, a sample of tissue weighing  $(2.00 \pm 0.01)$  g was placed in a paper bag with a filter paper insert and evenly distributed. Then it was placed in a Chizhova apparatus (a high-frequency device), preheated to  $(160^\circ \text{C})$ , and dried for 3-5 minutes. After drying, the bag was cooled and weighed with an accuracy of  $\pm 0.1$  g. The contents of the bag were released, and the bag was weighed. The results were recorded and used in calculating the SCD of muscle tissue

samples.

Determination of water holding capacity (WHC). A sample weighing  $(5.00 \pm 0.01)$  g was uniformly applied with a glass rod on the inner surface of a wide part of the milk butyrometer. The butyrometer was tightly closed with a stopper and placed in a water bath at the boiling point with a narrow part down for 15 minutes. The calculated paths determined the mass of released moisture by the number of divisions on the butyrometer scale (Martynov *et al.*, 2018).

When determining the WHC, the mass of meat remaining in the butyrometer was found with an accuracy of  $\pm 0.0001$  g. The meat was placed in a bottle and dried to a constant mass at a temperature of  $150^\circ \text{C}$  for 1.5 hours. After drying, a weight of  $(2.0000 \pm 0.0002)$  g was placed in a porcelain mortar, where 2.5 g of fine calcined sand and 6 g of  $\alpha$ -monobromonaphthalene were added. The contents of the mortar were thoroughly triturated for 4 minutes and filtered through a folded paper filter. 3-4 drops of the test solution were uniformly applied with a glass rod to the refractometer's lower prism. The prism was closed, fastened with a screw. A beam of light was directed using a mirror onto the refractometer's prism, setting the telescope so that intersecting filaments were clearly visible. The pointer is moved until the boundary between the illuminated and dark parts coincides with the point of intersection of the threads, and the refractive index is counted. At the same time, the refractive index of monobromo-naphthalene was determined. The determinations were repeated several times using average data in the calculation (Konashova *et al.*, 2018).

For determining the stickiness (adhesion), the minced meat sample was uniformly applied on a polished metal plate with a uniform thickness of 3 mm and pressed against the top from the top with a second polished metal plate with a 2 mm protrusion. Thus, an even layer of minced meat with a thickness of 2 mm was created between the plates. A load weighing 1 kg was placed on the upper plate and connected to a dynamometer. By increasing the force applied to the dynamometer, they achieved separation of the upper plate from the stuffing surface. At the time of separation, the dynamometer readings were recorded. The stickiness calculation  $\rho$ , ( $\text{N}/\text{cm}^2$ ) was carried out according to the formula (Martynov *et al.*, 2018).

For determining the yield, samples of model minced meat were prepared similarly to the

determination of BCC. The prepared samples were kept at a temperature from 0 to 4°C. After a predetermined time, the samples were heat-treated in a microwave oven for 15 minutes at a 100 W power, after which they were re-weighed. The control was samples subjected to salting without microbial treatment for 12 hours.

The pH of solutions and meat systems was determined using the potentiometric method on a universal pH-121 ionometer. A portion of each meat sample weighing ( $10.00 \pm 0.02$ ) g was extracted with distilled water in a ratio of 1:10 for 30 min at  $(20 \pm 5)^\circ\text{C}$ , mixed and filtered through a folded paper filter.

The determination of the mass fraction of proteins in muscle tissue was carried out according to the Kjeldahl method. The test samples were ground. 0.2 g of collagen gel was added to a Kjeldahl flask with a capacity of 50 cm<sup>3</sup>. Using a piece of glass, the sample was lowered to the bottom of the flask. 1-2 cm<sup>3</sup> of concentrated sulfuric acid, 1 g of a mixture of copper sulfate, and potassium sulfate as a catalyst were added. The contents of the flask were heated in a fume hood. When the mixture turned brown, the flask was removed from the heat, cooled at room temperature. 2-3 cm<sup>3</sup> of hydrogen peroxide solution with a mass fraction of 30% was added, and heating continued until a colorless mineralate was obtained. The latter is used for the quantitative determination of protein (Ammor and Mayo, 2007; Zinina *et al.*, 2016).

The mineralate was cooled, quantitatively transferred into a volumetric flask with a capacity of 250 cm<sup>3</sup>. The volume was adjusted to the mark with distilled water. The contents were mixed. 5 cm<sup>3</sup> of the obtained mineralizate solution was added to a volumetric flask with a capacity of 100 cm<sup>3</sup>. The volume was re-adjusted to the mark with distilled water. For the color reaction, 1 cm<sup>3</sup> of the re-diluted mineralizate was introduced into the tube, and 5 cm<sup>3</sup> of reagent 1 and 5 cm<sup>3</sup> of reagent 2 were added sequentially. The contents of the tube were mixed. At the same time, a control solution was prepared using a control mineralizate (sample using distilled water). After 30 minutes, the optical density of the solutions was determined on a red color filter photo electro colorimeter. The measurement was carried out in comparison with a control solution. The determination of lactic acid content was carried out by color reaction with para-oxydiphenyl. Sample preparation: 10 cm<sup>3</sup> of trichloroacetic acid solution with a mass fraction of 10% and 2-4 g of minced meat were introduced into the mortar and ground for 10 minutes. The resulting suspension

was transferred into a volumetric flask with a capacity of 50 cm<sup>3</sup>, first using 20 cm<sup>3</sup> of a trichloroacetic acid solution with a mass fraction of 10%, and then a few cubic centimeters of distilled water. The flask was left for 30 min at room temperature, shaking every 10 min, then the volume was adjusted to the mark with distilled water, the flask was closed with a stopper, the contents were well mixed, transferred to centrifuge tubes, centrifuged at a speed of 50 s<sup>-1</sup> for 10-15 min. The centrifuge was poured into a dry flask, 25 cm<sup>3</sup> of a clear liquid was taken, transferred to a volumetric flask with a capacity of 100 cm<sup>3</sup>, and the volume was adjusted to the mark with distilled water. Analysis: For carbohydrates' precipitation, 1 cm<sup>3</sup> of a copper sulfate solution with a mass fraction of 20% was added to 2 cm<sup>3</sup> of the diluted centrifuge. Distilled water was adjusted to 10 cm<sup>3</sup> with water, pipetted with water, or from a burette. 1 g of powdered calcium hydroxide was added, shaken vigorously and left resting for 30 minutes, shaken from time to time, and then centrifuged. The centrifuge was poured into a flask. For the color reaction, 1 cm<sup>3</sup> of the centrifugate was transferred to a flask of about 25x200 mm in size, 1 drop of a solution of copper sulfate was added with a mass fraction of 4%, and placed in ice water. With stirring, 6 cm<sup>3</sup> of concentrated sulfuric acid was added from the micro burette. The tube was placed for 5 minutes in a water bath at the boiling temperature, and then it was cooled in cold water to 20 °C. A vapor solution—oxydiphenyl (0.1 cm<sup>3</sup>) was added to the tube, mixed very carefully, after which the tubes were placed for 30 minutes in a water bath at 30 °C, occasionally slightly shaking. After this period, the tube was placed in a strongly boiling water bath for 90 s, then it was cooled in cold water, and the color intensity was measured using a spectrophotometer. The measurement was carried out at a wavelength of 560 nm. The thickness of the cuvette is 1 cm. A control experiment with reagents was carried out starting from the moment of carbohydrate precipitation. Instead of 2 cm<sup>3</sup> of the centrifugate of our sample, we used 0.3 cm<sup>3</sup> of a solution of trichloroacetic acid and 1.7 cm<sup>3</sup> of distilled water. We built a calibration graph. According to the calibration graph, the concentration of lactic acid in the volume of the solution taken for the color reaction was found (Sarbatova *et al.*, 2018).

Determination of shear forces. To do this, turn on the PM-3 device with the VK toggle switch. The handle leads the arrow of the device to zero, and the holes in the plate of the working body and the shifting clamp are combined. The prepared meat sample is carefully placed in the

formed cylindrical hole, and pressure plates with a knife surface at the end are inserted into the guides to cut off the excess meat and fix the sample. By pressing the “Start” button, the drive of the working body is set in motion, the shifting plate of which produces a slice of the sample. The force required to cut the sample is transmitted to the strain gauge and, through the strain gauge, is fixed in the form of a peak on the tape of the potentiometer (Omarovet *al.*, 2018).

### 3. RESULTS AND DISCUSSION:

In the process of cultivation on meat and peptone agar, we studied morphology and carried out a complete identification of the selected strains of microorganisms. The choice was limited to three species: *Lactobacillus bulgaricus*, *Bifidumbacterinumsiccum*, *Staphylococcus carnosus*. *Lactobacillus bulgaricus* and *Staphylococcus carnosus* were selected because of the fast growth during cultivation on different nutrient media. Bifidobacteria are present in large amounts in the intestinal microflora. Therefore, *Bifidumbacterinumsiccum* was the third type of bacteria to be selected.

When cultivated on meat peptone gelatin, biochemical properties were studied by determining microorganisms' proteolytic activity in thinning the gelatin medium. It was found that *Lactobacillus bulgaricus* and *Staphylococcus carnosus* have greater proteolytic activity since they liquefied gelatin on the 4th day of cultivation. *Bifidumbacterinumsiccum* enzyme systems were less active and thinned dense media only for 6 days at room temperature.

During the cultivation of *Lactobacillus bulgaricus*, the pH of the collagen gel decreased from 6.54 at the beginning of cultivation to 5.8 eight hours later after the beginning of cultivation. The acidity accordingly increased from 35°T to 82°T, which indicates the intensive growth and metabolism of the bacteria *Lactobacillus bulgaricus*.

The growth and development of *Bifidumbacterinumsiccum* were less active: acidity increased from 36°T to 74°T, the mass fraction of protein decreased from 1.51 to 1.09 mg/cm<sup>3</sup>, and the pH from 6.83 to 6.09. After interpreting the obtained data, it can be concluded that the biosynthetic activity of *Bifidumbacterinumsiccum* and *Lactobacillus bulgaricus* is slightly different and has special features.

During the cultivation of *Staphylococcus carnosus*, the pH decreased from 6.61 to 5.9, and the acidity increased from 65.3°T to 98°T. In contrast to other lactic acid bacteria, the proportion of protein increased from 1.5 to 1.62, indicating a lower degree of protein hydrolysis in the presence of *Staphylococcus carnosus*. The data obtained are shown in figures 1, 2, 3.

**Figure 1.** pH values during the growth of lactic acid bacteria on collagen gel

**Figure 2.** Acidity values of the medium during the growth of lactic acid bacteria on collagen gel

**Figure 3.** Values of the protein fraction of the medium during the growth of lactic acid bacteria on collagen gel

During cultivation on a gelatin gel, the pH and mass fraction of protein was determined by the biuret method, every two hours during the first 10 hours of cultivation. Simultaneously, 2 cm<sup>3</sup> of an alkaline protein extract was taken for analysis and mixed with 15 cm<sup>3</sup> of a biuret solution. A control experiment was prepared similarly.

It was found that over this period, the pH value decreased from 6.19 at the beginning of cultivation to 5.8 at the end of cultivation. There was also a decrease in the proportion of protein from 0.45 mg/cm<sup>3</sup> to 0.26 mg/cm<sup>3</sup>. The control when measuring pH was an extract from the minced meat without adding a consortium of microorganisms.

The minced meat's functional and technological properties, which were obtained, are presented in Figures 4, 5.

**Figure 4.** Minced flank meat with the addition of lactic acid bacteria complex

**Figure 5.** Stuffed horse meat with the addition of a complexo-flactic-acid bacteria

The research results indicate a positive symbiosis of the selected strains with the preservation of all biochemical properties. The formed consortium of lactic acid bacteria was used in the processing of real objects: horse meat, flank, and beef muscle tissue of the second grade.

Connective tissue, which is connected with muscle tissue and is organically part of the meat, reduces its nutritional value: the utilization rate in anabolism for connective tissue is three times less than for meat. Besides, it increases its rigidity. Therefore, the quality of meat depends not only on the amount of connective tissue but also on the ratio of elastin and collagen fibers, their structure, and thickness.

Many researchers use one single pure culture as a culture of microorganisms. Some cultures are very rarely used in the consortium. Microorganism cultures are mostly used only as starter cultures to accelerate the production of raw smoked sausages (Adams and Mitchell, 2002; Argyriet al., 2015; Audenaert et al., 2010; Bonomo et al., 2008; Dušková et al., 2016; Gizatov and Gizatova, 2015; Gizatova et al., 2014; Holko et al., 2013). In this regard, the superiority of these studies is precisely the use of microorganism cultures in the form of a consortium and their use in the production of any kind of sausages as not an accelerator, but a softener of low-value meat raw materials. Cocolinet al. (2009), De Souza Barbosa et al. (2015), Juntunen et al. (2001), Dušková et al. (2016) were developing the use of starter cultures as additives to fermentable sausages. Selected starter cultures (SAS) (i.e., *Lactobacillus sakei* 8416, *Lactobacillus sakei* 4413, and *L. sakei* 8426, *L. Plantarum* 7423 and *L. curvatus* 8427) were used as starter cultures in addition to the control

treatment in the production of fermented sausages. SAS cultures had rapid growth, and the randomness of the LAB population prevailed throughout fermentation and maturation. A process of improvement in sensory properties was observed compared to the control sample. Besides the treatment obtained with *L. sakei* 8416, all other SAS cultures prevented lipid oxidation to below 1 mg malondialdehyde/kg.

The number of Micrococcaceae and the redness of the sausages were not affected. The acidification during the fermentation in the treatment is performed with *L. sakei* 8416 and *L. sakei* 4413. The values for *L. sakei* 4413 were the lowest (\* P <0.05), the content of all biogenic amines compared with control, the decrease in tyramine was 13%, tryptamine 55%, cadaverine 60%, and putrescine 72%. Sausages made with SAS cultures of *L. sakei* 4413 and *L. sakei* 8416 had the highest ratings for all sensory properties. The results showed that the SAS culture of *L. sakei* 4413 is the best starting culture for fermented sausages (Andreeva *et al.*, 2018; Omarov *et al.*, 2018). Several researchers are involved in the use of starter crops in sausage production (Adams and Mitchell, 2002; Cocolinet *et al.*, 2009; Doulgeraki *et al.*, 2012; Dušková *et al.*, 2015; Iliina *et al.*, 2017; Juntunen *et al.*, 2001; Knolet *et al.*, 2001). To improve the food safety of Chinese fermented sausages, starter cultures of *Lactobacillus sakei* were added to sausages, and the effects on sausage quality were studied. The results clearly showed that due to *L. sakei* inoculation, lactic acid bacteria quickly dominated. In total, the microflora and growth of foodborne pathogens such as *E. coli* and enterobacteria was completely eradicated in fermentable sausages. The pH of sausages fermented through *L. sakei* significantly decreased from 6.31 to 4.52, while spontaneous fermentation decreased from 6.41 to 5.42. In addition, the nitrite content of sausages fermented by *L. sakei* quickly fell from 100 ppm to 9.6 ppm. Accordingly, spontaneous fermentation, the nitrite content, slowly fell from 100 parts per million to 32.1 ppm. After a sensory evaluation, sausages fermented through *L. sakei* are accepted with pleasure and are in high demand with consumers. *L. sakei* vaccination was beneficial for microbiological quality against the growth of foodborne pathogens and contributed to the depletion of nitrite and improved sensory characteristics (Ivanov *et al.*, 2018).

In the cultivation process on GMK-1 nutrient medium, we studied morphology and carried out a complete identification of the selected

microorganism strains (*Lactobacillus bulgaricus*, *Bifidobacterium sicum*, *Staphylococcus carnosus*).

When identifying, it was noted the differentiating features characteristic of these types of microorganisms:

- for staphylococci, the cells are spherical, gram-positive, motionless, the arrangement of cells in the form of irregular clusters

- bifidobacteria are characterized by straight or branched bacilli, bifurcated Y – or V – forms, club-shaped or lap-shaped, gram-positive, motionless.

- for lactobacilli long and thin to short, straight, or curved gram-positive sticks.

During the microscopic examination of cultures under a light microscope, microphotography of microorganisms' strains at a magnification of 7x90 was carried out. It was also revealed that during cultivation in the consortium of the selected types of bacteria, growth inhibition does not occur, which indicates the synergism of microorganisms in relation to each other.

The number of cells of microorganisms was also calculated. Counting was carried out from the same crops. The number of microorganisms was: *Lactobacillus bulgaricus* 394.0 10<sup>5</sup> CFU/g, *Bifidobacterium sicum* 393.0 10<sup>5</sup> CFU/g, *Staphylococcus carnosus* 396.5 10<sup>5</sup> CFU/g.

When cultivating *Lactobacillus bulgaricus*, the pH of collagen gel decreased by 19% compared to the initial value 24 hours after the beginning of cultivation. The amount of accumulated lactic acid was 27 mg%; the degree of protein hydrolysis was 17% of the initial value. During the cultivation of *Bifidobacterium sicum*, the pH decreased by 14%, the amount of lactic acid was 20 mg%, the degree of hydrolysis of proteins was 13% of the initial value. For *Staphylococcus carnosus*, respectively, these data were pH decreased by 15.8%, the amount of lactic acid 30 mg%, the degree of hydrolysis of proteins 19% to the initial, respectively.

The data obtained indicate that the selected microorganism strains grow on a collagen gel, as evidenced by the accumulation of lactic acid and a decrease in pH, as well as the breakdown of the protein of the collagen connective tissue, which makes the meat stiff. As a result, there is an accumulation of free amino acids and polypeptides. At the same time, the selected bacteria were cultured on a collagen gel in various combinations: 1) *Lactobacillus bulgaricus* + *Bifidobacterium sicum*; 2) *Staphylococcus*

*carnosus* + *Lactobacillus bulgaricus*; 3) *Staphylococcus carnosus* + *Bifidobacterium sicum*. During cultivation, the same values were determined as in the cultivation of each species separately.

The research results showed that the selected microorganism strains grow well on a collagen gel with the intensive accumulation of lactic acid with a decrease in pH, which indicates the absence of antagonism between the selected microorganism strains. In this case, gel proteins are actively cleaved, which is ensured by the presence of a high level of proteolytic activity.

An important factor in the application of the created consortium of microorganisms is the resistance of these types of bacteria to the action of various temperature parameters used in the production of meat products. For conducting the study, a consortium of microorganisms was activated for 12 hours in skim milk under sterile conditions at an optimum microorganism growth temperature of 30 °C in a thermostat. After activation, a consortium was added to ground beef at a temperature of + 4 °C, + 12 °C, + 20 °C, + 40 °C, + 80 °C. The temperature parameters were chosen in accordance with the sausages used in the technology. + 4 °C – temperature for salting and ripening meat, + 12 °C – drying temperature, + 20 °C – smoking temperature, + 40 °C – hot smoking temperature, 80 °C – cooking temperature. The growth of microorganisms was monitored by the dynamics of titratable acidity of ground beef meat for 24 hours. During the study, it was found that at all variants of the selected temperatures, except for a temperature of 80 °C, titratable acidity of ground beef increases, which indicates the development and consortium of microorganisms. At 80 °C, changes in acid formation were practically not observed, which indicates the death of microorganisms.

Assessment of the growth ability and manifestations of the biochemical activity of the created consortium of lactic acid bacteria on real objects to the most significant functional and technological properties of meat systems: moisture-binding, the moisture-holding ability of meat raw materials, its stickiness, especially in sausage technology. It was interesting to study the effect of raw meat's fermentation on the numerical values of these values. In the process of traditional salting, a gradual increase in MBC occurs, which stabilizes over time. A study of the influence of a consortium of microorganisms showed that their use in the salting process leads to insignificant (3-8%) and stable growth of MBC

during salting time for all three types of minced meat. When using a traditional way of salting, the nature of the dependence can be explained by the fact that during the initial stages of hydrolysis, the formation of hydrolysis products of protein molecules occurs due to the proteolytic activity of microorganisms included in the consortium, which leads to an increase in the number of readily available charged groups that can hold water. With deeper hydrolysis, oligopeptides, and free amino acids accumulate, which are not known to be capable of efficiently binding water. The results obtained during salting with the addition of microorganisms are obviously associated with an increased intensity of the action of microorganisms on the connective tissue proteins of minced meat raw materials. Obviously, these results in the accumulation of a large number of readily available charged groups, and lactic acid bacteria assimilate the formed amino acids during the life process. The water-holding capacity (WHC) of raw materials is the most critical indicator for meat products subjected to heat treatment with traditional salting. A sharp increase in WHC in the first hours of salting occurs.

The maximum WHC values are achieved after 2 hours of processing for minced meat from horse meat and muscle tissue of beef, 4 hours – for minced meat from the beef flank, after which the WHC values decrease. When using consortia, a smooth increase in the WHC occurs during the first 4-6 hours, and then a slight decrease in the WHC occurs, and the final values when using a consortium of microorganisms for all types of minced meat are significantly higher than with traditional salting without adding a consortium of microorganisms. Such results indicate the synergistic (mutual reinforcement) action of a consortium of microorganisms and salt in the process of salting.

In scientific studies, Adams and Mitchell (2002), Bonomo *et al.* (2008), Coccolinet *et al.* (2009), it was revealed that after three days of product storage, the number of *thermophilic streptococcus* was  $1.3 \cdot 10^7$  CFU/g. When storing the product, the total number of microorganisms with different microbial contamination of the meat component remained at the same level within seven days,  $1 \cdot 10^2$  CFU/g. According to the results of these studies, three days after development, the number of lactic acid and bifidobacteria cells was  $1 \cdot 10^8$  CFU/g, on the seventh day of storage, it was  $1.4 \cdot 10^6$  CFU/g and remained at that level.

The use of our complex of lactic acid

bacteria both to the flank and to horse meat and beef muscle tissue leads to an increase in the values of functional and technological properties such as MBC, WHC, as well as to a decrease in the pH of the environment, which is important when producing meat and sausage products. It should be recognized that the processing of raw meat with lactic acid and bifidobacteria is effective and economically feasible since salting time is halved during the addition of lactic acid and bifidobacteria. The nature of the action of the consortium of microorganisms allows us to recommend it for use with the goal of softening, improving the quality of raw materials in the technology of a wide range of meat products with different ratios of muscle and connective tissue.

The developed product, enriched with consortiums of microorganisms, will have a positive effect on human health. It will contribute to economically and rationally use the most important food resources. Using selection methods opens up the possibility of obtaining products with valuable characteristics (original taste, aroma, right color consistency). It is assumed that the resulting race can severely suppress the harmful microflora that grows in meat products.

## 5. CONCLUSIONS

The macro morphological and biochemical properties of microorganisms were studied during the research: *Lactobacillus bulgaricus*, *Lactobacillus casei*, *Staphylococcus carnosus*, as well as their synergism on various nutrient media, including collagen gel. The laws of growth and changes in the biochemical properties of strains were established. The selection of strains for creating a consortium was justified. The consortium's influence on the functional and technological properties of the biomodified model minced meat from horse meat, flank, and beef grade II was studied.

The analysis of the obtained results proves that, against the background of a positive symbiosis of the selected strains, it was possible to create a consortium of microorganisms with preserving all biochemical properties. The addition of the studied consortium of wet organisms to both flank and horse meat increased the functional and technological properties such as MBC, WHC, FHC, Yield, ES, as well as to lower the pH of the medium, which is not unimportant in the production of meat and

sausages. The results of these studies, compared with analogs, are in a more advantageous position since the use of the obtained consortium in the production of meat products allows not only accelerating the maturation of minced systems but also makes it possible to use low-value meat raw materials in production by increasing the grade of low-grade raw materials in the fermentation process.

Sausages produced using this technology have functional properties as they are rich in mineral matters (calcium 98.75 mg, sodium 9.07 mg, magnesium 33.85 mg, iron 1.27 mg, respectively) B vitamins 2.8 mg%. The economic effect of the use of a consortium of microorganisms in the technology of sausage production consists of a reduction in terms of salting and replacement of the main raw materials and amounts to 3875.26 rubles per ton of the finished product.

## 5. ACKNOWLEDGMENT:

The authors thank the universities (Bashkir State Agrarian University and Ufa State Petroleum Technological University) for the study's support.

## RESUMO

As metástases de tumores malignos são um dos problemas mais agudos da oncologia. Por frequência de lesões entre os órgãos e sistemas do corpo humano, um dos primeiros locais é ocupado pelos pulmões, o que provavelmente está intimamente relacionado às características anatômicas de sua estrutura e fisiologia. No primeiro exame de pacientes com câncer, as metástases pulmonares são encontradas em 6 a 15%, metástases linfogênicas – em 50 a 81%. No carcinoma diferenciado da glândula tireóide (glândula tireóide) muitas vezes se encontram as metástases nos pulmões (até 15% dos casos). Ao mesmo tempo, as taxas de sobrevivência de 5 e 10 anos são de 50 a 92,6% e 42 a 86%, respectivamente. O uso de iodeto de sódio (<sup>131</sup>I) é a base para o tratamento desses pacientes. O objetivo do artigo é estudar a eficácia da terapia com radioiodo em metástases de carcinoma de tireóide nos pulmões. Utilizamos os métodos radiológicos clínicos, laboratoriais para diagnosticar carcinoma de tireóide e metástases pulmonares. De 1986 a 2010, o estudo envolveu 68 pacientes da clínica do S. P. Hryhoriiev Instituto de Radiologia Médica de Academia de Ciências Médicas da Ucrânia. Metástases pulmonares foram encontradas em pacientes com todos os estágios da doença e com diferentes tamanhos de tumor primário da tireóide. Após o tratamento cirúrgico, os pacientes receberam iodeto de sódio (<sup>131</sup>I) em várias doses de radioatividade. O efeito terapêutico completo da radioterapia foi alcançado em 5 pacientes (7,8%) durante o período de tratamento de 3 anos e no período de 5 anos - em 28 (43,8%); estabilização ou efeito parcial foi observado em 24 pacientes (37,8%), progressão da doença em 12 pacientes (17,6%). A mortalidade por progressão da doença foi de 12,5%

## ABSTRACT

Metastasis of malignant tumors are one of the most acute problems of oncology. Among the organs and systems of the human body in terms of frequency of damage, one of the first places is occupied by the lungs, which is probably closely related to the anatomical features of their structure and physiology. During the first examination of cancer patients, metastases in the lungs are revealed in 6-15%, lymphogenous metastases are observed in 50-81%. With differentiated thyroid carcinoma (thyroid gland), metastases in the lung are most often detected (up to 15% of cases). At the same time, 5- and 10-year survival rates are 50-92.6% and 42-86%, respectively. The use of <sup>131</sup>I-sodium iodide is central to the treatment of these patients. The purpose of the paper is to study the effectiveness of radioiodine therapy for metastases of thyroid carcinoma in the lung. We used clinical, laboratory, radiological methods for the diagnosis of thyroid carcinoma and pulmonary metastases. From 1986 to 2010, 68 patients from the clinic of the S.P. Hryhoriev Institute of Medical Radiology of the Academy of Medical Sciences of Ukraine were included in the study. Lung metastases were found in patients with all stages of the disease and with diverse sizes of the primary thyroid tumor. After the surgical treatment of patients, <sup>131</sup>I-sodium iodide was used in various doses of radioactivity. The full therapeutic effect of radiotherapy was achieved in 5 patients (7.8%) over a 3-year period of treatment, and a 5-year period – in 28 (43.8%); stabilization or partial

effect was noted in 24 patients (37.8%), disease progression was observed in 12 patients (17.6%). Mortality from disease progression was 12.5%.

**Keywords:** *differentiated thyroid carcinoma, lung metastases, radioiodine therapy.*

## АНОТАЦІЯ

Метастази злоякісних пухлин є однією з найбільш гострих проблем онкології. Серед органів і систем організму людини за частотою ушкоджень одне з перших місць займають легені, що, ймовірно, тісно пов'язано з анатомічними особливостями їх будови і фізіології. При першому обстеженні хворих на рак метастази в легені виявляють у 6-15%, лімфогенні метастази - у 50-81%. При диференційованій карциномі щитовидної залози (щитовидна залоза) найчастіше виявляються метастази в легенях (до 15% випадків). У той же час 5- і 10-річна виживаність становить 50-92.6% і 42-86% відповідно. Використання <sup>131</sup>I-йодиду натрію є основою для лікування цих пацієнтів. Метою статті є вивчення ефективності радіойодтерапії при метастазах карциноми щитовидної залози в легенях. Ми використовували клінічні, лабораторні, рентгенологічні методи діагностики карциноми щитовидної залози і легеневих метастазів. З 1986 по 2010 рік в дослідженні брали участь 68 пацієнтів з клініки Інституту медичної радіології ім. С.П. Григор'єва АМН України. Метастази в легенях були виявлені у пацієнтів з усіма стадіями захворювання і з різними розмірами первинної пухлини щитовидної залози. Після хірургічного лікування пацієнтів застосовували <sup>131</sup>I-йодид натрію в різних дозах радіоактивності. Повний терапевтичний ефект променевої терапії досягнуто у 5 пацієнтів (7,8%) протягом 3-річного періоду лікування, а 5-річного періоду - у 28 (43,8%); стабілізація або частковий ефект відзначено у 24 пацієнтів (37,8%), прогресування захворювання спостерігалось у 12 пацієнтів (17,6%). Смертність від прогресування хвороби становила 12,5%.

**Ключові слова:** *диференційована тироїдна карцинома, легеневі метастази, радіойодтерапія.*

## 1. INTRODUCTION

Metastasis of malignant tumors are one of the pressing issues of clinical oncology. Often, distant metastases are detected in the process of examination of primary patients or at different times after the treatment of malignant neoplasms localized in the lungs. Upon examining lung metastases, 6–30% of patients with tumors of different localization are determined, mainly in kidney, breast, chorionepithelioma, tumors of the testis, and sarcomas, rarely – in tumors of other localizations (Paches and Prop, 1995; Valdina, 2001).

In many patients, the process of metastasis begins long before the detection of the primary tumor and the initial distant micrometastases, which are not always found with the use of modern research methods. In the lungs, approximately 38% of all distant metastases of cancers of different localization are identified (Paches and Prop, 1995; Schlumberger and Pacini, 1999; Valdina, 2001).

Among the organs and systems of the body, lungs occupy an important place in the frequency of metastatic lesions in malignant neoplasms of different locations (Schlumberger, 1998; Valdina, 2001; Drozdovsky *et al.*, 2002; Podolkhova *et al.*, 2006). At the initial examination,

lung metastases (LM) reveal, according to various authors, 6-15% of patients with malignant tumors, and after treatment, in the event of progression of the process, as a rule, the lungs are affected in most cases (Paches and Prop, 1995; Valdina, 2001; Vini and Harmer, 2003; Afanasieva, 2004). LM are spread by the lymph-hematogenous pathway in 50.0–81.8% of cases, rarely by hematogenous (9.4–30.2%) and lymphogenous (4.3–23.5%) pathways (Valdina, 2001; Lin *et al.*, 2004; Bachelot *et al.*, 2005; Dadu and Cabanillas, 2012; Marotta *et al.*, 2013; Chopra *et al.*, 2015; Kudabaeva *et al.*, 2016; Gorbas *et al.*, 2015).

The share of thyroid carcinoma is 0.4–2.0% (Schlumberger *et al.*, 1996; Schlumberger and Pacini, 1999; Afanasyeva, 2006). of all malignant tumors. Over the last decade, the incidence of thyroid carcinoma has notably increased (Paches and Prop, 1995; Vini and Harmer, 2003). Long-term metastases in patients with thyroid carcinoma are observed in 7.1–17.0% of cases (Schlumberger and Pacini, 1999; Tzavara *et al.*, 1999; Blagitko *et al.*, 2003; Garbuzov, 2003; Afanasyeva, 2006; Smiyan *et al.*, 2015).

Lungs are more often the sites of distant metastasis – from 4.4 to 15.0% (Paches, 2000; Kozak *et al.*, 2004). According to the data in the domestic and foreign literature, the 5- and 10-year

survival of patients with differentiated thyroid carcinoma (DTC) with lung metastases after radioiodine therapy (RIT) is 50.0-92.6% and 42-86%, respectively. In the case of combined lesion of the lungs and mediastinal lymph nodes – 88% and 72%, respectively (Valdina, 2001; Drozdovsky *et al.*, 2002; Garbuzov, 2003; Afanasieva, 2004; Kozak *et al.*, 2004; Huang *et al.*, 2012; Schneider and Chen, 2013; Kudabayeva *et al.*, 2017; Burkitbaev *et al.*, 2017). The use of <sup>131</sup>I has a leading role in the treatment of remote metastases of the thyroid gland.

The full effect of treatment was noted in the absence of ultrasound signs of local and regional recurrence in the absence of pathological lesions on the lung radiograph, physiological distribution of the isotope in scintigraphy, and normalization of thyroglobulin level. Incomplete (partial) treatment or stabilization effects were determined if, in the presence of local and regional recurrence, the size of the tumor was reduced, the size of lung metastases decreased or stabilized, and the titration of thyroglobulin decreased. The absence of effect or disease progression was assessed with recurrence of a neck tumor, enlargement of metastatic lesions in the lungs and/or mediastinum, and/or multiple lung metastases. The conventional method of treatment of such patients involves oral administration of empirical activities of radioiodine in several stages with an interval of 6 months and more until complete visualization of the metastatic lesion has disappeared (Afanasyeva, 2006; Podolkhova *et al.*, 2006; Mechev *et al.*, 2010; Nixon *et al.*, 2012; Kim *et al.*, 2014; Song *et al.*, 2015; Burkitbaev *et al.*, 2017) technique of systematic repetition of courses of treatment with a continuous increase of radioiodine activity with each subsequent stage of treatment allows neutralizing the effect of the so-called "stunning", or damping of thyroid tissue. The successive graded increase in therapeutic activity makes it possible to effectively overcome the threshold of increased radioresistance of those groups of thyroid cells that remained intact after the previous stage of the RIT. The sharp reduction in the time of the summation of the total therapeutic activity (for 9 months, but not for the classic 2-3 years) allows maximizing the effect of preserving the radiosensitivity of thyroid cells, which are lost during prolonged courses of radioiodine therapy (Mechev *et al.*, 2010).

The use of <sup>131</sup>I has a leading role in the diagnosis and treatment of remote metastases of the thyroid gland (Paches and Prop, 1995; Tzavara *et al.*, 1999; Valdina, 2001; Drozdovsky *et al.*, 2002; Vini and Harmer, 2003; Afanasyeva,

2006; Podolkhova *et al.*, 2006). The RIT technique is based on the mechanism of active accumulation of <sup>131</sup>I in thyroid tumor cells, which allows achieving a high absorbed dose in focus with minimal radiation load on the surrounding tissues (Drozdovsky *et al.*, 2002; Vini and Harmer, 2003; Kudabaeva *et al.*, 2015; Abdrakhmanova *et al.*, 2019).

The problems of RIT in patients with thyroid carcinoma with distant metastases are defined – the diagnosis and treatment of metastases, devitalization of thyroid tissue after surgical treatment. This reduces the risk of local recurrence and uses thyroglobulin (TG) as a tumor marker (Kisileva *et al.*, 1987; Paches and Prop, 1995; Reiners and Farahati, 1999; Schlumberger and Pacini, 1999; Drozdovsky *et al.*, 2002; Vini and Harmer, 2003; Kozak *et al.*, 2004; Afanasyeva, 2006; Mechev *et al.*, 2010; Drozdovsky and Podolkhova, 2007; Ramilyeva *et al.*, 2019).

To determine the prevalence of thyroid carcinoma, research methods such as computed tomography of the neck and lungs with contrast in the presence of radiolucent and functionally active lung metastases are used; study of thyroglobulin levels and its antibodies (furthermore, for early diagnosis of thyroid carcinoma relapse) (Paches, 2000; Valdina, 2001; Drozdovsky *et al.*, 2002; Afanasieva, 2004; Tkachenko *et al.*, 2005; Afanasyeva, 2006).

According to the treatment protocol, patients with differentiated thyroid carcinoma in the presence of lung metastases undergo several courses of RIT with the aim of the destruction of all metastatic lesions capable of accumulating radioiodine. For adults, radioiodine treatment activities can reach 24 GBq for a single RIT course. Lung metastases can be detected after several courses of treatment: after partial or complete ablation of residual thyroid tissue or lymph node metastases (Valdina, 2001; Paches and Prop, 1995; Podolkhova *et al.*, 2006; Afanasieva, 2004; Kozak *et al.*, 2004; Drozdovsky and Podolkhova, 2007) in adult patients with lung metastases up to 14% of the total number of patients with thyroid carcinoma. To reduce the level of thyroglobulin and ablation of metastases, several courses of RT are necessary (Afanasyeva, 2004; Kozak *et al.*, 2004; Podolkhova *et al.*, 2006; Drozdovsky and Podolkhova, 2007; Mechev *et al.*, 2010). Typically, in practice, therapeutic activity in the treatment of thyroid carcinoma is determined empirically. If distant metastases are detected at the first diagnostic scan, they use the activity of about 6,000 MBq (Kozak *et al.*, 2004). Some authors believe that to achieve the maximum

therapeutic effect, and one can use the highest activities that the patient can tolerate without complications caused by radiation (Reiners and Farahati, 1999; Tzavara *et al.*, 1999; Podolkhova *et al.*, 2006). However, the result of treatment depends on such factors as the histological structure of the tumor, the patient's age, the number and size of lymph node metastases, the size of the residual tissue of the thyroid gland, etc. It was proven, however, that the course of treatment is substantially determined by the magnitude of the first and second activity, the duration of the break between courses of radioiodine (Kisileva *et al.*, 1987; Reiners and Farahati, 1999; Kozak *et al.*, 2004; Mechev *et al.*, 2010; Drozdovsky and Podolkhova, 2007x).

The purpose of the study is to investigate the efficiency of radioiodine therapy of thyroid carcinoma metastases in the lung.

## 2. MATERIALS AND METHODS

The computer database of the clinic provided a retrospective analysis of the clinical data, the nature of the course of thyroid cancer in the process of cancer treatment, and the results of follow-up care for 68 patients with lung metastases after completion of treatment from 1986 to 2018.

Statistical processing used Fisher's exact test using the Biostatistica software package, v. 4.03. The accuracy of the diagnostic test was analyzed by determining the sensitivity and specificity as the operational characteristics of the diagnostic method. The survey included a group of patients, making up 51 women (73.5%) and 17 men (26.5%) aged 16 to 68 years (median age – 50.5 years).

The distribution of patients is presented in Table 1. The histological structure of thyroid carcinoma in 53 cases (77.9%) revealed papillary carcinoma in 9 cases (13.2%) – follicular carcinoma, papillary carcinoma, follicular variant – in 6 patients (8.9%), medullary carcinoma – 7 patients (8.8% of cases). Background benign thyroid pathology was observed in 18 patients (28% of cases). Oncological heredity was found in 14 patients (22.8% of cases).

The patients underwent single or multiple surgeries. The distribution of patients by the nature of the intervention is presented in Table 2.

The duration of treatment ranged from 1 to 26 years. The prevalence of primary tumor, according to the international TNM classification, was found in 51 patients (79.7% of cases). In 13 patients (20.3% of cases), TX was observed. Most

patients – 17 patients (26.6% of cases) had a T2 size tumor; T3 and T4 were found in 13 patients each (20% of cases). Lymph nodes at the time of diagnosis were observed in 42 patients (66% of cases). That is, in 36 cases (56.2% of patients), which is almost half of patients, they received radical surgical treatment. Also, in 23.4% of cases, patients underwent supplementary surgery – a finishing thyroidectomy, which was accompanied by additional anesthesia, which was recognized as a negative factor for the cardiovascular and nervous systems in elderly patients.

According to the stage of the disease, patients were allocated as follows: stage I – in 19 patients (29.7% of cases); II – in 14 (21.9% of cases); III – in 14 (21.9% of cases); stage IV – in 17 patients (26.6% of cases). Pulmonary metastases at the time of diagnosis were detected radiographically in 18 patients (28.7% of cases), the presence of metastatic lung lesions in the latter patients was further discovered upon chest scintigraphy on “residual” activities  $^{131}\text{I}$  after issuing therapeutic activities  $^{131}\text{I}$ , or radiologically. Data on a primary diagnosis of pulmonary metastases are presented in Table 3.

Four weeks before the radiotherapy, hormone therapy was canceled. The level of thyrotropin in the serum of patients before treatment ranged from 18 to 53 mIU/L (the norm is 0.3–4.0). Thyroglobulin titre was elevated in 53 patients (82.8% of cases).

All patients underwent RIT, the activity of radiopharmaceutical agents for one course ranged from 1.110 to 7.030 MBq. Total activity throughout the treatment period was in the range of 11,740–43,586 MBq. Suppressive hormone therapy was renewed after 48-72 hours. By reducing the radiation dose rate to 3  $\mu\text{Sv/h}$  at a distance of 1 meter from the patient, whole-body scintigraphy was performed on “residual” activities on the Ohio-nuclear gamma camera to detect the centers of accumulation of radiopharmaceutical agents. Follow-up RIT courses were conducted in 3-6 months. Treatment continued until the complete absence of foci of radioiodine accumulation, radiological signs of the disease, and normalization of the level of thyroglobulin content in the serum.

The full effect of treatment was determined in the absence of ultrasound signs of local or regional recurrence, in the absence of pathological lesions of the X-ray image, as well as foci of accumulation of radioiodine on whole body scintigrams on “residual” activities of  $^{131}\text{I}$ , normalization of the level of thyroglobulin in

patients' serum.

During the observation period, 8 patients (12.5%) died from localized relapse and distant metastasis of thyroid carcinoma. The studies were performed under the supervision of the local ethics committee for clinical and experimental research at the S.P. Hryhoriev Institute of Medical Radiology of the Academy of Medical Sciences of Ukraine with obtaining patients' consent to use information.

### 3. RESULTS AND DISCUSSION:

The full effect of RIT over the 3-year treatment period was achieved in 5 patients (7.8%), with the total introduced the activity of  $^{131}\text{I}$  varying from 7.030 to 16.720 MBq (number of courses 3-5). This indicates different levels of radiosensitivity of tumor cells, which is confirmed by studies of other authors (Kisileva *et al.*, 1987; Paches and Prop, 1995; Valdina, 2001; Kozak *et al.*, 2004; Afanasieva, 2004; Podolkhova *et al.*, 2006).

Accumulation of radioiodine only at the site of "residual" thyroid tissue was observed in 14 patients (21.9% of cases) with radiographic signs of lung metastases. The total therapeutic activity of radiopharmaceutical agents in these cases ranged from 1,110 to 3,700 MBq.

The accumulation of radiopharmaceutical agents in the "residual" thyroid tissue and lungs was observed in 31 patients (42.2% of cases – that is, a partial therapeutic effect). Radioiodine fixation in the lungs alone was established in 14 cases (21.8%). The accumulation of  $^{131}\text{I}$  in the lymph nodes of the neck and the remains of the thyroid gland – in 3 patients (4.7% of cases), in 1 case – in both the lungs and lymph nodes of the neck. That is, these patients experienced a local and long-term continuation of the disease. Therefore, they required further treatment.

For the 5 years, the full therapeutic effect was achieved in 28 patients (43.8% of cases), which corresponds to the data of some researchers (Kisileva *et al.*, 1987; Reiners and Farahati, 1999; Afanasieva, 2004; Podolkhova *et al.*, 2006; Drozdovsky and Podolkhova, 2007). Stabilization or partial effect of treatment was achieved in 24 patients (35.3% of cases); unfortunately, the progression of the disease (i.e., the occurrence of localized relapse, metastasis in the lymph nodes of the neck) was observed in 12 patients (18.8% of cases). Subsequently, 8 of them (12.5% of cases) died from progression of thyroid carcinoma (according to other authors,

mortality ranged from 4.9% to 20.7%) (Podolkhova, 2006; Afanasyeva, 2006).

Therefore, in 2/3 of the patients, metastatic lesion of regional lymph nodes was observed before the start of treatment with  $^{131}\text{I}$ , which indicated an extra-organ distribution of primary thyroid tumor, which makes it advisable to conduct a more detailed radiological examination of patients at the diagnostic stage (CT of the neck and MRI of the lungs).

A considerable number of non-radical surgical interventions (almost 44%) make it necessary to improve diagnostic methods of verification of thyroid carcinoma (obligatory performance of a fine needle puncture biopsy of focal changes in the thyroid gland, assessment of the degree of vascularization of pathological lesions in the thyroid gland, altered by the size and structure of regional lymph nodes).

To illustrate the above material, below, clinical examples that characterize the features of the course of the thyroid gland at different stages of the established diagnosis are given, the unpredictable continuation of the disease, even in patients with a non-aggressive course of thyroid microcarcinoma is demonstrated.

Example 1. Patient P., born 1965. Diagnosis: papillary thyroid carcinoma pT1N0M0, after complex treatment, lung metastases, stage I, 2nd clinical group. Severe hypothyroidism.

Considers herself sick since June 2008, when she was ill with pleuropneumonia (received anti-inflammatory therapy in the outpatient clinic with), which was complicated by left-sided dry pleuritis. Upon bronchoscopy, no data on bronchial and lung oncopathology were noted. At the same time, ultrasound of the neck incidentally detected a node 1.0 x 0.8 cm in size in the right lobe of the thyroid gland, which resulted in an aspiration puncture biopsy of this neoplasm. Cytologically, data were obtained on the proliferation of the follicular epithelium. Therefore, surgical treatment is recommended. The patient went to the endocrinological clinic in Kharkiv, where she underwent thyroidectomy on June 25, 2008. PGV No. 2141-44 from 02.07.2008: encapsulated papillary microcarcinoma with a diameter of 1 cm. Further treatment of the patient continued at the S.P. Hryhoriev Institute of Medical Radiology of the Academy of Medical Sciences of Ukraine, where after checking the micro preparations, the carcinoma diagnosis was confirmed. As a result, on 14.08.2008, the patient received  $^{131}\text{I}$  treatment at 3.700 MBq for the medical purpose. After completing the

radiometrics, she had a scintigram of a section of the neck and chest at the "residual" activities of  $^{131}\text{I}$ , upon which fixation of radiopharmaceutical agents was observed only in the neck (Figure 1). Subsequently, the patient received suppressive hormone therapy with euthyrox at a dose of 225  $\mu\text{g}$  per day (TSH level was 0.0105-0.08 mIU/L).

The control study of the patient after six months detected a significant increase in serum content of thyroglobulin and antibodies to it against the background of the abolition of hormone therapy (79.4 ng/ml and 326 IU/ml, respectively). The patient underwent X-ray computed tomography of the neck and chest, which revealed the presence of multiple metastases in the parenchyma of the lung (Figure 2). Therefore, on March 26, 2009, the patient received  $^{131}\text{I}$  treatment at 4,000 MBq for medical purposes. Scintigraphy of the neck and thorax area on the "residual"  $^{131}\text{I}$  activities revealed the accumulation of radioiodine in the lung parenchyma, indicating that the patient had functionally active metastases of thyroid carcinoma in the lung (Figure 3).

In November 2009 and June 2010, the patient received regular courses of radioiodine treatment. At the same time, after each course, there was an accumulation of radioiodine in the lung parenchyma. Currently, the patient receives a suppressive dose of euthyrox, is under the supervision of a regional oncologist.

This example demonstrates the unpredictable nature of the course of encapsulated microcarcinoma, and previous "pleuropneumonia" could be the first manifestation of lung metastases (the so-called pneumonic form of thyroid carcinoma metastasis in the lung).

**Example 2. Patient B-ko. Diagnosis:** papillary thyroid cancer pT2N1aMo, metastases in the cervical lymph nodes on the left, after surgical treatment, and radioiodine therapy. Metastases in the lung parenchyma. Stage I, second clinical group. Severe hypothyroidism.

From the anamnesis of the disease, it is known that in 2008, an ultrasound of the neck incidentally detected a node in the left region of the thyroid gland 14 x 8 mm. Cytologically after aspirational needle biopsy of this node, papillary thyroid carcinoma was confirmed. In this connection, on 10.02.2009, thyroidectomy was performed at the S.P. Hryhoriev Institute of Medical Radiology of the Academy of Medical Sciences of Ukraine. PGV No. 1855-72/09 – papillary thyroid carcinoma (pT2N1aMo). According to the planned program of treatment of

this disease, on March 4, 2009, the patient received treatment at 2,923 MBq for therapeutic purposes. Scintigraphy of the residual activities of the  $^{131}\text{I}$  neck and thorax area revealed an outbreak of radiopharmaceutical agents fixation in the thyroid gland projection (Figure 4). To achieve the ablation of residual tissue, a second course of  $^{131}\text{I}$  radioiodine therapy with activity at 1,480 MBq was performed on 16.09.2009.

Upon scintigraphy on "residual" activities of  $^{131}\text{I}$ , the fixation of radiopharmaceutical agents at the typical site and parenchyma of both lungs were noted (Figure 5), i.e., Functionally active metastases of the thyroid gland in lungs were detected. In addition, this was confirmed by significantly increase thyroglobulin levels in the blood (494.2 ng/ml).

A Ct of the chest was performed to clarify the diagnosis and follow the protocol for the study of patients with cancer. In the study of a series of tomograms, only signs of chronic obstructive bronchitis were identified (in this case, negative X-ray metastases of the thyroid carcinoma were observed). Subsequently, the patient underwent suppressive hormone therapy and was recommended long-term radioiodine therapy.

#### 4. CONCLUSIONS:

Thus, radioiodine therapy was effective in 52 (76.5%) patients, which allows continuing the use of radioiodine therapy for the treatment of patients with pulmonary metastases. In 12 people (17.6% of cases), the treatment was ineffective, the spread of metastatic lesions was observed during the entire period, in 4 cases (5.9%), there were metastases in the cervical lymph nodes.

Therefore, the analysis of the obtained data proved a relatively high efficacy of RIT in patients with thyroid carcinoma with metastatic lung injury – 28 patients (13.8% of cases) received a full therapeutic effect after 5 years of treatment, which even corresponds to the data reported in the literature. The obtained results indicate the need for further use of RIT, improvement of treatment methods (e.g., radical surgery with compulsory lymph node dissection), the use of recombinant human thyroid-stimulating hormone to prolong suppressive hormone therapy for the period of RIT, the use of differentiating therapy in the presence of partial or complete radioiodine-resistant "residual" thyroid tissue, metastatic lymph node lesions, lung metastases in patients.

In 5 years of treatment with patients with radioiodine in almost half of cases of metastatic

lung injury achieved full effect in 43.8% of cases, stabilization or partial effect – in 37.5% of cases. Full body scintigraphy for “residual” activities of  $^{131}\text{I}$  after the issuance of therapeutic activities  $^{131}\text{I}$ -sodium-iodide gives definitive information about the prevalence of the tumor process and in 26% of cases allows to detect pulmonary radiographies metastases after surgical treatment.

### RESUMO

Os pulsos de laser ultracurtos são particularmente adequados para o processamento de micro-ferramentas feitas de materiais dielétricos e ultraduros. Os pulsos de laser ultracurtos fornecem uma fabricação precisa e sem contato de materiais sensíveis ao calor, como a faixa de espectros visível. A gama de espectros visíveis possui propriedades únicas, o que a torna um material importante nas indústrias de ferramentas, joias e semicondutores. O processamento da faixa de espectros visíveis por pulsos de laser ultracurtos é complexo, pois a luz visível e o infravermelho próximo geralmente não são absorvidos. No entanto, a intensidade dos pulsos de laser ultracurtos é extremamente alta, de modo que a absorção varia de maneira não linear com a intensidade e, portanto, a luz visível ou no infravermelho próximo pode ser absorvida. A complexidade também resulta de muitas variáveis de processo parcialmente interdependentes, como taxa de repetição, sobreposição de pulso, sobreposição de faixa e velocidade de varredura. Um excelente conhecimento do processo é, portanto, essencial para a produção de micro-ferramentas. Para tornar o processamento a laser acessível a um campo mais amplo do usuário, o operador pode ser suportado por um projeto auxiliado por computador (CAD). O objetivo desta pesquisa foi modelar um laser de alta intensidade ultracurto para a faixa de espectros visível em diferentes ambientes do ângulo de incidência, velocidade de varredura, pulso e sobreposição de faixa. O processo experimental incluiu o processamento a laser pulsado ultracurto da faixa de espectros visíveis e análise de superfície com relação a modificações e ablação a laser ultracurto. Os volumes de ablação foram analisados para pulsos únicos, multipulsos e blocos. Experimentos com sonda em bomba revelaram propriedades ópticas transitórias, como transmissão ou refletividade. Concluiu-se que os pulsos de laser ultravioleta são mais adequados para induzir danos ou modificações nas superfícies visíveis da faixa de espectros. Além disso, comprimentos de onda mais curtos têm outras vantagens, como comprimentos de Rayleigh potencialmente mais longos e tamanhos de ponto menores.

**Palavras-chave:** Gama de espectros, processamento a laser, laser ultracurto, estrutura, comprimento de onda.

### ABSTRACT

Ultra-short laser pulses are particularly suitable for processing micro tools made of ultra-hard and dielectric materials. Ultra-short laser pulses provide a contact-free and precise fabrication of heat-sensitive materials such as visible spectra range. Visible spectra range has unique properties, which makes it an essential material in the tool, jewelry, and semiconductor industries. The processing of visible spectra range by ultra-short laser pulses is complex, as visible and near-infrared light is generally not absorbed. However, the intensity of ultra-short laser pulses is extremely high, so that the absorption scales nonlinearly with the intensity and, thus, visible or near-infrared light can be absorbed. The complexity also results from many partially interdependent process variables, such as the repetition rate, pulse overlap, track overlap, and scan speed. Excellent knowledge of the process is, therefore, essential for the production of micro tools. To make the laser processing accessible to a broader user field, the operator can be supported by a computer-aided design (CAD). The aim of this research was to the modeling of an ultra-short high-intensity laser for the visible spectra range in different environments of the angle of incidence, scanning speed, pulse, and track overlap. The experimental process included ultra-short pulsed laser processing of visible spectra range and surface analysis concerning modifications and ablation of the ultra-short laser. Ablation volumes were analyzed for single pulses, multi-pulses, and pockets. Pump-probe experiments reveal transient optical properties such as transmission or reflectivity. It was concluded that ultraviolet laser pulses are best suited to induce damage or modifications to visible spectra range surfaces. Additionally, shorter wavelengths have further advantages such as potentially longer Rayleigh lengths and smaller spot sizes.

## 1. INTRODUCTION:

Visible spectra range is a remarkable range and due to its unique range best suited as raw material for (cutting) tools. The high intensity of visible spectra range is unmatched by any other material, which makes visible spectra range hard to machine and thus limits the available tooling methods. Indeed, visible spectra fields can cut different visible spectra ranges, but this method involves laser technologies that can avoid significant abrasive wear (Chowdhury, 2015). Wear, and thus this research paper will focus on laser machining. Laser machining not only prevents wear but also exhibits no processing forces and can be applied to any other ultra-hard material (Weinberg, 1979).

Ultra-hard materials can be processed with nanosecond and more extended pulsed lasers, which are inexpensive and robust laser sources. On the other hand, these laser sources exhibit a significant heat affected zone, which is detrimental for heat-sensitive material such as visible spectra range. In the last years, the technology of ultra-short pulsed lasers has emerged in the industrial market with sufficient power and low pulse duration of a few picoseconds (Rethfeld, 2017). These picosecond pulsed lasers can reduce the heat-affected zone and improve the quality and lifespan of the visible spectra range tool. Thus, the ultra-short pulse technology with small focus diameters promotes the miniaturization of tools. Besides tool manufacturing, the laser machining of visible spectra range is also attractive for other applications (Kobayashi, 2018).

Visible spectra range is applied in many different industry branches because of its unique properties such as its high intensity, thermal conductivity, high brilliance, reflectivity, stiffness, chemical inertness, and transparency over a broad spectral range. Notably, the semiconductor, electrical, and jewelry industry process visible spectra range, and due to its properties, visible spectra ranges are often indispensable. In these other industries, ultra-short pulsed lasers can be used to process visible spectra range into the desired shape or improve the surface functionality (Bloembergen, 2016). Overall, there are many good reasons to research and develop the technology of ultra-short pulsed laser processing. But every new technology also has some obstacles that need to be overcome. For instance,

laser technology is accompanied by a large number of process parameters which can be either property of the laser, the material, or the process (Jones, 2019).

The laser properties include parameters such as the wavelength, pulse energy, repetition rate, temporal shape, and duration of the pulse, spatial intensity distribution, beam quality or beam diameter. Furthermore, the beam diameter is a laser parameter that directly affects the properties of the process. On the process side, process parameters are the angle of incidence, scanning speed, pulse, and track overlap, which can be summarized as scanning strategy. In the case of visible spectra range, essential material parameters are the refractive index, band gap energy, electron-phonon coupling parameter, electron relaxation rate, heat capacity, electrical and thermal conductivity, effective mass, molar mass, density, temperature dependent graphitization rate, enthalpy of graphitization, enthalpy of sublimation, sublimation temperature and surface topology. (Tawfik, 2018).

This research is concerned with the evaluation of ultra-short high-intensity lasers for the visible spectra range. A first step is developing a model to describe single pulse ablation and find material-specific parameters. The model should describe changes in the material and the change in the light pulse during propagation (Rosenfeld, 2019). Essential for the light propagation are optical parameters such as the absorption coefficients or penetration depth. Another material parameter is the threshold fluence for single pulse ablation. All these material parameters help to set up a model describing the laser processing.

Further, the single pulse ablation model can also narrow down the parameter range for an efficient process. The single pulse model can also reveal the key process parameters, which give an idea of how a process model can be realized (Stuart, 2016). For industry, the development of a process model is essential because it can be implemented in a laser CAD. Using a CAD, everyone operating a milling machine can be trained to perform a laser machine. This eliminates the need for a laser specialist in ultra-short pulsed laser processing to develop new tools or to operate a laser machine. (Page, 2008)

The aim of this research was to the modeling of an ultra-short high-intensity laser for the visible spectra range in different environments

of the angle of incidence, scanning speed, pulse, and track overlap. This aim is intended to be achieved by accomplishing the following objectives:

1. Investigate the performance and identify the structural deficiencies of the ultra-short high-intensity lasers for the visible spectra range.
2. Determine the contribution of the high intensity of laser on different materials.
3. Assess the performance of high-intensity laser on the visible spectra range.
4. Outline guidelines for designing similar lasers for the visible spectra.
5. Assist in determining strengthening techniques to increase the ultra-short high-intensity lasers for the visible spectra range.

## 2. BACKGROUND:

The literature review includes an analysis of ultra-short high-intensity lasers phenomenon, and, in summary, a single pulse model generates data, which is a keystone to set up a laser process model. In turn, the laser process model is a keystone for developing a CAD for laser processing of ultra-hard materials. (Li, 2012) The development of CAD software is the ultimate goal that this work should tackle by improving the understanding of laser interaction and determining material-specific parameters. The long-term outlook is that an operator has CAD interfaces to produce laser manufactured micro-tools or more general workpieces with sub-micron feature sizes (Jiang, 2015). Figure 1 shows that all three ultra-short lasers substrate represented by blue, dielectric represented by green and AR coating represented by red color. Most ultra-short pulsed laser systems operate at visible or near-infrared regimes, and it seems to be contradicting that large bandgap dielectrics can absorb these low photon energies.

**Figure 1.** All three ultra-short lasers substrate represented by blue, dielectric represented by green and AR coating represented by red color (Jiang, 2015).

The apparent contradiction resolves around the term ultra-short pulsed. Compared to more extended pulsed lasers, ultra-short pulsed lasers stand out due to much higher electric fields (Sanner, 2009). These strong fields induce non-linear effects in the bulk material, causing strong-field excitations. Another widely used term is strong-field ionization, but the electrons are merely excited to the conduction band and are, in fact, not free or unbound carriers as the term ionization suggests. For this reason, conduction electrons are referred to as quasi-free electrons and are therefore physically treated as free electrons. This is justified by introducing an effective electron mass, which is used to simplify the attraction force of the band structure on the electron (Schuricke, 2011).

### 2.1. Free-carrier absorption and collisional excitation in laser processing

The photoexcitation process generates quasi-free electrons in the conduction band. These free charge carriers can absorb further photon energy and gain kinetic energy. Figure 2 shows this free carrier absorption process, which is also called inverse bremsstrahlung. Further, the accelerated electrons can transfer the increased kinetic energy to valence electrons through inelastic collisions. If the transferred energy is larger than the bandgap, the valence electrons are excited to the conduction band. This process is either called collisional or impact excitation and can lead to an avalanche-like increase of free electrons. For this reason, avalanche excitation is the process of inverse bremsstrahlung, followed by collisional excitation. The relative significance of collisional excitation is a topic of ongoing discussions (Sanner, 2009). Figure 3 shows a schematic diagram of electron excitation mechanisms such as strong-field excitation. For pulse durations of a few dozen femtoseconds, the free electrons have no time to acquire enough energy for collisional excitation.

On the other hand, avalanche excitation becomes more dominant for increasing pulse duration and laser intensity. The onset of avalanche excitation also depends on the photon energy and bandgap. It could start for near-infrared pulses between a few picoseconds to several picoseconds pulse durations for silica and sapphire (Itina, 2015).

### 2.2. Multiple pulse mechanism in the laser processing

In this research, so far, the discussion

considered only the interaction of single laser pulses at various pulse durations. From single pulses to several pulses (multiple shots), the interaction becomes more complicated due to an increase of essential variables such as the repetition rate (Mirza, 2016). The repetition rate is the frequency of the consecutive pulse, which has a fixed temporal distance. For single pulses, the total energy of the pulse is given by the number of photons within the pulse. With the number of pulses, the total energy incident on the dielectric increases. The consecutive pulses impinge on a highly exciting material with increased temperature. This temperature increase could have already led to material extrusion. The extruding material can interact with the consecutive pulses. The temperature increase could also lead to material modifications, e.g., phase or morphological changes, affecting absorption. The higher ablation rate for multiple pulses results from the incubation effect, which is observed for ultra-short pulses up to 100 and beyond 100 pulses. Due to incubation, the ablation threshold is reduced in the multiple shot regimes (Cheng, 2017). For instance, (Lenzner, 2019) had shown that in fused silica, multiple laser shots reduce the threshold compared to single pulses. Summing up, the incubation effect alters the optical properties of a dielectric material.

### 2.3. Ultra-short pulsed excitation

As shown in figure 4, just like all dielectric materials, ultra-short laser pulses can induce strong-field excitation. Accordingly, Ultra-short pulsed excitation can be classified as follows:

#### 2.3.1 Modeling ultra-short pulsed excitation

Finite-difference and molecular dynamics models have predicted that the ablation threshold and the heat-affected zone are minimized for ultra-short pulses in visible spectra range. (Lenzner, 2019) The damage and ablation threshold can also be determined by theoretical approaches such as molecular dynamic (MD) simulations. MD simulations describe transient atomic interactions and movements by numerically solving Newton's equations of motion for a system of particles. (Baerbel, 2017) The inter-atomic forces and potential energy are defined by molecular mechanics force fields. In general, MD simulations have been utilized in a broad range of scientific work dealing with Short and ultra-short pulsed laser ablation. The MD simulations are limited to microscopic scales in space and time. Thus, MD is not well suited to simulate several pulses or

realistic sample sizes of several tens of micrometers or even larger. These kinds of simulations are covered, for instance, by macroscopic models based on heat equations or rate equations. (Boerner, 2019)

#### 2.3.2 Damage and ablation threshold from pulsed lasers

Due to a lower threshold, it is more efficient to machine visible spectra range with ultra-short pulsed lasers. Another argument for such lasers is that ultra-short pulsed lasers show a reduction in the heat-affected zone compared to longer pulsed lasers. Minimizing the heating of visible spectra range is essential to avoid the phase transition to graphite, which has no apparent high intensity. Visible spectra range is a metastable phase of carbon, which is stable at ambient temperatures, but the phase transition becomes more probable with rising temperatures (Mingareev, 2019). Different phases are also typical in other dielectric materials, but no other dielectrics have such remarkable thermal properties as carbon. For instance, the thermal conductivity of the visible spectra ranges phase is unmatched by any other naturally occurring material. (Chimier, 2011) Most materials with high thermal conductivity are metals, and heat transport is based on the conducting electrons. Heat transport by electrons is not possible in dielectrics, which explains that these materials are, in general, poor conductors. Besides electron thermal conductivity, heat can also be conducted through phonons. Phonons are so-called quasi-particles and describe the elemental or collective excitation of lattice vibrations in solids. Visible spectra range has strong covalent bonding and low phonon scattering, which explains its high lattice thermal conductivity (Sanner, 2009).

#### 2.3.3 Cost and Complexity of Visible Spectra Range

Besides pulse duration, the second key aspect is the wavelength, where shorter wavelengths are better suited to machine visible spectra range. Figure 5 shows that the visible spectra range of laser represented in wavelength. Especially, ultraviolet light is well suited but has some cons on the handling side. First, laser sources emitting at ultraviolet wavelengths have some inherent dangers concerning active laser media. Second, ultraviolet light can harbor risk for human skin depending on the wavelength. Last, such laser light requires special optics, which are suited for these wavelengths and might degrade. In contrast, standard optics are available for visible and near-infrared wavelengths. By default, the

main wavelength is in the spectrum for many types of ultra-short pulsed lasers. Higher harmonic generation provides shorter wavelengths in the visible and ultraviolet spectral range (Stoian, 2018). Naturally, high harmonic generation increases the cost and complexity of the laser system. Again, degeneration of the optics is an issue for the generation of ultraviolet light. In summary, it is desirable to investigate laser processing of visible spectra ranges with a focus on picosecond pulse durations with different wavelengths. Experimental findings are incomplete without a suited model, but a model is also an incomplete image of the reality. (Brown, 2009).

### 2.3.4 Ultra-Short Laser Excitation

Most models describe laser excitation of dielectrics in the femtosecond or nanosecond regime. (Zhdanovich, 2012) Figure 6 shows that ultra-short laser excitation with energy up to 100 MeV for dielectrics in the femtosecond or nanosecond regime. The most investigated materials are silicon, silica, sapphire or materials with similar band gaps. In contrast, visible spectra range is a more exotic material, which is only used if its unique properties are required (Ashkenasi, 2017) (Samad, 2010). For this research paper, only macroscopic models are considered because only such models can describe processes for realistic sample sizes and longer timescales. Such models use statistical quantities such as the temperature to describe melting, vaporization, sublimation, or ablation of small parts of the sample.

## 3. MATERIALS AND METHODS:

The laser-induced damage threshold (LIDT) of optical components is a critical quality parameter for laser systems and their applications operating at high power levels. Furthermore, the LIDT parameter of a material marks the onset of the well-directed laser machining of this material. The determination of this parameter is described in the ISO standards. (Wang, 2004) The basic idea is to shoot a laser pulse with defined pulse energy on the surface and evaluate the irradiated area with a microscope if the surface has been damaged or not. The onset of damage can be determined by successively increasing the pulse energy. Between single pulses, the sample is moved in the focal plane to shoot each pulse at a different position. This procedure is repeated for each pulse energy several times to get statistical information about the occurrence of damage. The event of

damage can also be determined for multiple pulses. The multiple pulse LIDT applies a fixed number of pulses, which are shot on each surface area evaluated in this study.

### 3.1. Ablation threshold - Depth method

The depth regression method considers the vertical distance between the crater bottom and the initial sample surface as a function of the fluence. This depth method is determining the ablation threshold fluence, and thus the results must differ from the previous (damage threshold) methods. (Pietroy, 2012)

The photomicrographs show the morphology induced by a single laser pulse using the maximum pulse energy of the first picosecond laser. The irradiated surface area is arched upward to build a hump. Raman spectroscopy of the hump reveals bands at  $1250\text{ cm}^{-1}$  and  $1580\text{ cm}^{-1}$ , which corresponds to graphite or instead hybridized carbon. In contrast, the purely visible spectra range surface shows a distinct peak located at  $1333\text{ cm}^{-1}$ , indicating hybridized carbon. Such humps have also been observed in other bandgap material such as silicon and attributed to the expansion of molten material that is re-solidified. In this case, the morphological change must not necessarily depend on a previous melting due to meet stability of the visible spectra range. More precisely, visible spectra range converts to graphite in an exothermic reaction. The conversion rate is insignificant at ambient temperature but increases at elevated temperatures. Graphite has a lower density than the visible spectra range, which differs by a factor of 1.56 and supports the development of the hump. Figure 7 shows the visible spectra range generated by a single laser pulse at high pulse energy.

Consequently, the depth regression method can only be applied to multi-pulse experiments. For a few pulses, the graphite humps have also been observed at lower pulse energies. By increasing the pulse energy, the humps start to disappear. The occurrence of humps also goes for more than 50 pulses. This is one reason why this section focuses on the examination of 100 pulses. Another reason is that 100 pulses are almost in the processing regime and, therefore, an average number, which makes it comparable with other studies.

### 3.2. Design and Contraction Visible Spectra Range

Volume regression is another method to determine the ablation threshold. It is not only the

combination of the diameter and depth method but also comprises more information because it considers the depth of every area element. Therefore, volume regression is the most accurate method, but it takes a longer measuring time to evaluate the volume. (Lyu, 2019) Figure 8 shows the flowchart and design for the measured volumes as a function of the laser fluence. The total volume can also be converted to a volume per pulse by division by 100. Within the low fluence domain, all three wavelengths show a linear dependence between ablated volume and the natural logarithm of the fluence. The threshold fluences are determined by interpolating the fit curve to zero-volume.

The ablation efficiency as a function of the laser fluence for different wavelengths. Comparing those wavelengths, UVA has the highest efficiency closely followed by VIS and NIR. The NIR wavelength has its maximum efficiency at approximately  $10 \text{ J cm}^{-2}$ . The efficiency increases monotonically from the threshold fluence to  $10 \text{ J cm}^{-2}$  and then decreases monotonically for increasing fluences. The efficiency curves of VIS and UVA wavelength show similar behavior but reach their maximum at approximately  $5 \text{ J cm}^{-2}$ . Thus, with shorter wavelengths, higher efficiency at lower fluence can be achieved. The efficiency curve has typical curve progression but needs more values between the zero's to maximum ablation efficiency. This is difficult to achieve with single-pulse experiments because the ablation depth has to be larger than the surface roughness. The ablation depth has already been increased by applying multiple pulses. The heat accumulated has been minimized by choosing a repetition rate of a few Hertz. However, it can be assumed that the first pulses change the surface morphology and improve the absorption of consecutive pulses. The machining, measurement, and evaluation is even more simplified by machining pockets. Pockets are more suited to resolve the low fluence domain but result in a decreased ablation threshold due to incubation. Nonetheless, the next section will investigate a single pulse but with femtosecond pulse durations.

### 3.3. Pump and Probe Experiments in Ultra-Fast Phenomena

Pump and probe experiments can be used to obtain information on ultra-fast phenomena. For example, such experimental setups are used to uncover the dynamics of charge carrier transport in semiconductors, chemical reactions or oscillations, and energy transfer in molecules. (Alexeev, 2015) The general measuring principle

is illustrated in figure 9. A sample is hit by a high intensive pump pulse (red beam), which generates an excitation or modification of the sample. After an adjustable time, delay ( $t = x/c$ ), a probe pulse (green beam) hits the sample. The time delay is controlled by an optical delay line (dark gray rectangle) with varying distance  $x/2$ . The reflection or transmission of the probing pulse is measured as a function of the delay.

**Figure 9.** Working principle of the pump (upward) and probe (downward) setup. The downward pulse is delayed by extending the beam path by the time  $n(t)$ . The beam splitter in works in both directions: splitting or combining beam paths.

Usually, the probe pulse has a lower intensity and negligible effect on the excited state. By monitoring the probe signal as a function of the time delay, it is possible to map the dynamic response of the sample. This response can reveal information on the decay of the generated excitation or on other processes initiated by the pump pulse. The temporal resolution is fundamentally limited only by the pulse duration of the pump and probe pulses. In conclusion, the pump and probe technique is a versatile tool with a variety of different setups and applications.

In the following, some details will be described to improve the understanding of the measuring results in the subsequent sections. The pump and probe pulses are generated with the help of a pellicle beam splitter. The beam splitter divides the incident laser pulse into a pump (reflected) and probe (transmitted) pulse — the working principle of a beam splitter. Further, the beam splitter can be used not only for splitting but also for joining beam paths.

In general, the pulse energy of the split pulses depends on the properties of the beam splitter and incident beam. The experimental setup uses the pellicle beam splitter, which divides the incident pulse into equal parts. In contrast, a polarizing beam splitter can be used to reflect s-

polarized and transmit p-polarized parts of a pulse. Waveplates and optical density filters are used to adjust the required polarization and pulse energy, respectively. Another pellicle beam splitter can then rejoin the pump and probe beam path.

### 3.4. Transient Reflectivity in Ultra-Short Laser

Using a 90-fs laser, a high temporal resolution of the transient transmission and reflectivity measurement is achieved. The literature results are depicted the transient reflectivity (a) and transient transmission (b). The transient reflectivity is evaluated with respect to electron-phonon relaxation time. The critical melting flounce of the visible spectra range is according. (a), a pump pulse with  $5.9 \text{ J cm}^{-2}$  is impinging the sample at time zero. This excitation causes the reflectivity to jump from its initial value of 0.2 to 0.4. The jump can be explained by an abrupt increase in the electron density due to strong-field excitation. The maximum reflectivity is almost as high as in the graphite sample. The difference could be attributed to the density difference between the liquefied visible spectra range and HOPG. Between 1 PS and 10 PS, the reflectivity is slowly decreasing from 0.4 to 0.1. This decrease requires a closer look and root cause analysis. Reitze *et al.* explain the reduction in reflectivity by a distortion of the surface optical properties. Furthermore, the misuse is attributed to a release of internal pressure and hydrodynamic expansion of the plasma. Figure 10 shows transient reflectivity and transmission as a function of the pump-probe delay.

Alternative hypotheses explain the reflectivity decrease with fundamental changes (e.g., electron density, scattering rate or refractive index), material removal, scattering due to rapid structural damage, or metal-dielectric transition (reconversion). A reconversion from metal to dielectric is unlikely because the transient transmission does not recover. In contrast, the occurrence of the delayed reflectivity decrease is precisely correlated with the appearance of a damage crater in graphite. The presence of the damage crater suggests that material removal can cause decreasing reflectivity. This argument is reinforced by similar observations in silicon, which shows nearly the same reflectivity values and flounce dependence suggesting a common ablative mechanism. Furthermore, it is excluded that structural or electronic equilibration takes 10 PS to 30 ps. Molecular dynamics simulations show that this equilibration is within 1 PS of heating to the melting temperature.

## 4. RESULTS AND DISCUSSION:

This research investigated ultra-short pulsed laser processing of visible spectra range and related materials. The laser-material interaction is studied theoretically by developing an ultra-short pulsed laser model for visible spectra range. A variety of experiments supplements the modeling and theoretical studies. The experimental examination includes surface analysis for modifications, ablation. Ablation volumes are analyzed for single pulses, multi-pulses, and pockets. Also, transient properties such as ultra-fast changes of the reflectivity are investigated. The experimental and theoretical studies exhibit process parameters and process windows, which can be used as an input parameter for developing a CAD system.

### 4.1. Ultra-Short Laser Types

The simulation results of the models are discussed in this section. The simulation results are compared with the literature and experimental findings. The model is used to investigate several topics such as the impact of the pulse duration and wavelength on the ablation rate. Figure 11 shows the different types of ultra-short laser types with shorter penetration depth and a higher excitation level. Increasing the pulse duration decreases the excitation, and the transient change of the penetration depth starts at a later point in time. This starting point can be represented by the first value of the transient penetration depth below 1 m. The change starts between  $t = 1 \text{ PS}$  and  $t = 400 \text{ fs}$ . This transient change starts earlier in the case of the 700 fs pulses due to the earlier rise of the intensity. Noticeably, the final penetration depth is shorter for 400 fs pulse. The reason for the shorter penetration depth is the higher excitation level, which contrasts with the assumption that shorter pulse duration might accelerate the electrons deeper into the bulk. The MRE model does not consider this effect of high acceleration.

### 4.2. Structural Modeling and Analysis of Design

In general, the total energy of a light pulse can be split into an absorbed, reflected, and transmitted part. Thus, the absorptivity, reflectivity, and transmissivity are determined by the relation:

$$A + R + T = 1 \quad (1)$$

The ideal case for laser machining is  $A = 1$  and thus  $R = T = 0$ . The initial reflectivity is approximately 17 % to 18 % depending on the wavelength, as shown in table 6.1, as well as the

material and surface structure. Thus, the highest possible absorptivity is in the order of 83 % if the transmissivity decreases to zero, and the reflectivity does not change. The reflectivity will rather increase than decrease. Nonetheless, at a certain electron density, the reflectivity has shown a dip. The dip might be interesting in the future to gain the last bit of absorption efficiency. The absorption efficiency might be further increased by using temporal shaped pulses or two consecutive pulses. The idea is to excite a certain electron level so that the reflectivity is decreased and then use this window to deposit the energy of the second pulse or second part of the pulse. The feasibility of such an approach could be investigated by simulation. The simulation will show if such a window is stable enough for energy deposition or if it disappears too fast due to the transient character of the optical parameters. The understanding of ultra-short laser excitation is already deepened by investigating the transient absorptivity of a single Gauss-shaped pulse. First, the transient absorptivity is studied for pulse energy, pulse duration, and wavelength.

#### 4.3. Computer-Aided Design for Ultra-Short Laser

The computer-aided design for ultra-short laser supplements the results of the ultra-short laser model discussed in the methodology sections. The computer-aided design for ultra-short laser uses two coupled heat equations to simulate the electron and phonon temperatures. The phonon temperature is used to predict damage and ablation in the visible spectra range. If the phonon temperature exceeds the modification temperature, the visible spectra range transforms to the ultra-short high-intensity laser.

Graphitization is an exothermic process, and the enthalpy of formation of visible spectra range is released. The enthalpy of formation is considered in the lattice specific heat capacity as a module. If required, the module can be activated, and the graphitization occurs at visible spectra range or, preferably a high-intensity range. Evaluation of high-intensity laser with ultra-short wavelength might be further increased by using temporal shaped pulses or two consecutive pulses in three different cases 0%, 4.5%, and 10.5%, as illustrated in figure 12.

#### 4.4. Wavelength analysis

It is well known that the wavelength has a big influence on the absorption of light. Visible spectra range is transparent for a broad spectral

range between ultraviolet and mid-infrared. In the mid-infrared range, it is possible to excite optical phonons, while direct electronic excitation is only possible in visible spectra range for ultraviolet light. The wavelength analysis concentrates on the transparent range where absorption must have a non-linear character. Figure 13 shows the waveform for the ultra-short high-intensity laser changes of the reflectivity are investigated with time.

### 5. CONCLUSIONS:

The transient reflectivity of visible spectra range increases due to the ultra-fast generation of free electrons (Géneaux, 2019). On a picosecond timescale, the reflectivity decreases below the initial value, which is attributed to the hydrodynamic expansion of plasma. More precisely, the plasma expansion decreases the (electron) density. This changes the refractive index and thus the reflectivity. Therefore, the decrease of the reflectivity is not a relaxation mechanism since the transient transmission does not recover. Morphological and topological surface changes are responsible that the reflectivity does not fully recover for long pump-probe delays.

The experimental results suggest that plasma expansion affects the reflectivity. Different methods are discussed to determine the damage and ablation threshold. In the case of damage, the stochastic method gives the most reliable results. This is similar to (Elishakoff, 1990) conclusions in that the worst-case error shown from the stochastic method is always less than the worst-case error shown from any other spectral manner. The damage threshold decreases with the number of pulses due to incubation. (Harold; 1986) postulates that this denotes irreversible accumulation of permanent material change or irreversible accumulation of long-lived states. More precisely, the damage threshold first decreases and then saturates after a few hundred pulses. The saturation value is the threshold flounce for processes. The wavelength study shows that a frequency doubling from infrared to visible decreases the damage threshold by laser factor. This is equivalent to observations of (Yoshida, 2006). Even lower threshold values can be achieved with laser light of the third harmonic.

*Finally*, it is concluded that

- Ultraviolet laser pulses are best suited to induce damage or modifications to visible spectra range surfaces.

- Additionally, shorter wavelengths have further advantages such as potentially longer Rayleigh lengths and smaller spot sizes.
- Alternatively, the diameter method is used to determine the damage threshold or approximate the ablation threshold.

**RESUMO**

Este artigo examina o estudo do nível de radiação de fundo em Moscou e seu impacto no meio ambiente. Para identificar os efeitos radiológicos nas condições de vida, foi realizado um estudo sobre os efeitos dos nêutrons rápidos na infraestrutura e nos objetos biológicos. Foram consideradas as organizações de pesquisa em larga escala que realizam desenvolvimento tecnológico, pesquisa científica e material utilizando materiais nucleares na cidade de Moscou e na região. O sistema de monitoramento de radiação do meio ambiente, cobrindo uma área de mais de 1091 km<sup>2</sup>, foi examinado em detalhes. Uma pesquisa radioecológica realizada nos distritos administrativos Troitskiy e Novo-Moskovskiy foi analisada para identificar e descrever a situação da radiação. A análise da radiação de fundo em Moscou mostra que os valores dos parâmetros controlados da poluição radioativa de objetos ambientais estão dentro das flutuações de longo prazo do fundo tecnogênico da capital. Nesse caso, surgem vários efeitos térmicos, causados pela exposição à radiação de sólidos. O estudo da infraestrutura e dos objetos biológicos é realizado com base na determinação de efeitos, que resultam em mudança das características elásticas e especialmente plásticas das substâncias expostas à irradiação de nêutrons e aos efeitos térmicos. Nesse caso, os principais fatores importantes são o endurecimento por radiação do material (aumento do limite de extensão gradual) e o inchaço induzido por radiação (aumento da deformação volumétrica).

**Palavras-chave:** *monitoramento radioecológico, dose de radiação absorvida, taxa de dose de exposição, atividade volumétrica de equilíbrio equivalente, carga quasistática.*

**ABSTRACT**

This article discusses the study of the background radiation level in Moscow and its impact on the environment. To identify the radiological impact on living conditions, a study of the effects of fast neutrons on infrastructure and biological objects was made. Large-scale research organizations carrying out technological development, scientific and materials research using nuclear materials in the city of Moscow and the region are considered. A system of environment radiation monitoring, covering an area of more than 1091 km<sup>2</sup>, was examined in detail. A radioecological survey conducted in the Troitsky and Novomoskovsky administrative districts was analyzed to identify and describe the radiation situation. An analysis of background radiation in Moscow

shows that the values of the controlled parameters of radioactive pollution of environmental objects are within the long-term fluctuations of the technogenic background of the capital. In this case, various thermal effects arise caused by radiation exposure to solids. The study of infrastructure and biological objects is carried out based on the determination of effects, because of which the elastic and mainly plastic characteristics of substances exposed to neutron irradiation and thermal effects change. Here, the main essential factors are radiation hardening of the material (increase in yield stress) and radiation swelling (increase in volumetric strain).

**Keywords:** *radioecological monitoring, absorbed radiation dose, exposure dose rate, equilibrium equivalent concentration, quasistatic loading.*

## АННОТАЦИЯ

В данной статье рассматривается исследование уровня радиационного фона в Москве и воздействие его на окружающую среду. Для выявления радиологического воздействия на условия жизни было проведено исследование воздействия быстрых нейтронов на инфраструктуру и биологические объекты. Рассмотрены крупномасштабные научно-исследовательские организации, выполняющие технологические разработки, научные и материаловедческие исследования с использованием ядерных материалов в городе Москве и области. Была детально рассмотрена система радиационного мониторинга окружающей среды, занимающая площадь более 1091 км<sup>2</sup>. Радиоэкологическое обследование, проведенное в Троицком и Ново-Московском административных округах, было проанализировано с целью выявления и описания радиационной обстановки. Анализ фоновой радиации в Москве показывает, что значения контролируемых параметров радиоактивного загрязнения объектов окружающей среды находится в пределах многолетних колебаний техногенного фона столицы. При этом возникают различные тепловые эффекты, которые вызываются радиационным облучением твердых тел. Исследование инфраструктуры и биологических объектов проводится на основе определения эффектов, в результате которых изменяются упругие и особенно пластические характеристики веществ, подверженных воздействию нейтронному облучению и тепловому воздействию. Здесь основными важными факторами являются радиационное упрочнение материала (увеличение предела текучести) и радиационное разбухание (увеличение объемной деформации).

**Ключевые слова:** *радиоэкологический мониторинг, поглощённая доза облучения, мощность экспозиционной дозы, эквивалентная равновесная объемная активность, квазистатические нагружения.*

## 1. INTRODUCTION

In recent years, the radiation situation on Earth has undergone significant changes. As a result of numerous ground atomic testings, the radioactivity build-up occurred (Sean Hubar, 2017; Cuttler, 2019; Huang *et al.*, 2020; Inoue *et al.*, 2020). 12.5 tons of fission products were thrown into the biosphere (Pant *et al.*, 2018; Saha *et al.*, 2019; Orlov *et al.*, 2003; Skvortsov *et al.*, 2014; Litvishko *et al.*, 2020; Mietelski and Povinec, 2020). All explosions from atmospheric nuclear tests changed the equilibrium content of tritium by almost 100 times and by 2.6% to equilibrium content of carbon-14, which led to an excess of the natural background radiation by 2% (Aleikin *et al.*, 2019; Pivovarov and Mikhalev, 2004; Chubirko *et al.*, 2019; Tushavina *et al.*, 2019; Yakovlev *et al.*, 2020; Dridi *et al.*, 2020).

The accident at the Chernobyl nuclear power plant led to the release of 15 tons of radioactive substances into the biosphere.

However, the danger of nuclear fuel cycle facilities is not only in the field of accidents and disasters (Rabi *et al.*, 2017; Ali *et al.*, 2018; Renaud *et al.*, 2020). Even without them, about 250 radioactive isotopes fall into the environment as a result of the nuclear facilities operation (Kuznetsov, 2003; Tushavina *et al.*, 2019; Topchy, 2018; Kuznetsov *et al.*, 2019). One of the most acute problems in the world is the problem of radioactive waste (Prister *et al.*, 2018; Umbetov *et al.*, 2016; Yudaev *et al.*, 2019; Carlberg *et al.*, 2019; Taleyarkhan, 2020). In 1994, 554 "lost" or unauthorized dumping sites of ionizing radiation sources in Moscow, St. Petersburg, Bratsk, Volgograd, and hundreds in other territories were identified in Russia. Thus, the highest levels of pollution were found in St. Petersburg (> 40 R/h) and Cherepovets (> 2 R/h) (Zverev, 2010; Okhrimenko *et al.*, 2017; Shugurov and Knyazyuk, 2018; Umbetov *et al.*, 2017; Trotsenko *et al.*, 2019).

On the territory of Moscow, in the course of scrupulous surveys carried out after the Chernobyl events, up to 80 places of unregistered "burial

sites" of used radionuclides were found. In general, over ten years after the accident, up to 600 "mortuaries" of this kind were liquidated (Kuznetsov, 2003; Mikayilova, 2017). Moscow is the only capital of the world where on December 25, 1946, the first reactor on the European continent was launched. The city also has large research organizations that carry out technological developments, scientific and materials research using nuclear materials. This is the Russian Scientific Centre "Kurchatov Institute" since 1943, the State Scientific Center High-Tech Research Institute of Inorganic Materials named after Academician A.A. Bochvar since 1945, ARRICT since 1951. Therefore, our work aimed to examine the city of Moscow to determine the radiation situation, as well as to study the behavior of various bodies and biological objects under the influence of neutron and thermal radiation.

The study of infrastructure and biological objects is carried out based on the determination of effects, as a result of which the elastic and mainly plastic characteristics of substances exposed to neutron irradiation and thermal effects change (Liu and Wu, 2018; Bulavin *et al.*, 2018; Lazarenko *et al.*, 2018; Forkapić *et al.*, 2019; Chao *et al.*, 2020). Here, the main essential factors are radiation hardening of the material (increase in yield stress) and radiation swelling (increase in volumetric strain).

In this work, the radiation exposure to solids, which is accompanied by numerous thermal effects, as a result of which additional volumetric strain  $\theta_1$  arises in them, and elastic and mainly plastic characteristics of the substance change was studied.

## 2. MATERIALS AND METHODS

The system of radioecological monitoring in Moscow covers the entire territory of the city ( $> 1091 \text{ km}^2$ ) and consists of stationary and mobile means of monitoring, the central laboratory complex, and the information-analytical center. Because of the research, a methodology for studying the stress-strain state of elastoplastic bodies and biological objects under cyclic loading in neutron and heat fluxes is proposed. To study the radiation exposure of solid materials, which is accompanied by numerous thermal effects, were chosen isotropic materials based on aluminum and steel. It was believed that neutrons fall with the same average energy and intensity. The temperature field was assumed to be constant. The kinematic and dynamic parameters of elastoplastic bodies in a neutron flux, taking into

account thermal effects, were determined on the basis of the methods of the dynamic theory of elastoplastic bodies (Taleyarkhan, 2020).

Consider an initial homogeneous isotropic body occupying the half-space  $z \geq 0$ . The half-space is affected by the neutron flux and the temperature field (Figure 1). If neutrons with the same average energy and intensity  $\varphi_0$ , neutron/( $\text{m}^2\text{sec}$ ) are incident on the boundary ( $z = 0$ ) parallel to the  $z$ -axis, then the intensity of the neutron flux reaching the plane  $z = \text{const}$  will be Equation 1 (Starovoitov *et al.*, 2009). The temperature field is assumed to be constant and determined by the function  $\Delta T$ . The quantity  $\mu$  in (1) is called the macroscopic cross-section and is of the order of  $1/\text{m}$ . For any chemical element, it is calculated by Equation 2 (Starovoitov *et al.*, 2009), where  $\sigma$  is the cross-section assigned to one core,  $n_0$  is the number of cores per  $1 \text{ cm}^3$ ,  $A_0$  is the Avogadro's number,  $\rho$  is the density,  $A$  is the atomic weight.

As an example, aluminum  $\sigma = 0.21 \cdot 10^{-24} \text{ cm}^2$ ,  $A_0 = 6.022 \cdot 10^{23} \text{ mol}^{-1}$  density  $\rho = 2.7 \text{ g/cm}^3$ ,  $A = 27$  dalton was considered. Substituting these values in Equation 2,  $\mu = 1,26 \text{ m}^{-1}$  was obtained. If  $\varphi_0$  is constant, then by the time  $t$ , a flux will pass through section  $z$  (Equation 3). In a rough approximation, it can be assumed that the change in the volume of a substance is directly proportional to the flux  $I(z)$  and, therefore (Equation 4), where  $B$  is the experimental constant. Value (Equation 5) gives the total neutron flux per unit surface area of the body. In reactors,  $\varphi_0$  is of the order of  $10^{17}$ – $10^{18}$  neutrons/( $\text{m}^2\text{sec}$ ), and  $I_0$  reaches  $10^{23}$ – $10^{27}$  neutrons/( $\text{m}^2\text{sec}$ ), with  $\theta_1$  being of the order of 0.1. Therefore, depending on the energy of neutrons and the irradiated material, the value of  $B$  can be of the order of  $10^{-28}$ – $10^{-24} \text{ m}^2/\text{neutron}$  (Starovoitov *et al.*, 2009).

The dependences of the elasticity modulus, yield stress and ultimate stress limit, and the entire stress-strain diagram on  $I_0$  for various energies were studied experimentally after irradiation of the samples in atomic reactors. For massive bodies with a flat boundary, the number of neutrons passing at a depth  $z$  below this boundary in time  $t$  is determined by Equation 3. Therefore, the yield stress will be variable in thickness  $z$ . On the body surface ( $z = 0$ ), the effect of radiation on the plasticity limit  $\sigma_y$  is quite satisfactorily described by the equation of radiation hardening (Equation 6) (Starovoitov *et al.*, 2009), where  $\sigma_{y0}$  is the plasticity limit of unirradiated material, where the neutron flux value  $I(z)$  is described by Equation

**Erro! Fonte de referência não encontrada.**;  $A, \xi$  are the constants of the material obtained from the experiment.

### 3. RESULTS AND DISCUSSION:

Let's consider the process of effects of external forces and radiation flux on a deformable body within the framework of the theory of small elastoplastic strains. Suppose that at the initial moment, a body in a natural state is immediately affected by external forces  $F_i'$ ,  $R_i'$  at interface displacement  $u_{i0}'$ , and at the same time a neutron flux of  $I_0 = \varphi_0 t$  is incident on its surface. It is assumed that under such an impact, areas of elastic and plastic strains appear in the body. The change in the elastic moduli due to neutron irradiation was neglected. The stresses, strains, and displacements arising in the body are marked with one stroke at the top.

For example, if for aluminum alloy 356,  $A = 1.09$ ;  $m^2/\text{neutron}$  was taken, then satisfaction with known experimental data can be judged by Figure 2. Dark points – experiment, solid line – calculation by equation (6). The corresponding deformation values are denoted by  $\varepsilon_{y0}$ ,  $\varepsilon_y$ .

In the elastic regions of a solid body, Hooke's law is valid, and the well-known relations between the stress deviators and strain deviators  $s'_{ij}$ ,  $\varepsilon'_{ij}$ , and their spherical parts  $\sigma'$ ,  $\varepsilon'$  corrected for additional volumetric strain due to the influence of  $B/I$  neutron irradiation and thermal effects  $\Delta T$  are fulfilled (Equation 7), where  $G$  is the modulus of elasticity in shear,  $K$  is the volumetric strain modulus,  $\alpha$  is the linear expansion coefficient of the material,  $\Delta T$  is the temperature change.

For those areas of the solid body where plastic strains appeared, the connection of deviators in the case of simple loading can be represented as (Equation 8), where  $f'(\varepsilon'_u, I, a'_k)$  is the plasticity function, which depends on the strain intensity  $\varepsilon'_u$ , the magnitude of the neutron flux  $I$  and the approximation parameters  $a'_k$ .

With a sufficiently fast "instantaneous" application of the power load, the hardening effect of radiation will not have time to affect, and the resulting areas of plastic strain will be the same as without the influence of the neutron flux. Under slow active loading, the outer layers of the body will become hardened over time, and the areas of plastic strain in them may turn out to be less or absent altogether, compared with an unirradiated body. In its effect on elastoplastic bodies, radiation

exposure is opposite to thermal, which reduces the yield stress and leads to an increase in plastic strain zones at the same loads (Figure 3).

To relations (Equation 8), differential equations of equilibrium, Cauchy equations, and boundary conditions under the assumption of small deformations was added (Equations 9-10). The comma in the subscript indicates the differentiation operation by the coordinate following it. Changes in the time of external loads and interface displacements occur in such a way that the corresponding loading paths do not belong to the class of substantially complex loads, and radiation hardening and thermal action occur after the forced strain of a solid body.

Let, starting from time  $t_1$ , the influence of the neutron flux ceases ( $\varphi = 0$ ), and the external forces change in such a way that unloading and subsequent alternating loading with bulk  $F_i''$  and surface forces  $R_i''$  (on  $S_\sigma$ ) occur at all points of plastically deformable regions of the body  $V_p'$  at the interface displacement  $u_{i0}''$  (on  $S_u$ ). The level of exposure to the body remains constant and equal to its value before unloading (Equation 11).

The plasticity limit at points of the body depends on the  $z$  coordinate and becomes equal to  $\sigma_y''(I_1(z))$ , that is, it depends on the magnitude of the strain and radiation hardening (Figure 3). Following (Starovoitov *et al.*, 2019), one can determine the kinematic and dynamic parameters of elastoplastic bodies in a neutron flux, taking into account the thermal effects. For this, as an example, the problem of repeated radiation-force bending of a three-layer cantilever beam under the influence of a temperature field was considered.

For the three-layer beam, which is asymmetric in thickness, the hypotheses of a broken normal are accepted: Kirchhoff hypothesis is valid in the base layers, the normal remains straight in the filler, does not change its length, but rotates by some additional angle  $\psi(x)$ . Let the outer base layers of the beam be made of metal and the inner layer (filler) incompressible in thickness – from polymer. The base layers are accepted as elastoplastic, and the filler is nonlinearly elastic. An analytical solution to the corresponding problem of the elasticity theory is given in (Gorshkov *et al.*, 2005). The study of thermal processes in various media is described in (Rabinskii and Tushavina, 2019; Rabinskiy and Tushavina, 2019a; Rabinskiy and Tushavina, 2019b; Starovoitov and Leonenko, 2019; Rabinskiy *et al.*, 2019; Astapov *et al.*, 2019; Antufev *et al.*, 2019; Rabinsky and Kuznetsova, 2019; Makarenko and Kuznetsova, 2019).

Let to the outer surface (Equation 12) of the considered three-layer beam, in addition to the distributed power load,  $p(x), q(x)$  a neutron flux of density  $\varphi_0$  is supplied in the direction opposite to the external normal and the temperature field (Figure 4). To describe the deformation of layer materials in a neutron flux, equations of state of type (Equation 8) was used (Equation 13), where  $f^{(k)}$  is the universal function of nonlinearity at loading from a natural state (Equation 14)  $\omega^{(k)}(\varepsilon_u^{(k)}, I)$  in the base layers, the plasticity function of Ilyushin is used, in the filler – the function of nonlinearity.

In the future, it will be assumed that changes in time of external loads and interface displacements occur in such a way that the corresponding loading paths do not belong to the class of essentially complex loads. Also, the radiation growth in the plasticity limit does not exceed the growth in the strain intensity at the irradiated points of the solid body, which would prevent the formation of plastic strains.

The considered problem of loading from a natural state was solved by the method of linear approximation (Gorshkov *et al.*, 2005). In our case, following relations (Equation 14) (under the influence of a neutron flux and a temperature field), the solution was obtained by the same method. As a result, the desired strains are determined by the following recurrence equations ( $n$  is the approximation number) (Equation 15). Here,  $p_\omega^{(n-1)}, h_\omega^{(n-1)}, q_\omega^{(n-1)}$  additional “external” loads serve as corrections for the plasticity and physical nonlinearity of the materials of the layers under repeated loading and take into account the effect of the neutron flux and temperature. They are taken equal to zero at the first step ( $n = 1$ ), and further calculated by the results of the previous approximation, the fourth-order function  $g^{(n)}(x)$ , coefficients  $\alpha_1, \alpha_2, \alpha_3, \beta^2, \gamma_1, \gamma_2, \gamma_3$ , and linear integral operators  $L_2^{-1}, L_3^{-1}, L_4^{-1}$  are defined in (Gorshkov *et al.*, 2005). Integration constants  $C_1^{(n)}, \dots, C_8^{(n)}$  take into account the effects of neutron and heat fluxes. In the case of a *rigid cantilever termination* of the left end of the rod with a free right, satisfying the boundary conditions, was obtained (Equation 16).

With repeated alternating loading, the recurrent solution for quantities with asterisks will be similar (Equation 16) (Equation 17). Numerical results were obtained for a three-layer beam, the layers of which are made of D16T – fluoroplastic –

D16T. Relative layer thicknesses:  $h_1 = h_2 = 0.03$ ,  $c=0.09$ . The mechanical and radiation parameters of the layer materials included in the equation (16) are given in (Gorshkov *et al.*, 2005; Tushavina *et al.*, 2019). In addition, it was taken:  $B = 10^{-23}$  m<sup>2</sup>/neutron, which ensures a volumetric strain of 3–3.5% in the layers of the considered rod,  $\mu = 1.26$  cm for duralumin, and  $\mu = 3.21$  cm for fluoroplastic.

Figure 5 shows the change in the deflection  $w - a$  along the axis of the three-layer rod under consideration, calculated according to various physical equations of state with cantilever restraint of the left end. Curves with one stroke correspond to loading from the natural state: 1, 2 – elastic and elastoplastic rods without irradiation, 3 – elastoplastic rods at  $\varphi = 10^{18}$  neutron/(m<sup>2</sup>s) and  $\Delta T = 300$  K. With repeated loading, the displacements decrease by 2–3%, both for unirradiated and irradiated rods, which is explained by the cyclic hardening of the material with each change in the sign of the load. On each half-cycle, the conditions of simple loading at small strains are satisfied.

#### 4. CONCLUSIONS:

It is shown that the maximum level of neutron irradiation can cause loosening of the substance, and the heat flux is harmful to biological objects. Calculations show that the impact of the radiation situation slightly affects the stress-strain state of elastoplastic bodies and biological objects. In this case, the action of the temperature field significantly affects the kinematic and static parameters of the objects.

A method for studying the stress-strain state of elastoplastic bodies under cyclic loading of a neutron flux is proposed, which significantly simplifies the solution of a whole class of boundary value problems. The mathematical model presented in the work has restrictions on the maximum level of neutron irradiation, which should not cause loosening of the substance. In this case, on each half-cycle, the conditions of simple loading and deformation must be satisfied.

### RESUMO

Os métodos existentes para estudar o estado termicamente deformado e tenso de uma haste de comprimento limitado feita de liga especial resistente ao calor não levam em conta a presença simultânea de processos térmicos, como transferência de calor, força axial, isolamento térmico, temperatura local, condições operacionais da haste e o fato, que em larga escala o coeficiente de expansão térmica do material da haste depende de temperatura. Para resolver esses problemas, os autores propõem um novo método numérico para estudar o estado termomecânico de uma haste de comprimento limitado feita da liga resistente ao calor ANV-300. Esta haste é de comprimento limitado e rigidamente comprimida com duas extremidades. A superfície lateral das seções  $(0 \leq x \leq L/3)$  e  $(2L/3 \leq x \leq L)$  o núcleo são isolados termicamente. No local  $(L/3 \leq x \leq 2L/3)$  da haste, é fornecida a temperatura local, que varia em coordenada por uma lei linear. Os estudos foram realizados em diferentes temperaturas ambientes. Os padrões da distribuição do campo de deslocamentos elásticos do componente elástico da deformação são construídos de acordo com a lei de Hooke, com os valores do componente elástico da tensão e levando em consideração a dependência do campo entre o coeficiente de expansão térmica e temperatura. Como resultado do estudo, verificou-se que uma mudança na temperatura da área transversal da extremidade esquerda do ambiente tem um efeito menor no estado de tensão térmica da haste considerada do que o efeito da mudança.

### ABSTRACT

Existing methods for studying the thermally stressed and deformed state of a rod of the limited length from a special heat-resistant alloy do not take into account the simultaneous presence of thermal processes, such as heat exchange, axial force, thermal insulation, local temperature, operating conditions of the rod and the full-scale dependence of the coefficient of thermal expansion of the material of the rod on temperature. To solve such problems, the authors propose a new numerical method for studying the thermomechanical state of a rod of the limited length from the heat-resistant alloy ANV-300. This rod is of a limited length and rigidly clamped at both ends. The lateral surface of sections  $(0 \leq x \leq L/3)$  and  $(2L/3 \leq x \leq L)$  of the rod is thermally insulated. At the site  $(L/3 \leq x \leq 2L/3)$  of the rod, the local temperature is given, which varies in coordinate by a linear law. The studies were carried out at different ambient temperatures. The laws of the distribution field of elastic displacements of the elastic component of deformation are constructed, respectively, according to Hooke's law, the values of the elastic component of stress, taking into account the field dependence between the coefficient of thermal expansion and temperature. As a result of studies, it was found that a change in the temperature of the

surrounding cross-sectional area of the left end of the medium has little effect on the thermally stressed state of the considered rod than the effect of the change.

## АННОТАЦИЯ

Существующие методы исследования термически напряженного и деформированного состояния стержня ограниченной длины из специального жаропрочного сплава не учитывают одновременное наличие тепловых процессов, таких как теплообмен, осевая сила, теплоизоляция, локальная температура, условия эксплуатации стержня и натурная зависимость коэффициента теплового расширения материала стержня от температуры. В статье на основе минимизаций потенциальной энергии упругих деформаций с применением метода квадратичного конечного элемента с тремя узлами разработана математическая модель термонапряженно-деформированного состояния горизонтального стержня из жаропрочного сплава АНВ-300. Данный стержень ограниченной длины и жестко зашпелен с двумя концами. Боковая поверхность участков  $(0 \leq x \leq L/3)$  и  $(2L/3 \leq x \leq L)$  стержня теплоизолированная. На участке  $(L/3 \leq x \leq 2L/3)$  стержня дана локальная температура, меняющаяся по координате линейным законом. Через площадь поперечных сечений обоих концов данного стержня происходит тепловой обмен с окружающими их средами. Закономерности распределения поля упругих смещений упругой составляющей деформации строятся в соответствии с законом Гука, значениями упругой составляющей напряжений с учетом полевой зависимости между коэффициентом теплового расширения и температурой. В результате исследования было установлено, что изменение температуры окружающей площади поперечного сечения левого конца среды оказывает меньшее влияние на термически напряженное состояние рассматриваемого стержня, чем влияние изменения.

**Ключевые слова:** *минимизация потенциальной энергии, метод конечных элементов, теплоизоляция, температура, коэффициент теплообмена.*

## 1. INTRODUCTION

The influence of ambient temperature on the thermally stressed state of a rod of this alloy in the presence of local temperature is carried out, and numerical results of the study are presented. Ambient temperature affects the rod through the cross-section of the left end. The studies were carried out at different ambient temperatures. The laws of the distribution field of elastic displacements of the elastic component of deformation are constructed, respectively, according to Hooke's law, the values of the elastic component of stress, taking into account the field dependence between the coefficient of thermal expansion and temperature. As a result of studies, it was found that a change in the temperature of the surrounding cross-sectional area of the left end of the medium has little effect on the thermally stressed state of the considered rod than the effect of the change. Thus, only by changing the value (and not), i.e., by changing the environmental properties of the surrounding cross-sectional area where heat transfer occurs, the thermally stressed state of the rod under investigation can be changed.

Existing methods for studying the thermally stressed and deformed state of a rod of the limited

length from a special heat-resistant alloy do not take into account the simultaneous presence of thermal processes, such as heat exchange, axial force, thermal insulation, local temperature, operating conditions of the rod and the full-scale dependence of the coefficient of thermal expansion of the material of the rod on temperature (Geng *et al.*, 2018; Kudaykulov *et al.*, 2019; Litvishko *et al.*, 2020; Shen *et al.*, 2019). To solve such problems, the authors propose a new numerical method for studying the thermomechanical state of a rod of the limited length from the heat-resistant alloy ANV-300, which allows one to take into account the dependence between the coefficient of thermal expansion and the field of temperature distribution, operating conditions, and fixing. Chemical composition in % for grade ANV-300: C (max 0.1), Si (max 0.5), Mn (max 0.5), Ni (64.2-70.1), S (max 0.01), P (max 0.015), Cr (14-17), W (7-10), Ti (1.4-2), Al (4.5-5.5), B (max 0.1), Ni – basis. It is used for the manufacture of ingots and cast rods intended for further remelting in the manufacture of shaped castings.

The determining fundamental relations of thermoelasticity of weakly compressible materials are considered in (Mikhlin, 1974; Lee *et al.*, 2017; Pandiyan *et al.*, 2019; Rabinskiy and Tushavina,

2019; Dmitriev *et al.*, 2011; Kolokoltsev *et al.*, 2020). Using a small parameter, an analytical solution to the problem of stretching a rod from a weakly compressible material under nonisothermal conditions is obtained. In (Nozdrev, 1967; Fedotov *et al.*, 2018; Starovoitov *et al.*, 2016; Qiu *et al.*, 2017; Bartels, 2019; Krechetov *et al.*, 2018; Civallek *et al.*, 2020), the basic problems of thermodynamics and their application are described in sufficient detail. Zenkevich (1975) is devoted to the presentation of the finite element method, as one of the most effective methods for the numerical solution of engineering, physical and mathematical problems using computers. In (Timoshenko and Goodyear, 1975; Chen *et al.*, 2017; Park *et al.*, 2019; Hou and Gao, 2020; Santos *et al.*, 2020), a systematic presentation of the theory of elasticity was given, starting with the derivation of the main relations and ending with some solutions obtained in recent years. The plane problem, the problem of torsion and stress concentration, some spatial problems, variational principles, and methods for solving problems are considered in detail.

Based on energy principles in combination with the use of a finite quadratic element with three nodes, a mathematical model, a computational algorithm, and a set of applied programs were developed in (Kudaykulov, 2009; Kudaykulov *et al.*, 2009; Formalev *et al.*, 2019; Formalev and Kolesnik, 2019; Myrzasheva and Shazhdekeyeva, 2015; Myrzasheva *et al.*, 2016; Akhmetov and Kudaykulov, 2017; Myrzasheva *et al.*, 2018; Deepa and Rajendran, 2018; Kuznetsova and Rabinskiy, 2019). With the help of these developments, the problems of determining the thermomechanical and thermo-stress-strain states of a rod of constant cross-section, depending on the presence of local thermal insulation, temperature, heat transfer, and their operating condition, are numerically solved. The mechanical properties of heat-resistant steels and alloys at room and high temperatures, the influence of alloying elements on the structure, and methods of thermal and hot processing of alloys are considered in (Himushin, 1969). Also considered are heat-resistant alloys on iron, nickel, cobalt bases, and several refractory metals and their alloys. The most important methods and techniques of computational mathematics are described in (Demidovich and Maron, 1960; Yano *et al.*, 2018; Leon and Chen (Roger), 2019; Sun *et al.*, 2020).

At present, in our republic and abroad, there are many scientific works devoted to the problem of determining the dependence of the

thermally stressed-deformed state of bar elements of complex construction. Of these works, scientific studies by scientists of our country and neighboring countries can be noted: A.K. Kudaykulov (2009), B.B. Orazbaev (Orazbaev *et al.*, 2017), M.M. Ermekov (2011), V.V. Afanasyeva (Afanasyeva and Lazerson, 1995), V.N. Bakulin (1985), I.A. Birger (1992), G.S. Pisarenko (Pisarenko *et al.*, 1973), A.I. Oleinikov (Korobeinikov *et al.*, 2008), Yu.A. Fedorov (2001), F.F. Himushin (1969) and others, as well as foreign scientists, like O. Zenkevich (1975), F. Krieth (1973), V.F. Nozdrev (1967), L. Segerlind (1979) and others.

## 2. MATERIALS AND METHODS

Consider a rod of limited length  $L, (cm)$  made of the heat-resistant alloy ANV-300. Both ends of the shaft are rigidly pinched. The cross-sectional area of the rod is  $F, (cm^2)$ , which is constant over its entire length. The thermal expansion coefficient of the rod material  $\alpha(T), (1/^\circ K)$  depends on the field temperature distribution. The thermal conductivity coefficient of the rod material is  $K_{xx}, \left(\frac{watt}{cm \cdot ^\circ K}\right)$ , the elastic modulus is  $E, \left(\frac{kG}{cm^2}\right)$ . The elastic modulus of the heat-resistant alloy ANV-300 is temperature independent. Through the cross-sectional areas of the two pinched ends of the rod, heat exchange occurs with their surroundings. For the left end of the rod ( $x = 0$ ), the heat transfer coefficient is denoted by  $h_0, \left(\frac{watt}{cm^2 \cdot ^\circ K}\right)$ , and the ambient temperature by  $T_{amb\ 0}, (^\circ K)$ . Similarly, for the right end ( $x = L$ ) –  $h_L, \left(\frac{watt}{cm^2 \cdot ^\circ K}\right)$  and  $T_{amb\ L}, (^\circ K)$ . Side surfaces, which are  $\frac{1}{3}$  of the length of the rod, i.e.,  $(0 \leq x \leq (L/3))$  and  $((2L/3) \leq x \leq L)$  we consider the core to be thermally insulated. In the area of the rod  $((L/3) \leq x \leq (2L/3))$ , the local temperature is given. It can be constant, varying along the local length of the rod with linear and quadratic laws.

In the presence of heat sources due to thermal expansion and pinching, a stress-strain state appears in the inner sections of the rod. In this case, the components of the deformation and stress will be respectively, elastic  $(\varepsilon_x, \sigma_x)$ , temperature  $(\varepsilon_T, \sigma_T)$  and thermoelastic  $(\varepsilon, \sigma)$ . If the field shows the temperature distribution and

thermal expansion coefficient along the length of the rod, then the expression of the function that characterizes the potential energy of elastic deformations of the considered rod has the following form (Equation 1), where  $V$  is the volume of the rod; Equation 2 is component of elastic deformation; Equation 3 is the field of elastic displacement along the length of the rod; Equation 4 is elastic component of stress; Equation 5 is the law distribution of the coefficient of thermal expansion along the length of the rod;  $E$  – module of elasticity of the core material; Equation 6 is law temperature distribution along the length of the rod.

To construct a mathematical model of the thermal stress state of a heat-resistant alloy rod pinched by two ends, we discretize it by quadratic elements with three nodes. Given that the process under consideration is a steady-state, within each discrete element, the field distribution of temperature, coefficient of thermal expansion and elastic displacement is approximated by a full second-order polynomial passing through three nodal points  $i, j$  and  $k$  (the length of the discrete element is  $\lambda$ , starting point  $i$ , mid- $j$ , and finite- $k$  and  $x_i = 0$ , Equations (7)-(8)). Within each discrete field element, the distribution of these functions is expressed by the following Equations (9)-(11) (Mikhlin, 1974; Nozdrev, 1967; Zenkevich, 1975). Where  $T_i, T_j, T_k$  are the values of  $T(x)$  the nodal points  $i, j, k$ ;  $u_i, u_j, u_k$  are the displacements of the sections along the coordinate, which are the coordinates of the nodes  $i, j, k$ , respectively;  $\alpha_i, \alpha_j, \alpha_k$  are values of  $\alpha(T(x))$  at these nodal points, respectively, in the interval  $x \in (x_i \leq x \leq x_k)$ ;  $\gamma_i(x), \gamma_j(x)$  and  $\gamma_k(x)$  are the form functions for a quadratic element with three nodes, where (Equation 12).

The properties of these forms functions will ensure the continuity of the desired functions during the transition from one element to the next. For this case, the expression of the functional characterizing the potential energy of elastic deformation, in the presence of heat sources for one discrete element, has the following form (Equation 13). Where  $V_i$  is the volume of the discrete quadratic element under consideration with three nodes. Then the potential energy of elastic deformation of the entire rod in the presence of heat sources expressed as Equation 14. Where NDE is the number of discrete elements in the rod (Zenkevich, 1975; Timoshenko and

Goodyear, 1975; Kudaykulov, 2009; Kudaykulov *et al.*, 2009).

Considering each integral in expression (Equation 13) separately and from (Equation 12), finding the expression for partial derivatives  $\frac{\partial \gamma_i}{\partial x}, \frac{\partial \gamma_j}{\partial x}, \frac{\partial \gamma_k}{\partial x}$ , and substituting them in Equation 13, we obtain an integrated expression of the function that characterizes the potential energy of elastic deformation of a discrete element in the presence of a temperature field (Equation 15). Further, minimizing the last functional concerning the nodal values of elastic displacement, we obtain a mathematical model of the thermally stressed state of a discrete element in the form of resolving systems of linear algebraic equations for the movement of element nodes (Equations 16-18).

These equations are obtained for nodes of one discrete element. Since we discretize the considered rod with a set of quadratic elements with three nodes, the expression for the functional of the potential energy of elastic deformation should be written for each element, taking into account the temperature field (Zenkevich, 1975; Myrzasheva and Shazhdekeyeva, 2015). Then, the general expression of potential energy for the considered rod as a whole has the form (Equation 14). The total number of nodes will be equal  $2 \times nn + 1$ . In the general case, the mathematical system of the thermally stressed state of the considered rod pinched by two ends is the following system of linear algebraic  $2 \times nn + 1$  equation (19), where  $i$  is presented in the Equation 20. The displacement values of the two ends of the rod (due to rigid pinching) are equal to  $u_1 = u_{2 \times nn + 1} = 0$ .

Solving system (Equation 19), the nodal values of elastic displacements are determined. The values of the elastic component of the deformation in the first half of the element are determined as Equation 21. Similarly, for the second half of the element, we have (Equation 22). Accordingly, according to Hooke's law, the values of the elastic component of stress are determined as follows (Equation 23). The values of the temperature component of the deformation and stress are determined as follows (Equations 24-25). When  $\varepsilon_x^I; \varepsilon_x^{II}; \varepsilon_T^I; \varepsilon_T^{II}; \sigma_x^I; \sigma_x^{II}; \sigma_T^I; \sigma_T^{II}$  are known, values of thermoelastic strain and stress components are determined (Equations 26-27).

Based on the developed mathematical model, we will carry out a numerical simulation of the thermally stressed state of the considered rod in dependence  $T_{amb}$ , for fixed values of all other

parameters. The core works in the presence of heat transfer, thermal insulation, and temperature. The temperature varies along the local length of the rod by a linear law, i.e., (Equation 28) at  $((L/3) \leq x \leq (2L/3))$ , where (Equation 29). We coordinate the coordinate axis  $Ox$  from left to right (Figure 1). It is required to study the thermal stress state of a rod made of heat-resistant alloy ANV-300 clamped at both ends, depending on, for fixed values of all other parameters. Task. The values of the necessary parameters are as follows:

$$T_{amb\ 0} = T_{amb\ L} = 40\ (^{\circ}K) \cdot a = 40; \quad L = 30\ (cm);$$

$$T = 40x; \text{ Equations (30)-(32) at } 10 \leq x \leq 20\ (cm).$$

We vary the value of the ambient temperature with the cross-sectional area of the left end ( $x = 0$ ) of the rod:  $T_{amb\ 0} = 10\ (^{\circ}K); 20\ (^{\circ}K); 30\ (^{\circ}K); 40\ (^{\circ}K)$ .

As mentioned above, in the presence of the given heat sources and partial thermal insulation, the rod tries to expand. However, due to the pinching of both ends, compressive forces  $R$  appear. In this regard, and due to the inhomogeneous temperature field, an inhomogeneous stress field arises in the inner sections of the rod. Components of the strain will be  $\varepsilon_x, \varepsilon_T, \varepsilon$ , and stresses  $\sigma_x, \sigma_T, \sigma$ . It is required to determine the displacement field (Equation 33), elastic deformations  $\varepsilon_x$ , temperature deformations  $\varepsilon_T$ , thermoelastic deformations  $\varepsilon$ , as well as elastic, temperature, and thermoelastic stresses  $\sigma_x, \sigma_T$  and  $\sigma$ .

To solve this problem, the considered rod is discretized  $n=150$  by quadratic elements with three nodes. Then the length of each element will be  $\Delta l = 0.2\ cm$ . For each discrete element, an expression is written of the functional of the potential energy of elastic deformation, taking into account the presence of a temperature field. Next, summing them overall discrete elements, we find the expression of the corresponding functions for the considered rod as a whole. The total number of equations in the system will be  $2n+1=301$ . Since both ends of the rod are rigidly pinched, then  $u_1 = u_{301} = 0$ . In this regard, the number of equations in the system will be 299. By minimizing the potential energy of elastic deformation, taking into account the presence of a local field of temperature distribution and heat exchanges, we obtain (Equation 19), a system of resolving equations.

Moreover, if the number of discrete elements in the rod is  $n$  (where  $n$  is a positive

integer), then the number of nodes in the rod will be  $2n+1$ . Nevertheless, since both ends of the rod are rigidly clamped, the movement of the extreme nodes will be zero, i.e.  $u_1 = u_{2n+1} = 0$ . Therefore, the minimization of the functional characterizing the potential energy of elastic deformations in the presence of a temperature field is minimized by nodal displacements (Equation 34). Solving the last system, we find the nodal values of displacement. Further, according to (Equations 21-27), the value of the components  $\varepsilon_x, \varepsilon_T, \varepsilon$   $\sigma_x, \sigma_T, \sigma$  in the given sections of the rod are determined. The task (Equation 35) is accepted (Myrzasheva *et al.*, 2016; Akhmetov and Kudaykulov, 2017).

### 3. RESULTS AND DISCUSSION:

To obtain the results of the problem, first it was considered the case when  $T_{amb\ 0} = 10\ (^{\circ}K)$ . In this case, the nodal values of the displacement are given in Table 1. The corresponding field distribution of displacement along the length of the considered rod is shown in Figure 2a). From this Table and the Figure, it can be seen that the sections of the rod that are on the site  $0 < x < 24.85\ (cm)$  move against the direction of the axis  $Ox$ . Moreover, in this direction, the section with the coordinate  $x = 13.2\ (cm)$  moves most. The value of the displacement of this section is  $u_{132} = -0.03066239\ (cm)$ . Cross-section of the rod, which are located on the site  $24.85 < x < L = 30\ (cm)$ , move in the direction of the axis  $Ox$ . In this case, a section whose coordinate is  $x = 27.4\ (cm)$  moves more than other sections. The value of the displacement of this section is  $u_{274} = 0.001973\ (cm)$ . Comparing, we find that  $|u_{132}| > |u_{274}|$ .

The nodal values of the strain components of elastic  $\varepsilon_x$ , temperature  $\varepsilon_T$  and thermoelastic  $\varepsilon$  are respectively given in Tables 2 and 3. The field distribution of these strain components along the length of the considered rod is shown in Figure 3a). From these Tables and the Figure, it can be seen that the behavior of the elastic component of the deformation in the sections  $0 < x \leq 13.15\ (cm)$  and  $27.35 \leq x < L = 30\ (cm)$  of the rod will be compressive. However, in the area  $13.15 < x < 27.35\ (cm)$  of the rod behaves tensile. The other two components of the deformation  $\varepsilon_T$

and  $\mathcal{E}$  along the entire length of the rod will have a compressive character. From Figure 3a), it is also seen that the field distribution of the components of elastic strains  $\varepsilon_x$  and thermoelastic strains  $\mathcal{E}$  will be symmetric concerning a straight line whose equation is  $\varepsilon = 0.0000033 x - 0.0052$ .

Nodal values of the component stresses of elastic  $\sigma_x$ , temperature  $\sigma_T$ , and thermoelastic  $\sigma$  are given in Tables 4 and 5. The corresponding field distribution of these component stresses is given in Figure 4a). From Tables 4 and 5, Figure 4a), it is seen that the behavior of the elastic component of the stress  $\sigma_x$  in the sections  $0 < x \leq 13.15(\text{cm})$  and  $27.35 \leq x < L = 30(\text{cm})$  of the rod will have a compressive character, and in the remaining sections of the rod  $\sigma_x$  behaves tensile. The remaining two components of stress  $\sigma_T$ , and  $\sigma$  along the entire length of the rod will have a compressive character. Also, it can be seen from Figure 4 that the distribution field  $\sigma_x$  and  $\sigma$  along the length of the considered rod will be symmetric for the straight line, the equation of which has the following form  $\sigma = 9.304x - 10326.544$  (Himushin, 1969; Myrzasheva *et al.*, 2018).

In the next step, increase the value  $T_{amb\ 0}$ , we accept  $T_{amb\ 0} = 20 (^{\circ}\text{K})$ . The corresponding displacement distribution field is shown in Figure 2b). From this graph, it can be seen that the cross-sections of the rod located on the coordinate plane section  $0 < x \leq 24.85(\text{cm})$  move against the axis direction  $Ox$ . In this direction, the greatest displacement belongs to the coordinate section  $x = 13.2(\text{cm})$ . The value is the displacement section of this section  $u_{132} = -0.0305186 (\text{cm})$ . The sections of the rod located on the site  $24.85 < x < L = 30(\text{cm})$  move in the direction of the axis  $Ox$ . In this case, the greatest displacement belongs to the point with the coordinate  $x = 27.4(\text{cm})$ , and its largest value is  $u_{274} = 0.001996 (\text{cm})$ . This also shows that  $|u_{132}| > |u_{274}|$ .

The field distribution of the elastic  $\varepsilon_x$ , temperature  $\varepsilon_T$  and thermoelastic  $\mathcal{E}$  deformation components along the length of the considered rod is shown in Figure 3b). From this figure, it is seen that the nature of the components of the deformation  $\varepsilon_T$  and  $\mathcal{E}$  along the entire length of

the rod will be compressive. In contrast, their behavior of elastic deformations  $\varepsilon_x$  in the sections  $0 < x \leq 13.15(\text{cm})$  and  $27.35 \leq x < L = 30(\text{cm})$  the rod will be compressive, and in the remaining sections of the rod  $\varepsilon_x$  behaves in a tensile manner. It can also be seen from this figure that the field distribution of the strain components along the length of the considered rod will be symmetric to the straight line  $\varepsilon = 0.0000033 x - 0.0052$ .

The field of distribution of elastic  $\sigma_x$ , temperature  $\sigma_T$ , and thermoelastic  $\sigma$  components of stress along the length of the considered rod is shown in Figure 4 b). In this case, the behavior of the components of the voltage  $\sigma_T$  and  $\sigma$  along the entire length of the rod will be compressive. In contrast, the nature of the behavior of the elastic component of the stress  $\sigma_x$  will be of a different kind. The elastic component of the stress  $\sigma_x$  is compressive in the sections of the rod  $0 < x \leq 13.15(\text{cm})$  and  $27.35 \leq x < L = 30(\text{cm})$ , and in the remaining sections of the rod  $\sigma_x$  behaves in a tensile character. Figure 4b) also shows that this field, the distribution of the voltage components  $\sigma_x$ , and  $\sigma$  along the length of the considered rod will be symmetrical to the straight line, the equation of which has the following form  $\sigma = 9.1128x - 10337.835$ .

Now consider the case when  $T_{amb\ 0} = 30 (^{\circ}\text{K})$ . The corresponding displacement field along the length of the considered rod is given in Figure 2c). From this graph, the displacement field shows that the sections of the rod located on the coordinate plane plot  $0 < x < 24.75(\text{cm})$  move against the direction of the axis  $Ox$ , the largest displacement in this direction belongs to the point with the coordinate  $x = 13.2(\text{cm})$ . The displacement value of this section is  $u_{132} = -0.03037379 (\text{cm})$ . The sections of the rod located on the site  $24.75 < x < L = 30(\text{cm})$  move in the direction of the axis  $Ox$ , the largest movement in this direction belongs to a point with a coordinate  $x = 27.4(\text{cm})$ , whose value is  $u_{274} = 0.0020191194 (\text{cm})$ . It should also be noted that  $|u_{132}| > |u_{274}|$ .

The corresponding field distribution of the elastic  $\varepsilon_x$ , temperature  $\varepsilon_T$ , and thermoelastic  $\mathcal{E}$  deformation components along the length of the

considered rod is shown in Figure 3 c). From these materials, it can be seen that the behavior of the elastic component of deformation  $\varepsilon_x$  in the sections  $0 < x \leq 13.15(\text{cm})$  and  $27.35 \leq x < L = 30(\text{cm})$  the rod will have a compressive character, and in the remaining sections of the rod  $\varepsilon_x$  behaves tensile. In contrast to elastic deformations  $\varepsilon_x$ , the behavior of the remaining components of the deformation  $\varepsilon_T$  and  $\varepsilon$  along the entire length of the considered rod will have a compressive character. It can also be seen from this figure that the field distribution of the strain components along the length of the considered rod will be symmetric to the straight line  $\varepsilon = 0.0000033x - 0.0052$ .

The corresponding field of distribution of elastic, temperature  $\sigma_x$ ,  $\sigma_T$ , and thermoelastic  $\sigma$  components of stresses is given in Figure 4c). From these results, it is clear that the behavior of the two-component stresses  $\sigma_T$ , and  $\sigma$  along the entire length of the rod will be compressive. In contrast, their elastic component of stress  $\sigma_x$  in the sections  $0 < x \leq 13.15(\text{cm})$  and  $27.35 \leq x < L = 30(\text{cm})$  the rod behaves compressive, and in the rest of it, it has a tensile character. From Figure 4c), it can also be observed that the field of distribution of the component voltages  $\sigma_x$  and  $\sigma$  are symmetric to a straight line, the equation of which has the following form  $\sigma = 8.92x - 10349.218$ . When the value  $T_{amb0} = 40(^{\circ}\text{K})$  is varied, the corresponding field of the distribution of displacement, elastic, temperature, and thermoelastic components of the deformation  $\varepsilon_x$ ,  $\varepsilon_T$  and  $\varepsilon$ ,  $\sigma_x$ ,  $\sigma_T$  and  $\sigma$  stress along the length of the considered rod is given in Figures 2d), 3d), 4d) (Demidovich and Maron, 1960; Kudaykulov *et al.*, 2009).

By analyzing the studies of this problem by values  $T_{amb0} = 10(^{\circ}\text{K})$ ;  $20(^{\circ}\text{K})$ ;  $30(^{\circ}\text{K})$ ;  $40(^{\circ}\text{K})$ , we can construct the following comparative Table 6. These results show that in the case  $T(x) = 40x$  at  $(L/3) \leq x \leq (2L/3)$ , the temperature changes with the surrounding cross-sectional area of the left end of the medium, i.e.  $T_{amb0}$ , minimal effect in comparison with  $h_0$  the thermally stressed state of the investigated rod. Earlier, it was carried out a numerical study of the laws governing the influence of the heat transfer coefficient  $h_0$  on the thermally stressed state of a rod at a temperature that varies linearly, taking into account

$\alpha = \alpha(T(x))$ .  $\alpha = \alpha(T(x))$  – the law is the distribution of the coefficient of thermal expansion along the length of the rod, which expresses the full-scale dependence between the coefficient of thermal expansion and temperature. The rod is also made of heat-resistant alloy ANV-300 and pinched by two ends.

The laws of the fields of distribution of elastic displacements, component deformations, and stresses according to the values of the heat transfer coefficient  $h_0 = 7.5$ ;  $10$ ;  $15$ ;  $30$  ( $\text{watt} / (\text{cm}^2 \cdot ^{\circ}\text{K})$ ) are constructed. Based on the results of these studies, the following comparative table 7 is constructed.

#### 4. CONCLUSIONS:

It was found that with increasing value  $h_0$ , the amplitude of displacements increases against the direction of the axis  $Ox$ , and the amplitude of displacements in the direction of the axis  $Ox$  decreases. With increasing value  $h_0$ , the maximum and average values of thermoelastic stress  $\sigma$  decreases.

Thus, it was established that only by changing the value  $h_0$ , (and not  $T_{amb0}$ ), i.e., by changing the environmental properties of the surrounding cross-sectional area where heat transfer occurs, the thermally stressed state of the rod under investigation can be changed.

RESUMO

Os resultados de um estudo da ação de compostos da fórmula geral: 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2,3,4-tetrahydroquinoline. Os estimulantes de crescimento mais eficazes dos compostos das séries 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2,3,4-tetrahydroquinoline para rododendro amarelo (*Rhododendron luteum*) e rododendro Ledebur (*Rhododendron ledebourii*). As mudas de rododendro foram contadas para estudar a germinação em laboratório e plantadas em caixotes em terreno fechado, aos 21 dias após o início do experimento. Foi estabelecido que os produtos químicos sintetizados causam estímulo ao crescimento de espécies do gênero *Rhododendron* em comparação com as preparações comerciais existentes. A eficiência do uso de soluções de compostos das séries 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2,3,4-tetrahydroquinoline e suas concentrações. É divulgado um método de utilização de compostos desta série como estimulantes do crescimento, que permite aumentar a germinação de espécies do gênero *Rhododendron* de 20 para 50%, aumentar a altura de mudas de *Rhododendron luteum* de 18 para 63% e *Rhododendron ledebourii* de 33 para 183%. As dihydroquinolinas são mais eficazes para espécies do gênero *Rhododendron*. Os compostos contendo um substituinte di-hidro-6-quinolinil estimulam o crescimento dessas plantas. A especificidade da ação dos estimulantes do crescimento é observada. A conveniência de usar compostos da série quinolina para a produção de material de plantio de plantas ornamentais para paisagismo é mostrada. Sugere-se a atividade auxina de compostos da fórmula geral: 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2,3,4-tetrahydroquinoline. Supõe-se que os compostos das séries 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2, A 3,4-tetrahydroquinoline pode ter atividade de proteção ao estresse para espécies do gênero *Rhododendron*. Os materiais do artigo são de valor prático para biólogos, ecologistas e cultivadores de plantas.

**Palavras-chave:** *estimuladores de crescimento, processos de crescimento, compostos orgânicos sintetizados, plantas ornamentais.*

ABSTRACT

The results of a study of the action of compounds of the general formula: 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2,3,4-tetrahydroquinoline are presented. The most effective growth stimulants from compounds of the series 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiopyl-1,2,3,4-tetrahydroquinoline for yellow rhododendron (*Rhododendron luteum*) and Ledebur rhododendron (*Rhododendron ledebourii*) were revealed. *Rhododendron* seedlings were counted to study laboratory germination and planted in crates in closed ground on 21 days after the start of the experiment. It was established that the synthesized chemicals cause stimulation of the growth of species of the genus *Rhododendron* in comparison with existing commercial preparations. The efficiency of using solutions of compounds of the series 1-alkyl-2,2,4-trimethyl-6-

aminocarbothioyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2,3,4-tetrahydroquinoline and their concentrations. A method of using compounds of this series as growth stimulants is disclosed, which allows increasing seed germination of species of the genus *Rhododendron* from 20 to 50%, increasing the height of *Rhododendron luteum* seedlings from 18 to 63%, and *Rhododendron ledebourii* from 33 to 183 %. Dihydroquinolines are most effective for species of the genus *Rhododendron*. Compounds containing a dihydro-6-quinolinyl substituent stimulate the growth of these plants. The specificity of the action of growth stimulants is noted. The expediency of using quinoline series compounds for the production of planting material of ornamental plants for landscaping is shown. It is suggested the auxin activity of compounds of the general formula: 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2,3,4-tetrahydroquinoline. It is assumed that compounds of the series 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2,3,4-tetrahydroquinoline may have the stress-protective activity for species of the genus *Rhododendron*. The materials of the article are of practical value for biologists, ecologists, plant growers.

**Keywords:** growth stimulators, growth processes, synthesized organic compounds, ornamental plants.

## АННОТАЦИЯ

Представлены результаты исследования действия соединений общей формулы: 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2-дигидрохинолин и 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2,3,4-тетрагидрохинолин. Выявлены наиболее эффективные стимуляторы роста из соединений ряда 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2-дигидрохинолина и 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2,3,4-тетрагидрохинолина для рододендрона желтого (*Rhododendron luteum*) и рододендрона Ледебера (*Rhododendron ledebourii*). Проростки рододендрона подсчитывали для изучения лабораторной всхожести и высаживали в ящики в закрытом грунте на 21 день после начала эксперимента. Установлено, что синтезированные химические вещества вызывают стимуляцию роста видов рода *Rhododendron* по сравнению с существующими коммерческими препаратами. Эффективность использования растворов соединений ряда 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2-дигидрохинолина и 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2,3,4-тетрагидрохинолина и их концентрации. Раскрыт способ использования соединений этой серии в качестве стимуляторов роста, который позволяет увеличить всхожесть семян видов рода *Rhododendron* с 20 до 50%, увеличить высоту сеянцев *Rhododendron luteum* с 18 до 63%, а *Rhododendron ledebourii* с 33 до 183%. Таким образом, дигидрохинолины наиболее эффективны для видов рода *Rhododendron*. Соединения, содержащие дигидро-6-хинолинийный заместитель, стимулируют рост этих растений. Отмечена специфичность действия стимуляторов роста. Показана целесообразность использования соединений серии хинолинов для производства посадочного материала декоративных растений для ландшафтного дизайна. Предполагается ауксиновая активность соединений общей формулы: 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2-дигидрохинолин и 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2,3,4-тетрагидрохинолин. Предполагается, что соединения ряда 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2,3,4-тетрагидрохинолина и 1-алкил-2,2,4-триметил-6-аминокарботиоил-1,2,3,4-тетрагидрохинолин может обладать стресс-защитной активностью для видов рода *Rhododendron*. Материалы статьи представляют практическую ценность для биологов, экологов, растениеводов.

**Ключевые слова:** стимуляторы роста, ростовые процессы, синтезированные органические соединения, декоративные растения

## 1. INTRODUCTION

Maintenance of seed quality is mandatory for the sale of seed as well as for assuring the required plant population and final yields to end-user (Sudhakar *et al.*, 2016). It is possible to increase seed germination and the quality of plants obtained from them using growth regulators (Bashmakov *et al.*, 2012). Seed lots are evaluated based on their germination capabilities and vigor (Sudhakar *et al.*, 2016). In the physiological sense, germination begins with seed water uptake and

ends with the initiation of elongation by the embryonic axis, usually the radicle (Welbaum *et al.*, 1998). However, many tests used to evaluate seed physiological characteristics require time and skilled laboratory, making it a costly process (Neverova, 2004; Vetchinnikova, 2004; Kalaev *et al.*, 2006; Takahashi *et al.*, 2006, 2007; Bukharina, 2011; Gar'kova *et al.*, 2011; Popov *et al.*, 2011; Yakymchuk, 2015; Lapshina *et al.*, 2016; Sudhakar *et al.*, 2016; Baranova, Kalaev, 2017). Models have been developed to predict germination based on thermal time, hydrotime,

and combined hydrothermal time (Welbaum *et al.*, 1998). These population-based models indicate that the timing of germination is closely tied to physiologically determined temperature and water potential thresholds for radicle emergence, which vary among individual seeds in a population (Welbaum *et al.*, 1998). The tests of the germination capability and the height of the seedlings are used in modern research (Fedorova, Shunelko, 2003; Vetchinnikova, 2004; Ivanov, 2011; Lyanguzova, 2011; Moiseeva *et al.*, 2012a,b; Bome *et al.*, 2015; Opalko, Opalko, 2015; Kuzemko, 2016; Fachi *et al.*, 2019).

Currently, an active search is underway for regulators of growth processes among new synthesized organic substances that could have a stronger positive effect compared to existing commercial preparations. Hydroquinoline derivatives with wide biological activity are essential heterocyclic compounds for the synthesis of organic and medical chemistry (Mohammed *et al.*, 1992; Shmyreva, 2000; Abadi, Brun, 2003; Saudi *et al.*, 2003; Abdel-Gawad *et al.*, 2005; Shujiang *et al.*, 2005; Williamson, Ward 2005; Denmark, Venkatraman, 2006; Trivedi *et al.*, 2008; Litvinov, 2009; Mosalam *et al.*, 2011a,b; Azizian *et al.*, 2014; Shikhaliev *et al.*, 2014; Ghoneim, Assy, 2015). It seems relevant to reveal the species-specific reactions of seedlings of herbaceous and woody plants to seed pretreatment with synthesized organic compounds, the effect of aftereffect of seed treatment, and the influence of the substitute base compound.

The purpose of the study was to study the effects of the synthesized organic compounds of the series 1-alkyl-2,2,4-trimethyl-6-amino carbothiyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiyl-1,2,3,4-tetrahydroquinoline at growth indicators (by which we meant seed germination and plant height) of *Rhododendron ledebourii* and *Rhododendron luteum*.

## 2. MATERIALS AND METHODS

Seeds were treated with compounds synthesized at the Department of Organic Chemistry of the Voronezh State University according to the methods developed by the staff, which are described in the literature (Manahelohe *et al.*, 2015a,b). Below is a general scheme for the synthesis of organic compounds of the series 1-

alkyl-2,2,4-trimethyl-6-aminocarbothiyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothiyl-1,2,3,4-tetrahydroquinoline (Fig. 1).

A mixture of the corresponding hydroquinoline carboxaldehyde (1 mmol), amine (1.33 mmol), and elemental sulfur (1.33 mmol) in dimethylformamide (2 ml) was heated under reflux until the completion of the reaction (the control by the thin layer chromatography). After cooling, the reaction mass was poured into 5 ml of ice water with vigorous stirring. The solidified after grinding, and the precipitate was filtered, washed with water, and recrystallized from 75% ethanol. Non-hardening thiocarboxamides were treated with a double excess of hot 2M hydrochloric acid, filtered and recrystallized from ethanol.

1,2,2,4-tetramethyl-6-(1-piperidinylcarbothiyl)-1,2-dihydroquinoline hydrochloride (compound 1);

1,2,2,4-tetramethyl-6-(1-piperidinylcarbothiyl)-1,2,3,4-tetrahydroquinoline hydrochloride (compound 2);

1-benzyl-2,2,4-trimethyl-6-(4-morpholinylcarbothiyl)-1,2,3,4-tetrahydroquinoline (compound 3);

1,2,2,4-tetramethyl-6-[(4-methyl-1-piperazinyl)carbothioyl]-1,2,3,4-tetrahydroquinoline hydrochloride (compound 4);

4-[(1,2,2,4-tetramethyl-1,2-dihydro-6-quinolyl)carbothioyl]-1-piperazinylcarbaldehyde hydrochloride (compound 5).

To identify the biological effects of the synthesized organic compounds, morphometric parameters of perennial woody plants: Ledebour rhododendron (*Rhododendron ledebourii* Pojark.) and yellow rhododendron (*Rhododendron luteum* Sweet.) (Alexandrova, 2003; Baranova *et al.*, 2018; Burmenko *et al.*, 2018a,b).

The seeds of the test plants were kept in aqueous solutions of the above chemical compounds at concentrations of 0.01%, 0.05% and 0.1% for 18 hours. As a traditional stimulator, the commercial preparation Epin-Extra (Russian produced by NNPP NEST M) in a working concentration according to the instructions for use - 0.05%. The control seeds were soaked in tap water. The experiment was carried out in triplicate (100 seeds in each). Seeds were germinated under laboratory conditions at a constant temperature of 22 ° C. The germination of seeds and the determination of the germination was carried out according to GOST 13056.6-97. The laboratory germination of seeds was determined as the ratio of the number of germinated seeds to the total number of seeds and was expressed in%, according to the recommendations (GOST 13056.6-97). *Rhododendron* seedlings were counted to study laboratory germination and planted in crates in closed ground on 21 days after the start of the experiment. The height of the seedlings was measured using a ruler.

Computer statistical processing was performed using the Stadia software package. The procedures for grouping data and their processing were described in the work of A. P. Kulaichev (2006). The seed germination in the control and experimental variants was compared according to the criterion of frequency agreement using Z-statistics. The comparison of mean values was carried out using Student's t-test. The influence of the chemical treatment factor at different concentrations on growth rates was determined using a two-way analysis of variance.

### 3. RESULTS AND DISCUSSION:

The results of the influence of tested chemical compounds on the germination of *Rhododendron* seeds are presented in Table 1-2.

The seed germination of Ledebour rhododendron (*Rhododendron ledebourii*) and yellow rhododendron (*Rhododendron luteum*) increase all tested chemical compounds at the concentration of 0.1%. For *Rh. ledebourii* compound 1 is the most effective and for *Rh. luteum* also compound 5 at concentrations 0.01%, 0.05% and 0.1%. A positive effect (stimulation) is observed when treating the seeds of the *Rhododendron* species with compounds 1, 3-5 in all tested concentrations (0.01%, 0.05%, and 0.1%). The germination of Ledebur rhododendron seeds under the influence of synthesized organic substances at the indicated concentrations (0.01%, 0.05%, and 0.1%) was increased from 24.3 to 54% for yellow rhododendron - from 21.4 to 56.2%.

The height of the seedlings of species of the genus *Rhododendron* grown from seeds treated by synthesized chemical compounds is presented in Tables 3-4. Compounds 1 and 5 at concentrations of 0.01%, 0.05%, and 0.1% is shown the most significant stimulating effect. All tested substances are effective at concentrations of 0.05% and 0.1%. The height of Ledebur rhododendron seedlings under the influence of synthesized organic compounds was risen from 33.3 to 183.3%, for yellow rhododendron - from 18.2 to 63.6%.

The influence of the "chemical compound treatment" and "concentration" factors was evaluated by the results of the analysis of variance, which showed a significant effect on the height of seedlings *Rh. ledebourii* ( $P < 0.05$ ), *Rh. luteum* ( $P < 0.05$ ).

Mild and moderate stress activates the body's defenses. The use of various growth stimulants that can protect the plant and reduce the harmful effects of heavy metals on the body is based on this mechanism. For example, the effect of the synthetic growth regulator of the cytokinin type of action (cytodef) and heavy metal ions:  $\text{Pb}^{2+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Zn}^{2+}$  and  $\text{Ni}^{2+}$  on the rate of generation of superoxide anion radical, the intensity of lipid peroxidation and the content of carotenoids in the leaves of 7-day-old cucumber plants (*Cucumis sativus* L., cultivar Graceful) was studied. The use of a synthetic growth regulator of the cytokinin type of action (cytodef) in some cases reduced the toxicity of heavy metals ( $\text{Pb}^{2+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Zn}^{2+}$ , and  $\text{Ni}^{2+}$ ), which was manifested in partial or complete removal of the negative effect of metals on oxidative processes and an increase in the concentration of antioxidants (carotenoids) (Bashmakov *et al.*, 2012). The use of some biological growth regulators allows one to obtain a crop with a lower content of lead and cadmium ions (Titov *et al.*, 2011).

The results of this work are consistent with earlier studies by R. G. Gafurov and co-workers on carbon N- and O-benzyl-containing compounds that have a bright auxin activity (Gafurov, Makhmutova, 2003, 2005). In this regard, it is assumed that compounds of the series 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2,3 may have the stress-protective activity for species of the genus *Rhododendron*.

#### 4. CONCLUSIONS:

Thus, the greatest effect on increasing the germination of seeds of species of the genus *Rhododendron* was produced by the synthesized organic compounds of the 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2,3,4-tetrahydroquinoline at a concentration of 0.1%. Dihydroquinolines or compounds containing a dihydro-6-quinoliny substituent are most effective. All of the compounds under consideration show a clear tendency to increase seed germination with increasing concentration. All tested substances exhibit a stimulating effect at the studied concentrations and increase the height of seedlings of species of the genus *Rhododendron* in comparison with the control. Synthesized chemical compounds of the series 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-1,2-dihydroquinoline and 1-alkyl-2,2,4-trimethyl-6-aminocarbothioyl-

1,2,3,4-tetrahydroquinoline cause the growth increase of species of the genus *Rhododendron* compared to existing commercial preparations, such as Epin-Extra, and it is advisable to use them as growth stimulators for the production of planting material.

#### 5. ACKNOWLEDGMENTS:

The study received financial support from the Ministry of Science and Higher Education of the Russian Federation within the framework of State Contract with universities regarding scientific research in 2020–2022, project No. FZGU-2020-0044

**RESUMO**

As batatas como cultura alimentar são de grande importância no mundo. As infecções virais estão entre as principais razões por trás das más propriedades das sementes do material de plantio, baixa qualidade e baixo rendimento da colheita da batata. O uso de sementes sem vírus é uma das formas com alto potencial para aumentar os índices de rendimento e a eficiência do cultivo de batata. A aeropônia é uma área promissora para o cultivo de batatas sem vírus. O estudo teve como objetivo avaliar o potencial e melhorar a tecnologia do cultivo de tubérculos de batata sem doenças usando plantação aeropônica. A tecnologia aeropônica da produção de semente de batata é uma maneira segura e econômica de produzir mini tubérculos. As práticas aeropônicas exigem menos água e energia por unidade de volume de material de sementes em comparação com as práticas convencionais de cultivo. A tecnologia elimina doenças transmitidas pelo solo e danos causados por pragas. Condições artificiais, como iluminação adicional, podem ser facilmente fornecidas em estufa para o cultivo de variedades cultivadas em diferentes regiões. Cálculos econômicos mostraram que a tecnologia aeropônica pode ser praticável na produção de sementes de batata em larga escala.

**Palavras-chave:** *planta aeropônica; mini tubérculos; batatas; material de sementes; produção de sementes.*

**ABSTRACT**

Throughout the world, potatoes, as a food crop, are very important. One of the main reasons for the poor quality of planting material, yield and potatoes themselves are viral infections. The use of virus-free seed material is one of the high-potential ways to increase the yield and efficiency of potato production. Aeroponics is a promising direction in obtaining a virus-protected crop. This study aimed to assess the potential and improve the technology for growing healthy mini-tubers of potatoes using the aeroponic method, which is a safe and economical method. Compared to the usual method of growing crops, aeroponics assumes lower water and energy costs per unit of production, as well as excludes soil diseases of the plant and does not allow damage to the tuber caused by pests. For growing different varieties of crops in different regions, artificial conditions such as additional lighting in greenhouses can be easily provided. In this study, economic calculations have shown that, from a practical point of view, Aeroponics technology may be appropriate for large-scale production of seed potatoes.

**Keywords:** *aeroponic plant; mini-tubers; potatoes; seed material; seed production.*

**АННОТАЦИЯ**

Во всем мире картофель, как продовольственная культура, имеет очень большое значение. Одной из основных причин низкого качества посадочного материала, урожайности и самого картофеля являются

вирусные инфекции. Использование безвирусного семенного материала является одним из высокопотенциальных путей для повышения урожая и эффективности картофелеводства. Аэропоника – это перспективное направление в получении защищенного от вирусов урожая. Данное исследование имело за цель оценить потенциал и усовершенствовать технологию выращивания здоровых мини-клубней картофеля с использованием аэропонного метода, являющегося безопасным и экономичным способом. По сравнению с обычной методикой выращивания сельскохозяйственных культур, аэропоника предполагает более низкие затраты воды и энергии на единицу продукции, а также исключает почвенные заболевания растения и не допускает повреждений клубня, вызванных насекомыми-вредителями. Для выращивания разных сортов сельскохозяйственных культур в различных регионах, такие искусственные условия, как дополнительное освещение в теплицах, могут быть легко обеспечены. В рамках данного исследования, экономические расчеты показали, что, с практической точки зрения, технология аэрооники может быть целесообразной при крупномасштабном производстве семенного картофеля.

**Ключевые слова:** аэропонная установка; миниклубни; картофель; семенной материал; семеноводство.

## 1. INTRODUCTION:

Potato (*Solanum tuberosum*) ranks third in the world among the most important food crops after rice and wheat; 374 million tons of potato tubers are produced in the world. However, potato yields are significantly below the yield potential in most developing countries, mainly due to poor potato seed properties (Tessema and Dagne, 2018). Due to biological characteristics, potatoes are more susceptible to viral and viroid diseases than other crops (Anisimov *et al.*, 2014). Viral diseases are among the major causes of poor potato seed properties and low productivity (Priegnitz *et al.*, 2019). As a result of multi-year reproduction, potatoes tend to accumulate diseases, mainly viral ones. The viral infections, in turn, lead to degeneration in potatoes (Li *et al.*, 2018; Dupuis *et al.*, 2019). The potato aphids and Colorado beetles transmit viruses from diseased to healthy plants, then viruses spread from one generation to another through vegetative reproduction of potatoes (Tessema and Dagne, 2018). Potato yields and storage capacity tend to decrease with each subsequent planting. Global potato losses from viral infections are 90 million tons, and the yield is reduced by 40-50%; tuber losses during storage can reach 15-20% (Adikini *et al.*, 2016; Khelifa, 2019). Such factors as the pathogen type and strain, stability rate of the variety, growing and weather conditions determine potato yield losses. Mild viral diseases reduce the yield by an average of 10-20%; potato yields drop by 70-85% in severe viral diseases. Starch values fall by 0.8-4.6% in diseased tubers compared to healthy tubers. The diseased potato tubers have lower values of crude protein, vitamin C, B<sub>1</sub>, B<sub>2</sub> (Ateş *et al.*, 2019; Inglis *et al.*, 2019; Ogero *et al.*, 2019).

Therefore, the use of the virus-free seed material is one of the high-potential ways for

increasing yield indices and efficiency of potato growing (Anisimov *et al.*, 2014; Mbiri *et al.*, 2015; Wang *et al.*, 2017; Tessema and Dagne, 2018). There are many methods for improving potato seed material (thermotherapy, chemotherapy). Thermotherapy is the treatment of plants, shoots, and tubers with high temperatures (+37 - +42 °C) for pathogen inactivation. Chemotherapy relies on the introduction of Virazole at 20-50 mg/l concentration into the nutrient medium, where apical meristems are grown. The main objective of reproducing the virus-free source material was to achieve the maximum net reproduction with the lowest risk of repeated viral infection and to produce material suitable for planting in the open ground (Anisimov *et al.*, 2009; 2014). Currently, to solve the problem, researchers use new techniques such as clonal propagation of meristem cultures and year-round reproduction of the source material in the closed environment (Lakhari *et al.*, 2018; Singh *et al.*, 2019). These are the main methods of seed material reproduction used in potato seed tuber production: improving seed material through tissue cultures and selecting the most virus-free lines; clonal propagation of micro-plants in the laboratory environment; growing disease-free mini-tubers on the protected ground or in hydroponic modules; selection of healthy source plants and clones in the field based on visual assessment and laboratory testing methods for viral, viroid and bacterial infection (Martirosyan, 2014; Oves *et al.*, 2014 Khutinaev *et al.*, 2016).

Aeroponics is a promising area for growing virus-free potatoes (Mateus-Rodríguez *et al.*, 2012; Sumarni *et al.*, 2013; Rykaczewska, 2016; Abdul *et al.*, 2018; Hajiaghahi Kamrani *et al.*, 2019;). Aeroponics is a type of hydroponics: plants are grown suspended with their roots periodically sprayed with a nutrient-rich solution. The basic principle of the aeroponic plant growing

is atomizing the plant with a mineral-rich nutrient water solution in the closed or semi-closed environment (Martirosyan, 2014; Rykaczewska, 2016b; Wang *et al.*, 2017).

Aeroponics provides opportunities for the selection of seed tubers without interrupting the vegetative growth of potatoes. The sufficient root zone provided full visual monitoring and easy access to the plant root system, careful management of the roots during multiple harvests of mini-tubers. Therefore, the number of seed tubers harvested from one potato plant was several times larger, which increased the net reproduction of high-value potato seed tubers (Mateus-Rodriguez *et al.*, 2013; Basiev *et al.*, 2019; Rykaczewska, 2016b). On average, 805 - 900 mini-tubers could be picked from the area of 1 m<sup>2</sup> (Abdullateef *et al.*, 2012; Rykaczewska, 2016b). Aeroponics allows researchers to develop fully automatic plant growing systems much more straightforward than substrate cultivation systems (Gabitov *et al.*, 2018; 2018b).

So far, this technique is not widespread and has not been adequately studied, especially in Russia. Several countries have recommended aeroponic cultivation as the most effective and convenient practice for growing plants than soil and other soilless techniques. Aeroponics based cultivation of potato seed tubers requires less water and energy (Tessema and Dagne, 2018). Aeroponics is recommended as a modern plant cultivation technique for potato seed production by the International Potato Center (CIP) (Mateus-Rodriguez *et al.*, 2013).

Although the approaches to the issue are generally the same, there is no standard practice on applying aeroponics for growing potato mini-tubers (Oraby *et al.*, 2015; Khaksar *et al.*, 2018; Zhuravleva *et al.*, 2018; Kaur *et al.*, 2019;). In this regard, the study aimed to assess the potential and improve the technology of growing disease-free potato seed tubers using an aeroponic plant.

## 2. MATERIALS AND METHODS:

The study was conducted in the laboratory of potato breeding and seed production at Bashkir State Agrarian University.

The source tubers were taken from visually healthy potato plants without frank disease symptoms. Potato tubers were placed in the thermal chamber, where the temperature was raised daily by 2°C from 25°C to 37°C during the first week. The potato tubers were kept in the thermal chamber for 14 weeks at a relative

humidity of 90%. For reducing the saprophytic microorganism population, the explants were washed with soap solution, rinsed with tap water then with reagent water type IV, and then treated with 70% ethanol solution. 0.1% diacid solution was used as a sterilizing solution. After sterilization, the explants were washed with distilled water.

The explants were appropriately tested for viral, viroid, bacterial diseases. So the material could be used for future grafting during the year, thereby reducing the costs of buying new disease-free material. The study used the Polymerase chain reaction (PCR) to diagnose viral diseases. This method offers high sensitivity as it has the advantage of producing results within 24 hours for some infections.

The cultivated plants were then grown in a nutrient medium (Figure 1).

The modified MS nutrient medium contained mineral salts and growth stimulants. PVP (polyvinylpyrrolidone) (5000-10000 mg/l) was used as an anti-oxidant. The nutrient medium was sterilized in an autoclave at 120 °C and 1 atm for 20 min. Micro-plants were grown at 3 thousand lx (16-hour photoperiod) at 25 °C and 70% of relative humidity. Then the potato micro-plants were placed in the aeroponic plant.

The study used the FTA 60 aeroponic phytotron for growing potato mini-tubers of the Alekseevsky variety (Khamaletdinov *et al.*, 2018). The FTA-60 aeroponic phytotron comprises a tray equipped with an aeroponic system (3); a rack (3); a pump station (1); a hydraulic storage unit (1); a solenoid valve (1); a container for spray solution (1); a digital timer (1); a submerged type pump (1). The phytotron can accommodate 60 plants. The plants were placed on a lightproof cover of the container with a built-in siphon tube, which was periodically one-quarter filled with the nutrient solution. The stem and leaves were above the cover and received lighting while the roots were under the cover. 1/5 of the roots were submerged in the solution, and the rest were suspended in the air between the solution and the cover. The hanging roots were recurrently sprayed with the nutrient solution through the atomizers fixed to the cover.

The study used the LED 101 W lamp under the 4:3 red and blue ratio for vegetative growth and 109 W lamp under the 3:1 ratio for tuber formation.

CFX96 Real-Time PCR Detection System was employed in the Polymerase chain reaction (PCR) method to diagnose potato virus infection.

### 3. RESULTS AND DISCUSSION:

The production of disease-free seed potato tubers consisted of three major stages: microcloning and growing of test-tube plants, cultivation of mini-tubers in the aeroponic phytotron, and planting potato tubers in the greenhouse.

The explant was isolated and introduced into the culture at the first stage. Under sterile conditions, the apical meristem, a culture of actively dividing cells, was isolated from the tip growth region and put in a nutrient medium. Apical meristems of 200-400 microns were isolated by applying micro-cuts to the plants in LAMSYSTEMS laminar flow cabinet under aseptic conditions using a 20x binocular magnifier.

The test tube plants were small (the length was 10 cm, the weight was 3-5 g), so the first three days of cultivation were crucial (Figure 2).

The study showed that the plants needed special care (watering and lighting) in that period. The root zone was kept moistened by periodic spraying of the nutrient solution. For spraying, the study used a high-pressure pump and atomizers. The plant was fixed with a soft clip or in lattice pots at the top of the container. Plants grown in the aeroponics system have a more robust root system than plants grown in the soil medium. The aeration of the roots resulted in quick absorption of nutrients. Thorough spraying of the nutrient solution is crucial in the process. It is necessary to cover all the roots with the solution droplets. The optimal droplet size for a large number of plants was 20-100 microns. This range allows small droplets to saturate the air, maintaining the required humidity level, and large droplets to fall on the plant roots and be absorbed. The solution was sprayed in the following order: at first, the nutrient solution was sprayed for 60 seconds every 15 minutes during the two weeks after planting, and then for 30 seconds every 15 minutes. This scheme eliminated drying out of the root system as the plant absorbed nutrients continuously, and reduced operating costs by saving electricity during the pump idle time.

Lighting and temperature regulation, as well as the composition of the nutrient solution, are essential in the aeroponic cultivation practice. At the initial stage (days 1-10), the lighting period was 24 hours. From day 11, the lighting period was reduced to 18 hours per day. By day 15, the plants gained vegetative weight and had a developed root system of light color. The length of

lighting was gradually reduced by 1 hour per day from day 16 to day 24. By the end of the period, the length of lighting was 10 hours per day. When the lower leaves dried (days 77-80), the light phase was reduced to 6-8 hours per day to stimulate tuber growth; this increased necrosis of the top and stimulated outflow of plastic substances from the top into the tubers.

The optimal temperature for the first three potato growth stages was 22-24/16-18°C day/night (Adikini *et al.*, 2016). The second half of the growing season (stages 4,5) requires decreasing temperature to 18-20°C during the day and to 14-16 °C at night (Adikini *et al.*, 2016). The temperature requirements were met in the study.

'Basaplant' soluble fertilizers served as a basis for the nutrient solution. 'Basaplant 15-10-15 +ME' and 'Basaplant 8-12-24 +ME' soluble fertilizers were used in 0.7:0.3 ratio during the first period of the plant growing. The solution-specific conductance was 0.8-0.9 millisiemens (mSm), the acidity (pH) was 7.7-6.9 from day 1 to day 16. The acidity level gradually decreased to 6.3 by day 14 and 5.7 by day 16. The optimal acidity level (pH 6,9-6,7) was maintained by adding the tap water with a high level of calcium salts and sodium bicarbonate. However, the yellowing of the lower leaves was observed in some plants on day 13; the number of plants with yellowed leaves increased on day 15. Therefore, the concentration of the nutrient solution was increased from day 17 to day 20, and the specific conductance was 1.1 mSm.

Ferrous sulfate was added to the nutrient solution to eliminate iron-induced chlorosis. However, the resultant solution appeared ineffective. Therefore, on day 20, the solution was enriched with NPP compounds such as ammonium nitrate, potassium sulfate, and double superphosphate as well as micro-fertilizers such as hydrogen borate and potassium permanganate. The specific conductance raised to 1.8 mSm, and the level was maintained to day 31.

'Basaplant 8-12-24 +ME' soluble fertilizer was applied from day 32 to day 51. The fertilizer contains little nitrogen (8%), phosphorus (12%), and much potassium (24%). The specific conductance reached 1.8-1.9 mSm, so the solution concentration was decreased by adding water until the specific conductance fell to 1.3-1.4 mSm.

'Basaplant 15-5-30' fertilizer was applied at the next stage (from day 54 to harvesting). The specific conductance was maintained at 1.3-1.4

mSm from day 54 to day 62. Then, the concentration of the nutrient solution was gradually decreased from day 63 to day 74, so the specific conductance fell to 1.1 mSm, from day 75 to day 79 the index fell to 1.0-0.9 mSm. The solution-specific conductance was kept constant (0.7-0.9 mSm) till the end of potato harvesting.

The study demonstrated that concentration indices should be monitored daily and be kept at the optimum level via adding fertilizers or water; the solution acidity should be managed by changing the nutrient solution or adding calcium carbonate or phosphoric acid. The optimum acidity for potato growing should be maintained at 6.8-7.4. The nutrient solution should be replaced at least twice a month.

Harvesting of potato mini-tubers started on day 96. The harvesting was over on day 108.

Thirty-four mini-tubers were picked from one potato plant (Figure 3). The maximum weight of a tuber was 78 g. The yield of the optimum sized tubers (20-30 mm in diameter) was 72.1 percent. Large tubers (more than 30 mm) were 9.3 %, small tubers (15-20 mm) were 11.4%, and smaller tubers (< 15 mm) were 7.2 %.

The yield of the optimum sized mini-tubers was 969 pcs from 1 m<sup>2</sup> of the FTA-60 aeroponic plant. The study analysed the costs for aeroponic production of seed potato mini-tubers, and the analysis showed that the cost of one seed potato minituber was 10 roubles.

Production of seed potato mini-tubers allows it to grow potato mini-tubers free from viral infections. The aeroponics technology optimizes access to air and carbon dioxide for potato growth as opposed to practices involving a substrate medium. The yield of the optimum sized mini-tubers was 969 pcs from 1 m<sup>2</sup> of the FTA-60 aeroponic plant. This figure is slightly higher than indices obtained by some growers *in regular medium* (805-900 mini-tubers per 1 m<sup>2</sup>) (Abdullateef *et al.*, 2012; Mateus-Rodriguez *et al.*, 2013).

Aeroponic production of potato mini-tubers requires systematic monitoring for temperature, humidity, light intensity, nutrients, pH, and mSm indices of the nutrient solution, spraying length, and time. The study used controls to adjust the parameters. Wireless sensors introduced into the aeroponic technology can ensure early detection of the parameter fluctuations. So, the farmer could monitor several parameters without using laboratory instruments (Lakhia *et al.*, 2018).

The optimal temperature for the first three

potato growth stages was 22-24/16-18°C day/night. The second half of the growing season (stages 4,5) requires decreasing temperature to 18-20°C during the day and to 14-16°C at night (Adikini *et al.*, 2016). The temperature parameters are consistent with the findings obtained by other researchers (Oraby *et al.*, 2015). The density of planting in the aeroponic unit is crucial for successful plant growth. In the study, tubers were planted at a density of 40 plants per 1m<sup>2</sup>. The plant density of 60 plants per m<sup>2</sup> showed the most significant results (Abdullateef *et al.*, 2012).

Several researchers have proved that aeroponics-based technology is effective in potato seed production (Mateus-Rodriguez *et al.*, 2013; Martirosyan, 2014; Rykaczewska, 2016b; Tessema and Dagne, 2018). At the same time, some growers point out (Chang *et al.*, 2012; Tican *et al.*, 2017) that the hydroponics technology is also a successful strategy for the production of seed potatoes. The hydroponic system employs a circulating nutrient solution; it has a positive effect on the average weight of mini-tubers per plant. Moreover, aeroponics technology requires a constant power supply and trained maintenance personnel throughout the crop growing season. Unreliable power supply and expensive boiler-based sterilization methods for growing media hinder the successful application of aeroponics technology. Mini-tubers produced in the sand culture hydroponic system were larger than grown based on the conventional aeroponics technology. The initial cost of the hydroponic unit and the cost of the sand hydroponics system per season is lower than that of the conventional aeroponics system. Sand hydroponics can replace the traditional system of quality seed potato production (Mbiri *et al.*, 2015) and general potato growing techniques in crop growing (Rodríguez-Delfín, 2011).

#### 4. CONCLUSIONS:

The aeroponic practice of seed potato production is a safe and economical way to produce mini-tubers. Less water and energy per volume unit of seed material are needed for aeroponic systems compared to the hydroponic growing practice. The aeroponic technology optimizes access to air and carbon dioxide for potato growth as opposed to practices involving a substrate medium. Aeroponics can prevent disease transmission as the diseased plant can be quickly removed. The technology eliminates soil-borne diseases and pest damage. Artificial conditions such as additional lighting can be easily

provided in the greenhouse for cultivating crop varieties grown in different regions.

**RESUMO**

A avicultura ocupa um lugar especial garantindo a demanda do consumidor pelos produtos da indústria, que fornece à população produtos alimentares essenciais, tais como ovos e carne, que contêm micro e macro nutrientes vitais, proteínas, lipídios e vitaminas. Portanto, as questões da alimentação racional e economicamente viável de aves de galinheiro, como galinhas de corte, são tarefas urgentes. Também é essencial encontrar métodos eficazes de aplicação para corrigir a resistência natural e a reatividade imunológica e biológica das aves. O objetivo desta pesquisa é estudar o efeito do estimulante biológico Nucleostim no crescimento e desenvolvimento de galinhas, parâmetros hematológicos e imunológicos do sangue de aves. Na aplicação de Nucleostim, o ganho de peso vivo de frangos aumentou 9,7%. No final do experimento, a habitabilidade dos pintos do grupo experimental tratado com Nucleostim chegou a 88%, comparado com os 72% do grupo de controle. O uso de Nucleostim teve um efeito estimulante no fígado de galinhas, contribuindo para o desenvolvimento do timo no contexto da distrofia geral. Assim, Nucleostim melhora a habitabilidade dos pintinhos e aumenta o ganho de peso corporal. O estimulante biológico Nucleostim como agente adaptógeno, anabólico e imunoestimulador é promissor para encontrar novos medicamentos que melhorem a saúde e a produtividade das aves.

**ABSTRACT**

Poultry farming holds a special place in ensuring the products that the consumers demand, it provides the population with essential food products, such as eggs and meat, that contain vital micro and macronutrients, proteins, lipids, and vitamins. Therefore, the issues of rational, economically feasible feeding of meat poultry, namely broiler chickens, are an urgent task. It is also essential to find effective methods of their application in order to correct the natural resistance and immune and biological reactivity of birds. The purpose of this research is to study the effect of the biological stimulant-Nucleostim on the growth and development of chickens, hematological, and immunological parameters of the blood of birds. This Biostimulant is a purified bovine spleen extract containing at least 1 mg / ml of low molecular weight peptides (nucleotides and nucleosides) formed as a result of autolysis, using dry whey and diatomite as fillers. On the application of Nucleostim, the gain in live weight of chickens was increased by 9.7%. At the end of the experiment, the livability of the chicks of the experimental group treated with Nucleostim came up to 88%, compared with the 72% of the control group. The use of biostimulant had a stimulating effect on the liver of chickens confirmed by the research results presented in the article, as well as contributed to the development of the thymus in the setting of general dystrophy. Thus, it improved chick livability and increased body weight gain. The biological stimulant-Nucleostim as an adaptogenic, anabolic, and immunostimulatory agent is promising for finding new drugs that improve the health and productivity of poultry.

**Keywords:** Chickens, growth and development, livability, Nucleostim, poultry farming, resistance.

## АННОТАЦИЯ

Птицеводство занимает особое место, так как обеспечивает население необходимыми пищевыми продуктами, такими как яйца и мясо, которые содержат жизненно важные микро- и макроэлементы, белки, липиды и витамины. Поэтому вопросы рационального, экономически целесообразного кормления мяса птицы, а именно цыплят-бройлеров, являются актуальной задачей. Также важно найти эффективные методы их применения для коррекции естественной резистентности и иммунной и биологической реактивности птиц. Целью данного исследования является изучение влияния биологического стимулятора-Нуклеостима на рост и развитие цыплят, гематологические и иммунологические показатели крови птиц. Этот биостимулятор представляет собой очищенный экстракт бычьей селезенки, содержащий не менее 1 мг/мл. низкомолекулярных пептидов (нуклеотидов и нуклеозидов), образованных в результате автолиза, с использованием сухой сыворотки и диатомита в качестве наполнителей. При применении Нуклеостима прирост живой массы цыплят увеличился на 9,7%. В конце эксперимента выживаемость цыплят экспериментальной группы, получавших Нуклеостим, достигла 88% по сравнению с 72% контрольной группы. Применение биостимулятора оказало стимулирующее действие на печень кур, подтвержденное результатами исследований, представленными в статье, а также способствовало развитию вилочковой железы в условиях общей дистрофии. Таким образом, это улучшило жизнеспособность цыплят и увеличило прирост массы тела. Биологический стимулятор Нуклеостим как адаптогенное, анаболическое и иммуностимулирующее средство является перспективным для поиска новых лекарств, улучшающих здоровье и продуктивность домашней птицы.

**Ключевые слова:** цыплята, рост и развитие, живность, нуклеостим, птицеводство, устойчивость.

## 1. INTRODUCTION:

Poultry farming provides the population with essential food products – eggs and meat that contain easily digestible proteins, lipids, trace elements, and vitamins. Therefore, the issues of rational, economically feasible feeding of poultry, namely broilers, appear relevant. Preliminary results of 2019 indicate that the volume of poultry meat production in Russia has grown by 1.3%: from 4.98 million tons in 2018 to 5.045 million tons. Poultry meat farming surpasses all other livestock industries in terms of feed conversion. The production of 1 kg of broiler meat requires 1.5 and 2.5 times less feed than the same amount of pork and beef. In the world ranking of poultry producing countries, Russia is among the top five countries. The main factors of production growth are the implementation of innovative processes and comprehensive modernization of poultry farming within the framework of the national project “Development of agriculture” and the State program for agricultural development (Government of the Russian Federation, 2012; Buyarov and Buyanov, 2015; Fisnin *et al.*, 2017; Buyarov *et al.*, 2018).

World meat production is constantly increasing. In 2016, it was 259.3 million tons, and in 2019 it raised to 301 million tons. The production of meat of all animal species in the world increased sevenfold between 1950 and 2019. The maximum

growth rate for the same period is in line with the production of poultry meat – 11.8-fold. In 2018, in the structure of world production, pork accounted for 37.4% of meat in the slaughter-weight; poultry – for 34.1%; beef – for 22.2% and lamb – for 4.5%. According to the FAO forecast for 2011-2025, the annual increase in meat will be 3.1% for poultry, 2.6% for pork, and 1.3% for beef. The most significant amounts of poultry meat consumption are observed in the UAE, Israel, Hong Kong, the United States, Singapore, and Brazil (Gharahveysi *et al.*, 2020).

Estimates show that following the results of 2019, poultry meat production in the world will come up to 106 million tons. Of these, 20.111 million tons are produced in the United States; 18.517 – in China; 11.500 million tons – in Brazil. The E.U. indicator will reach 12.738 million tons, with an increase of 188 thousand tons over the year. By 2020, Brazil will be among the largest exporters of poultry meat, taking the leading position, followed by the United States, China, the European Union, and Russia.

The viability of broiler chickens is an essential factor in determining the profitability of poultry farming. Chicken embryo tissues contain a high proportion of polyunsaturated fatty acids in the lipid fraction and therefore need antioxidant protection. The antioxidant system of the developing embryo and newly hatched chicken includes antioxidant enzymes, water-soluble

antioxidants, fat-soluble antioxidants, and selenium. Natural antioxidants play a pivotal role in the maternal diet affecting the development of chicken embryos and their viability in their early neonatal life (Gharahveysi *et al.*, 2020).

Upon zootechnical and economic indicators, floor-grown broilers of the cross Ross-308 were more effective than broilers of the cross Hubbard f 15. The profitability of production and sales of meat from Ross-308 cross broilers was higher than that of Hubbard f 15 cross broilers by 1.9% (Buyarov *et al.*, 2018).

The level of metabolic energy in poultry feed is one of the most critical indicators that ensure optimal growth and development of the body (Fisinin, 2013). Various feed additives, fats, and oils are used to optimize the composition of feed for broilers in terms of this indicator. They have the highest caloric content among all types of feedstock, and therefore constitute the main source of energy for poultry (Fisinin *et al.*, 2017). When choosing a food source for feeding broilers, in some cases, it is necessary to take into account not only the level of live weight gain, feed conversion, and carcass quality but also the indicators that characterize the quality of the meat itself.

Boosting the production of eggs and poultry meat is based on a significant increase in the productivity of birds with a simultaneous increase of the poultry stock with a high payment for feed by meat products and a rise in labor productivity (Nozdrin *et al.*, 2018).

However, at present, great importance is attached not only to increase the number of poultry, but also, mainly, to increase their viability, the resistance of the organism, productivity, improving meat qualities, and egg production (Fisinin *et al.*, 2017). The latter depends on the genetic-environmental interaction.

The use of biological stimulants is one of the most promising areas in poultry farming (Dementyev *et al.*, 2018).

Several authors cite data on studies of the nature of autarcesis of birds on increasing live weight and egg production, preserving poultry stock, viability, and its variability as affected by the external and internal environment. Despite this, many aspects of the presented problem remain unexplored, such as improving the quality of meat, reducing the time of poultry rearing, increasing the degree of mineralization of the organic matrix of bone tissue and bone density in the process of growth and development (Buyarov *et al.*, 2012,

2018; Fisinin, 2013; Ahmadiet *al.*, 2018; Jahanian and Ashnagar, 2018; Nozdrin *et al.*, 2018; Rubio *et al.*, 2019).

Despite the available information on the use of biological stimulants, this issue remains relevant. It is also important to find effective methods of their application in order to correct the natural resistance and immune and biological reactivity of birds.

Poultry farming plays a significant role in providing the population with high-quality food. Interest in this industry is constant both in large specialized enterprises and on small farms. At the same time, the species range of captive birds, from ostriches to quails, is expanding, although industrial production of meat and eggs of chickens is more traditional for agriculture (Buyarov *et al.*, 2018). Also, to achieve that technological capacities have been established, conditions for keeping and feeding poultry have been brought about. Low feed consumption, a short period of reproduction, the plasticity of an organism of hens and chicks are the advantages of breeding poultry (Fisinin, 2013).

However, the genetic potential of the birds' organism for meat production is not enough. One of the keys to an extensive increase in poultry production capacity is to find opportunities for the use of biologically-active preparations, i.e., medicinal substances with bioactive properties and a regulating effect on the growth and development of birds, the intensity of exchange processes; enhancing the functional activity of organs and body systems; increasing autarcesis of the organism of birds and at the same time safe for own body and its products to humans and the environment (Julean *et al.*, 2013).

In connection with the above, the research objective was to study the effect of the biological stimulant biostimulator on the growth and development of chickens, hematological, and immunological parameters of the blood of birds.

Biostimulant is a purified bovine spleen extract containing at least 1 mg/ml of low molecular weight peptides (nucleotides and nucleosides) formed as a result of autolysis, using dry whey and diatomite as fillers.

## 2. MATERIAL AND METHODS:

One hundred broiler chickens of the crosses ROSS 308 and Rodonit were used for the research. The conditions for conducting

experiments were identical for the control and experimental groups, and they meet the requirements of "Sanitary rules for the construction, equipment, and maintenance of experimental and biological clinics (vivariums)" No. 1045-73 as well as of GOST (All-Union State Standard) R 53434-2009 "Principles of good practice" corresponding to international GLP standards. The diet of the young birds consisted of a balanced complete feed PC-2 produced by the Bogdanovich feed mill (Table 1). Water was supplied *ad libitum*.

Biopreparation was used in the study – a water-soluble premix for poultry containing natural growth stimulants represented by low molecular weight biologically active peptides–nucleosides and nucleotides. Bioadditive was introduced into the diet of birds in the right concentrations and fed with the feeding stuff according to the instructions for use – broiler chickens: 10 g/kg of feed every other day for ten days. The optimal dose of biopreparation was 10 g/kg of feed. The investigational product mixed with feed was given daily for ten days.

The live weight was determined by individual weighing using laboratory electronic scales AND GF-600. The broiler stock was weighed from the first to the ninth week of research (Figure 1). The chick livability was determined by taking into account the mortality rate.

The development of internal organs was determined by necropsy from the 30<sup>th</sup> to 38<sup>th</sup> days of chickens' life at the Department of morphology, pathology, pharmacy, and non-infectious diseases of Bashkir state agrarian university (Russia) with further evaluation of the weight and size of internal organs.

Anatomical and morphological methods were used to measure the size, weight, and topography of internal organs (Skovorodinet *al.*, 2019). The central organs of the bird's immune system (thymus, spleen, Bursa), heart, and liver were used as research materials. The investigational organs were weighed by analytical laboratory scales AND GF-600.

Based on the data obtained, the relative weight of the organ was calculated.

Modern clinical assessment of general condition, thermometry, assessment of mucous membranes, pulse rate and breathing, assessment of feather cover, hematological (erythrocytes, hemoglobin, color index, leucocytes) and biochemical research

methods (total protein, protein fractions, total bilirubin, AST, ALT) were used in the work.

Hematological studies of whole blood were performed using an automatic hematological analyzer Abacus Junior 5Vet (Diatron Messtechnik GmbH), which determines 22 hematological parameters: leucocytes,  $10^9/l$ , lymphocytes, %, lymphocytes,  $10^9/l$ , monocytes %, monocytes,  $10^9/l$ , neutrophils, %, neutrophils,  $10^9/l$ , eosinophils %, eosinophils,  $10^9/l$ , basophils, %, basophils,  $10^9/l$ , erythrocytes,  $10^{12}/l$ , hemoglobin, g/l, hematocrit, %, mean corpuscular volume, fl, mean contents of hb in er., pg, mean hb conc. in er, g/l, the distribution range of erythrocytes population, %, platelets,  $10^9/l$ , platelet count, %, average platelet volume, fl, distribution range of platelets population, %).

Verification and calibration of the hematological analyzer were carried out within the framework of in-laboratory control with the formulation of studies of standardized whole blood samples with normative and pathological values of indicators issued by Diatron Messtechnik GmbH. Biochemical blood tests were performed using a semi-automatic biochemical blood analyzer StatFax 1904+ (Awareness Technology Inc.,) using standardized reagents Vital Diagnostics Spb.

### Statistical analyses

The obtained data were statistically processed using Microsoft Excel.

### Ethical issues

The experiments are approved by the Commission on Bioethics of Bashkir state agrarian University established to monitor and evaluate the policy of working with laboratory animals, methodological and experimental base for the humane treatment of animals and their rational use, guided by the legislation of the Russian Federation, the provisions of the "European Convention for the protection of vertebrates used for experimental and other scientific purposes", as well as the provisions of the Guide for the Care and Use of Laboratory animals and other rules of international law which regulate the maintenance and use of laboratory (experimental) animals (Protocol No. 18-2020 of January 14, 2020).

## 3. RESULTS AND DISCUSSION:

The immunobiology of the animal organism during fetal development is characterized by certain features. First of all, during this period of ontogenesis, germinal organs are formed and function – the placenta, gall bladder, allantois, and amnion, which perform metabolic and fetus-protecting functions. Protection of the fetus by temporary germinal organs involves maintaining the immunological balance of the mother and the fetus and preventing infection of the latter. The chicken organism is also able to transmit its own antibodies transovarially. Poor supply of the fetus with maternal antibodies in itself implies the autoreproduction of antimicrobial factors by the fetus. The antimicrobial activity of autarcesis plays an important role in the life of chickens.

As known, many biological stimulants have an anabolic effect due to the increased formation of nucleic acids and protein in the liver and muscles. Therefore, the live weight of broiler chickens was one of the main indicators in the study of the properties of biopreparation. The values of the live weight of birds when compared with the norm and control, the average daily gain, as well as the livability of the broiler stock for the entire time of the experiment, were paid attention to (Julean *et al.*, 2013).

The experiment conducted involved adding the biological product Nucleostimat a dose of 10 g/kg of feed into the diet of broiler chickens of the cross ROSS-308 in order to stimulate growth as well as protect them from diseases during rearing.

Day-old chickens were divided into 2 groups. The first group totaling 50 birds was fed standard feed with the addition of vitamins, trace elements, and biopreparation at a dose of 10 g/kg. The second group consisting of 50 chickens, was fed standard feed and served as the control.

It is known that in the postnatal period, the growth of chickens depends on the initial weight of biologically active tissue. The live weight of the cross ROSS 308 chickens was  $40.5 \pm 0.4$  g in the experimental group and  $39.9 \pm 0.3$  g in the control group.

Chickens are markedly affected by an indoor microclimate. Constant temperature (in the first days up to 32°C), light regime, humidity, and air exchange were maintained in the poultry house (Dementyev *et al.*, 2018).

The development of chickens is affected by compound poultry feed (crumb) with the correct calorie-protein ratio and their enrichment with vitamins, trace elements, and antibiotics, which

increases the biological usefulness of the feed (Salem *et al.*, 2018).

It is known that getting weighty chickens in the first week of fattening can affect the degree of increase in body weight in the following weeks (Table 2).

The table shows that during the first week of life, the increase in live weight of chickens fed biopreparation increased by 9.7% compared with the control. After three weeks, chickens treated with bioadditive overweighed the control by 87.4 g, and in 5 weeks, the average live weight of broiler chickens exposed to biopreparation was  $1060.0 \pm 15.0$  g and of control chickens –  $848.5 \pm 15.0$  g. The chickens of the experimental group overweighed the control ones by 211.5 g.

At the end of the study, that is, at the age of 9 weeks, the average live body weight of one chick fed biostimulator was  $2180.0 \pm 50.0$  g, and of the control –  $1850.5 \pm 48.5$  g.

Thus, the chickens exposed to bioadditive overweighed the chickens of the control group by 290.5 g.

At the end of the experiment, the livability of the experimental group of chickens was 88%, and of the control group – 72%.

As a result of the use of bioadditive at a dose of 10 g/kg of feed, there has been an overall survival growth of chickens and an increase in the live weight gain.

The second set of experiments was performed for therapeutic purposes with 36 64-day-old chickens of the cross Rodonit which were rejected due to general dystrophy (failure in growth, weight, development) and divided into three following groups of 12 birds each:

1. Control
2. bioadditive at a dose of 10 g/kg of feed
3. bioadditive at a dose of 5 g/kg of feed.

The chickens were weighed at the age of 64, 74, 84, and 94 days. The data obtained are shown in Table 3.

Analyzing the obtained data, it can be observed that the chickens of the experimental group had a significantly high average daily increase compared to the chickens of the control group. The highest results were observed in the group of chickens fed biopreparation at a dose of 10 g/kg of feed. So, throughout the research, the increase in live weight of chickens in that group was 104.4%, in the group of chickens exposed to biological stimulator at a dose of 5 g/kg of feed –

93.3% compared to chickens in the control group.

The chick livability in the experimental and control groups was similar. In the control group, nine chickens lived through the experiment, and the mortality rate was 20%; in the second group, 11 chickens survived, or 91.6%, and in the third group – 90%.

The impact of bioadditive on the development of internal organs was studied on 30-38 days old chickens. Four groups of 10 birds each were formed. The test stock was fed standard mixed feed. In addition, to feed, the biostimulant under investigation was given daily for ten days. Group 1 – biological stimulator (10 g/kg of feed). Group 2 – biological stimulator (5 g/kg of feed). Group 3 – biological stimulator (15 g/kg of feed). Group 4 – control.

The effect of the biopreparation was evaluated by the condition of the digestive organs (liver, glandular stomach) and the immune system (thymus, Bursa). Special attention was paid to the central immune organs of birds since they all grow rapidly in the first months of life and reach maximum development: the thymus by 3.5-4 months, and the Bursa by 4-4.5 months. Then thymus gradually mummifies upon reaching puberty.

Autopsies were performed from the 30<sup>th</sup> to 38<sup>th</sup> day of the life of chickens at the Department of morphology, pathology, pharmacy, and non-infectious diseases of Bashkir state agrarian university. No pathological changes were found in the organs. The weight and size of internal organs were evaluated. The study data are shown in Table 4.

Table 4 shows that in three experimental groups, the weight of the internal organs of broiler chickens is greater than in the control group. The most significant increase in organs was observed in chickens exposed to bioadditive at a dose of 10 g/kg of feed.

When conducting research for therapeutic purposes on 64-day-old cross Rodonit chickens with clinical signs of general dystrophy, deficiency in live weight, and failure in growth and development were found. According to domestic and foreign sources, there is a correlation between the condition of some internal organs and the overall condition of the body of chickens. So, when the depletion increases, the thymus lobes grow less, and when the feed ration of birds improves, the gland regeneration begins in parallel (Skovorodin *et al.*, 2013).

Studies have shown that throughout the

experiment, the development of the thymus was registered in all groups of chickens. Apparently, this was due to improved feeding during the study period.

The absolute weight of the thymus in the control group of chickens was  $0.8 \pm 0.07$  g, and in chickens fed biopreparation at a dose of 10 g/kg of feed –  $1.006 \pm 0.03$  g which was 0.206 g more.

Thus, the use of biostimulator contributed to the development of the thymus in chickens in the setting of general dystrophy.

The absolute weight of the liver of Rodonit cross chickens that were treated with biopreparation at doses of 10, and 5 g/kg of feed at the age of 64-days was  $12.25 \pm 0.35$  and  $10.85 \pm 0.18$  g, respectively, which was 2.05 and 0.65 g more than the liver weight of the control chickens.

In such a way, bioadditive has a stimulating effect on the liver of chicks of experimental and control groups. At the same time, the relative weight of the organ is less than in control, which implies physiological hepatomegaly.

The blood system is directly involved in specific and non-specific reactions of the body affecting its resistance and reactivity. Blood readily responds to any exposure and serves as an important criterion for the physiological condition of the animal body and the metabolic rate.

The study of morphological and immunological parameters of chicken blood was carried out by many researchers. However, there are splits over the dynamics of blood indicators of young chickens. It was found that they changed depending on the age and physiological state of chickens, which indicated a different intensity of metabolic processes in each period of their life, which was confirmed by our research.

The stimulatory action of various biostimulants on hematopoiesis, and especially on leukopoiesis, has been mentioned by many scientists.

Morphological studies have shown that the use of biostimulator did not have any significant impact on the dynamics of indicators of red and white blood of birds. During the experiment, they were within the physiologically normal state for that age and type of production.

The minimum content of red blood cells and hemoglobin was registered at the age of 30 days (Table 5), which was consistent with the data of domestic and foreign scientists. By the 40<sup>th</sup> day of the life of chickens (in the first set of

experiments), the indicators increased on average by 14.8%. After the treatment with biopreparation, the content of red blood cells in the second experimental group (Nucleostim 10 g/kg of feed) increased by 16% compared to the control.

At the age of 40 days, the difference in the content of red blood cells in the experimental and control groups raised up to 10.5-31.6% and of hemoglobin – to 10.8-24.6% (Table 5).

In the blood of experimental and control groups of chickens, the content of white blood cells was found to be quite high, which was typical for that age. The leukogram of the chickens of experimental and control group showed the ratio of individual white blood cells within the physiological range, but some specific features were observed. For example, the percentage of eosinophils and basophils in the control group was 20% higher than in the experimental group, which indicated a more pronounced sensitization of chickens in that group (by 30 days of age, the chickens were challenged with five different vaccines). At the same time, a slight increase in the number of lymphocytes (by 3-8%) in the blood of chickens of the experimental groups compared to the control indicates the mobilization of the immune system in response to exposure, including the use of the compounds under investigation (Table 6).

An increase in the level of lymphocytes in the blood indicates an enhancement in the specific immunity of birds since these cells are the main executive element in the manifestation of cellular and humoral protection of the body.

It is known that many biological stimulants can increase the phagocytic activity of white blood cells. This increases both the number of phagocytic cells and the number of microbes they absorb (Tang *et al.*, 2007).

To characterize the system of non-specific immunity in birds when exposed to the investigational product bioadditive the functional activity of pseudo-eosinophils, monocytes and platelets of the whole blood of chicks in phagocytic reactions (for phagocytic number and phagocytic index) and the reduction reaction of nitro blue tetrazolium (spontaneous and latex-induced NBT-test) and the level of complement in blood serum have been studied.

The results of the research are shown in Table 7, analyzing which one can see that before the experiment, the phagocytosis indicators and the level of complement in the blood of chickens were within the physiological range. When re-analyzing the blood of animals after the use of the

compounds under investigation, there were significant deviations in the indicators of the experimental groups compared to the control (Table 7).

In groups using biostimulator, there was an increase in the absorption activity of white blood cells, and in the level of complement compared to the control group. The complementary activity of the blood serum of chickens in those groups increased by 24.6 and 25.6% compared to the control group. The average number of latex particles absorbed by a single cell (PHI) was 23% higher than in the control group. The activity index of pseudo-eosinophils in the "spontaneous" test increased by 50% compared to the control, and by 6.7% when induced by latex, respectively. The optimal effect was observed at a dose of 10 g/kg of feed. Reducing the dose to 5 g/kg of feed led to a slight decrease in the functional activity of phagocytes.

Thus, the use of bioadditive had a stimulating effect on the phagocytic activity of pseudo-eosinophils, monocytes, and platelets of the blood of birds and on the complement system – a non-specific factor of humoral immunity. The new biological stimulant Nucleostim is recommended for use in veterinary medicine as an adaptogenic, anabolic, and immunostimulating agent and is promising for finding new drugs that improve the health and productivity of poultry.

Many biological stimulants have an anabolic effect due to the increased formation of nucleic acids and protein in the liver and muscles. Therefore, the live weight of broiler chickens was one of the main indicators in the study of the properties of biopreparation. Attention was drawn to the values of the live weight of birds when compared with the norm and control, the average daily gains as well as the livability of the broiler stock throughout the experiment (Julean *et al.*, 2013; Khaziev *et al.*, 2018; Santos *et al.*, 2019).

The development of chickens is affected by compound poultry feed (crumb) with the correct calorie-protein ratio, their enrichment with vitamins, trace elements, and antibiotics, which increases the biological usefulness of the feed (Sharipova and Khaziev, 2015; Salem *et al.*, 2018).

It is known that getting weighty chickens in the first week of fattening can affect the degree of increase in body weight in subsequent weeks (Buyarov *et al.*, 2018). In the first week of life, the live weight gain of chickens treated with bioadditive increased by 9.7% compared with the control chickens. After three weeks, the chickens exposed to biostimulator overweighed the control

ones by 87.4 g, and after five weeks – by 211.5 g.

At the end of the study, that is, at the age of 9 weeks, the average live body weight of one chick treated with biostimulator was  $2180.0 \pm 50.0$  g and of the control –  $1850.5 \pm 48.5$  g. The chickens exposed to biostimulator outweighed the control chicks by 290.5 g. At the end of the experiment, the livability of the experimental group of chickens was 88%, and of the control group – 72%.

As a result of the use of bioadditive at, a dose of 10 g/kg of feed, there is an increase in the livability of chickens and an increase in their live weight gain. The livability of chickens in the experimental and control groups was similar. In the control group, nine chickens lived through the experiment, and the mortality rate was 20%; in the second group, 11 chickens stayed alive or 91.6%, and in the third group – 90%.

The effect of the biopreparation on internal organs was assessed by the state of the digestive organs (liver, glandular stomach) and the immune system (thymus, Bursa). Special attention was paid to the central organs of immunity in birds since they all grow rapidly in the first months of life and reach maximum development: the thymus by 3.5-4 months and the Bursa by 4-4.5 months. Then the thymus gradually mummifies upon reaching puberty (Nasrin *et al.*, 2012; Skovorodin *et al.*, 2013).

No pathological changes were found in the organs. The weight and size of internal organs were estimated (Tanget *et al.*, 2007; Skovorodin *et al.*, 2019).

When conducting research for therapeutic purposes on 64-day-old Rodonit cross chickens with clinical signs of general dystrophy deficiency in live weight and failure in growth and development were found. According to domestic and foreign sources, there is a correlation between the state of some internal organs and the general state of the body of chickens. Thus, when the depletion increases, the thymus lobes grow less and when the feeding diet of birds improves, the gland regeneration begins in parallel (Aluwong *et al.*, 2013; Skovorodin *et al.*, 2013; Fisinin *et al.*, 2017; Jahanian and Ashnagar, 2018; Rubio *et al.*, 2019).

Studies have shown that throughout the experiment, the development of the thymus was registered in all groups of chickens. Apparently, this was due to improved feeding during the study period. Biostimulant Nucleostim has a stimulating effect on the liver of chicks of experimental and control groups. At the same time, the relative

weight of the organ is less than in control, which indicates physiological hepatomegaly.

The study of morphological and immunological parameters of the blood of broiler chickens was carried out by many researchers. However, there are splits over the dynamics of blood indicators of young chickens. It was found that they changed depending on the age and physiological state of chickens, which pointed to a different intensity of metabolic processes in each period of their life, which was confirmed by our research. The stimulating effect of various biostimulants on hematopoiesis, and especially leukopoiesis, has been noted by many scientists (Julean *et al.*, 2013; Sharipova and Khaziev, 2015; Salem *et al.*, 2018; Khaziev *et al.*, 2020).

Morphological studies have shown that the use of biopreparation did not have a significant impact on the dynamics of indicators of red and white blood of birds. During the experiment, they were within the physiological range for that age and type of productivity. The minimum content of red blood cells and hemoglobin was registered at the age of 30 days, which was consistent with the data of domestic and foreign scientists. After application of biopreparation, the content of red blood cells in the second experimental group (biostimulator 10 g/kg of feed) increased by 16% compared to the control group (Buyarov *et al.*, 2012; Fisinin, 2013; Ahmadi *et al.*, 2018; Buyarov *et al.*, 2018; Jahanian and Ashnagar, 2018; Nozdrin *et al.*, 2018; Rubio *et al.*, 2019).

In the blood of experimental and control groups of chickens, the content of white blood cells was found to be quite high, which was typical for that age. The leukogram of experimental and control groups of chickens showed the ratio of individual white blood cells to fall within the physiological range, but some specific features were observed. An increase in the level of lymphocytes in the blood indicates an increase in the specific immunity of birds since these cells are the main executive element in the manifestation of cellular and humoral protection of the body (Buzala *et al.*, 2017).

Many biological stimulants can increase the phagocytic activity of white blood cells. This increases both the number of phagocytic cells and the number of microbes absorbed by them (Buyarov *et al.*, 2012, 2018; Fisinin, 2013; Ahmadi *et al.*, 2018; Jahanian and Ashnagar, 2018; Nozdrin *et al.*, 2018; Rubio *et al.*, 2019).

To characterize the system of non-specific immunity in birds when exposed to the investigational product Nucleostim, the functional

activity of pseudo-eosinophils, monocytes, and platelets of whole blood of chicks in phagocytic reactions (for phagocyte number and phagocytic index) and the reduction reaction of nitro blue tetrazolium (spontaneous and latex-induced NBT-test) and the level of complement in blood serum were studied (Cuetos *et al.*, 2017; Abdulameer, 2018).

Thus, the use of biopreparation had a stimulating effect on the phagocytic activity of pseudo-eosinophils, monocytes, and platelets of birds' blood and on the complement system – a non-specific factor of humoral immunity. The new biological stimulant Nucleostim is recommended for use in veterinary medicine as an adaptogenic, anabolic, and immunostimulatory agent and is promising for finding new drugs that improve the health and productivity of poultry.

The new biological stimulant is recommended for use in veterinary medicine as an adaptogenic, anabolic, and immunostimulating agent and is promising for finding new drugs that improve the health and productivity of poultry

#### 4. CONCLUSION:

The body weight gain of chickens exposed to bioadditive increases by 9.7%; after three weeks, chickens treated with biopreparation overweighed the control group by 87.4 g, after five weeks – by 211.5 g. The livability of the experimental group of chickens was 88%, and of the control group – 72%. As a result of the use of biopreparation at a dose of 10 g/kg of feed, there is an increase in chick livability and an increase in their live weight gain.

The use of the biostimulant contributed to the development of the thymus in chickens against the background of general dystrophy. It had a stimulating effect on the liver of chicks of the experimental and control groups. At the same time, the relative weight of the organ is less than in control, which indicates physiological hepatomegaly. The use of biostimulator had a stimulating effect on the phagocytic activity of pseudo-eosinophils, monocytes, and platelets in the blood of birds and on the complement system – a non-specific factor of humoral immunity.

**RESUMO**

A relevância do estudo se deve à prevalência e aumento da incidência de endometriose, principalmente em pacientes jovens, sua influência na função reprodutiva e a falta de diagnóstico não invasivo confiável da doença e seus estágios. Não existem opiniões unificadas sobre a etiologia e patogênese multifatorial desta doença. Este artigo tem como objetivo revelar os mecanismos de formação de estágios de endometriose com base no estudo do efeito da produção de citocinas, metabólitos de óxido nítrico e metabolismo lipídico. A principal abordagem para estudar esse problema é investigar os níveis sistêmico (soro sanguíneo) e local (líquido peritoneal), sua comparação. Isso permite uma consideração abrangente da patogênese da doença e a determinação do valor dos fatores biologicamente ativos mencionados, dependendo dos estágios da doença. O artigo apresenta novos dados sobre o conteúdo de lipoproteínas de alta e baixa densidade, colesterol, fator de crescimento transformador  $\beta 1$  e fator de necrose tumoral  $\alpha$ , conteúdo de metabólitos de óxido nítrico e sua interpretação clínica é dada de acordo com os estágios da doença. Os materiais do artigo são de valor prático para pesquisadores de endometriose e praticantes de ginecologistas e obstetras.

**Palavras-chave:** *endometriose genital externa, lipoproteínas, óxido nítrico, fator de crescimento transformador beta 1, fator de necrose tumoral alfa.*

**ABSTRACT**

The relevance of the study is due to the prevalence and increase in the incidence of endometriosis, especially in young patients, its influence on reproductive function, and the lack of reliable non-invasive diagnosis of the disease and its stages. There are no unified views on the etiology and multifactorial pathogenesis of this disease. This article is aimed at revealing the mechanisms of the formation of endometriosis stages basing on the study of the effect of cytokines production, nitric oxide metabolites and lipid metabolism. The main approach to study this problem is both to investigate systemic (blood serum) and local (peritoneal fluid) levels, their comparison. This allows comprehensive consideration of the pathogenesis of the disease and determination of the value of the mentioned biologically active factors depending on the stages of the disease. The article presents new data on the content of high- and low-density lipoproteins, cholesterol, transforming growth factor  $\beta 1$  and tumor necrosis factor  $\alpha$ , the content of nitric oxide metabolites

and their clinical interpretation is given according to the stages of the disease. The materials of the article are of practical value for researchers of endometriosis and practicing obstetrician-gynecologists..

**Keywords:** *external genital endometriosis, lipoproteins, nitric oxide, transforming growth factor beta 1, tumor necrosis factor alpha.*

## АННОТАЦИЯ

Актуальность исследования обусловлена распространенностью и ростом заболеваемости эндометриозом, особенно у пациенток молодого возраста, влиянием его на репродуктивную функцию, отсутствием надежной неинвазивной диагностики заболевания и его стадий. Нет единых взглядов на этиологию и многофакторный патогенез этого заболевания. В связи с этим, данная статья направлена на раскрытие механизмов формирования стадий эндометриоза на основании изучения влияния продукции цитокинов, метаболитов оксида азота и обмена липидов. Ведущим подходом к исследованию данной проблемы является исследование как системного (сыворотка крови), так и местного (перитонеальная жидкость) уровней, их сопоставление. Это позволяет комплексно рассмотреть патогенез заболевания и определить значение обозначенных биологически активных факторов в зависимости от стадий заболевания. В статье представлены новые данные по содержанию липопротеинов высокой и низкой плотности, холестерину, трансформирующего фактора роста  $\beta 1$  и фактора некроза опухолей  $\alpha$ , содержанию метаболитов оксида азота и дана их клиническая интерпретация в соответствии со стадиями заболевания. Материалы статьи представляют практическую ценность для исследователей эндометриоза и практикующих врачей акушеров-гинекологов.

**Ключевые слова:** *наружный генитальный эндометриоз, липопротеины, оксид азота, трансформирующий фактор роста бета 1, фактор некроза опухоли альфа.*

## 1. INTRODUCTION

Endometriosis is a chronic, recurring, genetically determined, inflammatory disease. Its main clinical manifestations are persistent pain and infertility. According to morphological and functional properties It is a benign growth outside the uterine cavity tissue similar to the endometrium (Adamyan *et al.*, 2016).

About 2-10% of women of the reproductive age in the population suffer from this disease (Adamyan *et al.*, 2016; Falcone and Lebovic, 2011) and up to 50% of women screened for infertility (Vercellini *et al.*, 2011). Still there are no non-invasive markers of external genital endometriosis (EGE). Scientists discuss the problem of the systematic progression of this disease but no solution is found.

Processes occurring in the peritoneal cavity play an important role in the development of external genital endometriosis in patients of the reproductive age. The amount of peritoneal fluid (PF) is known to be increased in women with endometriosis comparing with healthy women without endometriosis (Sonova *et al.*, 2010). PF in these patients is characterized by a high content of activated macrophages (Berbic *et al.*, 2009) producing cytokines: TNF- $\alpha$  (Sonova *et al.*, 2011), TGF- $\beta 1$  (Ermolova, 2009) stimulating angiogenesis (Wang *et al.*, 2009) and also

contains a large amount of lipoproteins, especially of low density, which generate oxidized lipid components as part of a macrophage inflammatory medium (Anderson Sanches Melo *et al.*, 2010)

The TGF- $\beta 1$ , found in high concentrations in the PF of patients with EGE (Charles *et al.*, 2010), has anti-inflammatory properties and is able to inhibit TNF- $\alpha$ , IL-1 $\beta$  and other cytokines synthesis, inhibit endothelial cell proliferation.

Information on the TNF- $\alpha$  role in the cell is rather contradictory, and often it produces opposite effects on the same cell types (Laschke, 2011). TNF- $\alpha$  activates lipolysis and inhibits lipogenesis.

The development of so-called local aseptic inflammation and immunocompetent cell dysfunction is generally considered as a fact established both in an experimental model of endometriosis in mice and in the abdominal cavity of patients with endometriosis (Schmidt *et al.*, 2015). In endometriosis macrophages are not able to perform their all functions, and an estrogen-dependent chronic inflammation is triggered (Takebayashi *et al.*, 2014). Imbalance in the formation of free radicals makes the basis of the inflammatory process in endometriosis (Darling, 2013).

Nitric oxide plays the role of a universal regulator of many biological functions having both protective and damaging character. Thus, being an important regulator of vascular tone, providing immune responses, neuronal transmission and antioxidant protection, nitric oxide can under certain conditions also act as a free radical, which has a pronounced destructive effect (Babushkina, 2009; . Bryan *et al.*, 2009). Nitric oxide is formed in cells from L-arginine under the action of NO-synthase enzyme (Vanin, 2008). There is a second way of converting L-arginine, by means of arginase, it is hydrolyzed to ornithine and urea, followed by the formation of proline (Babushkina, 2009), which in turn is a source of tissue hardening, and, it is well known, moderate and severe degree of EGE in 100% of cases is accompanied by the development of the adhesive process (Luciano and Adhesion, 2008). In this case, the problem is not only in the clinical manifestations of the adhesive process (pelvic pain, infertility) (Chernukha, 2011), but also in the high recurrence rate after mechanical adhesiolysis during laparoscopy. Arginase and NO-synthase compete with each other for a common substrate - L-arginine. Arginase, an enzyme in the urea synthesis cycle, has a higher activity and exceeds that of NO-synthase (Vanin, 2008).

N. Santanam *et al.* (2002), found the presence of an acidic environment in the PF of women with endometriosis. PF lipoproteins in patients with endometriosis have a greater ability to oxidation compared with blood plasma lipoproteins.

Many scientists search for new non-invasive markers of endometriosis, and biochemical and immunohistochemical indicators already developed are unfortunately not specific (Vodolazkaia, 2012; Gajbhiye *et al.*, 2012). Additional studies are necessary to determine the effectiveness of the early diagnosis of dyslipidemia in order to prevent endometriosis in patients of reproductive age. Of particular interest is the participation of cytokines, metabolites of nitric oxide and lipoproteins in the formation of the stages of the disease, which will allow to personalize the treatment tactics of these patients.

The purpose of the study was to determine clinical significance of lipid and cytokine markers status, nitric oxide metabolites in the formation of disease stages in patients of reproductive age with external genital endometriosis.

## 2. MATERIALS AND METHODS

The study, approved by the Local Ethics Committee of the Research Institute of Obstetrics and Pediatrics at Rostov State Medical University, included 96 patients, 74 were patients with EGE and 22 women without endometriosis (control group) who underwent examination and treatment at the gynecology department of the Research Institute of Rostov State Medical University.

All patients were divided into 3 clinical groups: group I consisted of 28 patients with I-II stages of EGE according to r-AFS classification (1985), group II - 46 patients with stages III-IV of the disease. The III control group consisted of 22 patients without endometriosis.

To achieve the above purpose, the following methods were used: clinical (medical history, examination), laboratory, ultrasound, endoscopic (laparoscopy, hysteroscopy, colposcopy), histological examination of biopsy specimens obtained during laparoscopy.

The following criteria were used to include the patients into the study: Criteria for the inclusion of patients in the study: 1. The patient underwent endoscopic surgery (laparo- and hysteroscopy), confirming EGE with subsequent morphological verification of the diagnosis, in patients without EGE to exclude tubal-peritoneal infertility factor, sterilization. 2. Reproductive age of patients. 3. Complaints of infertility and/or pain. 4. Body mass index 18.5 - 25 kg/m<sup>2</sup>.

The criteria for the exclusion from the study were the puberty and perimenopausal age of the patients, obesity or metabolic syndrome.

The patients were included into the study after obtaining informed consent and were recorded according to the standards of the Ethics Committee of the Russian Federation (protocol No. 46 dated 04/17/2014). Blood, peritoneal fluid of patients obtained by laparoscopy was used in the study.

Analysis of clinical data showed that in all patients menstrual cycle was preserved, its mean duration in group I (EGE stage I-II) was  $28.04 \pm 1.2$  days, in group II (EGE stage III-IV) -  $28.7 \pm 1.4$  days, in group III (control) -  $26.1 \pm 1.3$  days. Early menarche (up to 11 years old) was more common in patients with EGE from group II (60.9%) and group I (52.7%), i.e. in patients with EGE, early menarche was found, unlike patients in the control group. The mean age menstruation beginning was in group I  $10.2 \pm 0.11$  years, in group II -  $11.8 \pm 0.19$  years, in group III -  $13.4 \pm$

0.1 years. Algomenorrhea occurred in 50% of patients with EGE with menarche, in 85.1% of patients with I-II stage of EGE and only in 21.7% of patients with III-IV stage of EGE.

34.9% of patients with EGE complained of progressively increasing pelvic pains, before and during menstruation 54%, dyspareunia 22%, spotting blood excretions before or during menstruation 28%. It should be noted that with minimal forms of the disease, pelvic pain was found only in 4% patients, while in severe forms (stage III-IV of EGE) this symptom was present in more than half (55.2%) of patients which is significantly higher ( $p < 0.05$ ) when conducting intergroup comparisons. Psychoemotional disorders were in 38% in patients with EGE. Progression of the disease leads to increased frequency of symptoms. The severity and intensity of complaints prevailed in the group of patients with III - IV stage of EGE.

40.8% with EGE had primary infertility. In patients with EGE I-II stages it was registered in 68% of cases, which was 1.2 times higher than in the group with EGE III-IV stages, 39.5%. Secondary infertility was in 21.2% with EGE: in the first group of patients it was in 28% of patients and in the second group – in 23.6% of patients.

79.7% of the patients with stage I-II EGE (group I) had in their anamnesis sexually transmitted infections (STIs), and inflammatory diseases of the pelvic organs (PID) in 57.4% of patients, while in group II patients with EGE of the III-IV stage of STIs were found in 78.3%, and PID - in 60.9% of women.

Analysis of the duration of the disease from the onset of clinical manifestations to the 1st hospitalization revealed that this period ranged from 3 months to 6 years.

In 53.9% of patients ultrasound examination showed endometrioid cysts from 4 to 10 cm in size with a fine suspension of both unilateral (4%) and bilateral (95%). Only in 18% of patients with EGE typical endometrioid infiltrates from 2.5 to 3 cm were identified in the area of the uterine isthmus.

Colposcopy revealed background diseases of the cervix in 60.1% of patients with EGE stage I-II, in 76.6% of patients with EGE stage III-IV, while cervical dysplasia was found in 16.9% of in group I patients and in 21.7% group II patients. In the control group of patients, background cervical pathology was found in 30%, and cervical dysplasia in 10% of women.

In all cases surgical treatment was performed by laparoscopic access in the organ-saving volume. The main tasks of laparoscopic treatment were: maximum removal of all endometrioid foci; elimination of the adhesive process; restoration of the normal anatomy of the internal genital organs. Endometriosis prevalence was determined by laparoscopy using the recommendations of the revised classification developed by the American Society for Fertility (r-AFS) (1985). In our study, laparoscopy revealed a high percentage of endometrioid ovarian cysts (53.97%), which may indicate the untimely diagnosis of EGE. Superficial foci of endometriosis in the ovaries were detected in 42.8% of cases. Sacro-uterine ligaments (77.7%) and the rectum-uterine space (69.8%) lesions were most common, while in the vesicoureteral space foci of endometriosis were detected only in 31.7% of cases. On the wide uterus ligament endometriotic lesions were detected less often - 4.7% of cases.

In patients of the first group with EGE stage I-II, adhesions of the I degree were found in 12.8% of patients, of the II degree – in 10.8%, of the III degree – in 2.7%, and of the IV degree – in 2%. In women of the second group, with EGE stage III - IV, adhesions were found in 12%, 16.3%, 17.4%, 16.3% of cases, respectively.

In stage I-II, ovarian lesions were registered in 31% of cases, endometrioid cysts in 4%. Only peritoneum lesion was in 66.2%, combined forms - (peritoneum and ovaries) – in 48.7%. In EGE stages III - IV ovarian lesions in the form of endometrioid cysts were revealed in 94.6% of cases. Damage to the peritoneum was in 40.2% of cases. Combined forms (peritoneum and ovaries) were in 78% of patients.

Hysteroscopy revealed endometrial hyperplastic process in the form of simple hyperplasia without atypical signs was detected in 27% of group I patients and in 35.3% of group II patients, while in the control group this pathology was found only in 5% of women.

EGE was histologically confirmed in all patients of clinical groups I and II. Endometriosis verification was carried out according the degree of the process prevalence and the morphofunctional characteristics of heterotopic foci. The morphological diagnosis was based on the microscopic detection of ectopic endometrioid epithelium in combination with elements of the endometrioid stroma. Macrophages containing hemosiderin were also found in it. Endometrioid heterotopy was microscopically presented by an

accumulation of cellular formations, tubular, branching or cystically dilated. Internally the glands were lined with a cylindrical epithelium, sometimes even with cilia. In heterotopic foci, there were two types their existence – progression and regression. Proliferation of glandular epithelium of varying severity, secretory changes, decidualization of the cytogenic stroma were most common and typical for the progressing EGE foci. Regressing OGE foci without signs of functional activity were characterized by the presence of cystic gland transformation, epithelial atrophy, fibroplastic restructuring and angiomatosis of the cytogenic stroma in 19.6% of all patients, in EGE I-II stages – in 13.5% of patients, III- IV stages - in 24.5% of women. Histological examination of the surgical material revealed endometrial glands in endometrioid heterotopia in 71.7% of cases, 49.6% of patients had it in the proliferation phase, 50.4% of patients – in the secretion phase, and 18.3% in the middle secretion phase – 18.3%, in late - 81.7%. Since laparoscopy was performed in the first phase of the menstrual cycle, the data obtained indicate that in half of cases there was no correlation of the state of endometrioid heterotopy to the uterine cycle.

Angiomatosis was more pronounced (24.5% of cases) in patients with EGE stage III-IV. Moreover, in the stroma surrounding the gland, a mild lymphoid and plasmocytic infiltration was in 11.7% of cases of a focal character. As a percentage, there were no differences in EGE stages. Thus, at stage I-II they made 13.4% and in EGE stage III-IV - 12.5%. Stromal sclerosis was found in 55.7% of EGE patients. Moreover, diffuse sclerosis, which develops at the end of inflammation, or chronic insufficiency of blood supply, was in 50% of cases, while focal sclerosis occurred in 25% of patients. In OGE stage I-II it was revealed in 43.9% of patients, in stage III-IV – in 65.2% of patients. Hyalinosis was found in 33.4% of patients, and it was more pronounced with OGE stage III-IV – 42.9% of patients, versus 21.6% of patients with stage I-II of the disease. Inflammation in the stroma of endometrioid heterotopia in was found in 34.9% of cases in the general group, in OGE stages I-II – in 43.2% of patients, in stages III-IV – in 28.3% of patients. It should be noted that inflammatory changes in endometrioid heterotopies are more pronounced in EGE stage I-II, while sclerosis and tissue hyalinosis as outcomes of this process prevail in patients with EGE stage III-IV.

Serum lipoproteins and EGE were determined using Randox kits (Germany) on

Sapphire-400 biochemistry analyzer (Japan). The endogenous level of nitric oxide in the form of a nitrite anion (NO-) was determined using Griss reagent. Nitroxide synthase (NOS) activity was assessed by the increased nitric oxide production from L-arginine in the presence of NADPH. Growth factors, cytokines, were determined by enzyme-linked immunosorbent assay using “R&D Systems” kits (USA). Statistical data processing was carried out using the Statistica licensed software package (version 5.1, made by Stat Soft). The sample size in the work completely corresponds to the range of obtaining a confidence interval of probability, 0.95, and accuracy of calculation of statistical parameters, 0.05. Results are presented as median and interquartile interval. The significance of differences between the compared parameters was determined by the Mann-Whitney criterion for nonparametric distributions. The results were considered to be statistically significant at  $p < 0.05$ . In correlation analysis of the data, the Pearson criterion was used in the case of a normal distribution of variables and otherwise the Spearman criterion, and the significance level was 0.05.

### 3. RESULTS AND DISCUSSION

The results obtained in patients with stages I-II of EGE are presented in Table 1. It shows that the content of TGF- $\beta$ 1 in the blood serum in these was 1.4 times higher compared to the control group of women ( $p < 0.004$ ).

The study of lipoproteins revealed significant changes in the content of HDL in the blood serum, characterized by their increase of 1.1 times ( $p < 0.013$ ) (Table 1). Nitric oxide (NOx) metabolites content in the blood serum of patients with I-II stages of EGE was 6.9 times higher than in the control group ( $p < 0.041$ ), while NO synthase activity was not change significantly and remained at physiological level.

At stage III-IV of EGE, the content of TNF- $\alpha$  in the blood serum of patients was 1.9 times higher compared with the data of women in the control group ( $p < 0.014$ ).

Significant changes in the content of the studied lipid fractions concerned only HDL both in minimal and severe forms of EGE ( $p < 0.013$  and  $p < 0.06$ , respectively). The content of NOx in the blood serum of patients with III-IV stages of EGE (Table 1) was 13.4 times higher than in the control group ( $p < 0.001$ ).

The study of the lipid spectrum in the PF in patients with stages I-II of EGE showed the increase of free cholesterol 1.43 times content, HDL - 1.73 times and HDL - 1.6 times ( $p < 0.008$ ,  $p < 0.004$ ,  $p < 0.003$ , respectively) (Table 2).

The content of TNF- $\alpha$  in the PF in patients with stages III-IV of EGE was 1.5 times less compared with the control group of women ( $p < 0.050$ ) (Table 2), while the level of TGF- $\beta$ 1 in these patients was 1.7 times higher than the control ( $p < 0.001$ ).

The content of NOx in the PF of patients with III-IV stages of EGE was 3.3 times higher than in patients in the control group ( $p < 0.039$ ) (Table 2). The activity of NO synthase exceeded physiological parameters by almost 1.5 times ( $p < 0.001$ ).

There is no doubt that for the most successful solution of the EGE problem it is necessary to use modern methodological approaches, in particular, a comprehensive study of the molecular basis of the disease development and the relationship of metabolic disorders at the local and systemic levels. Formation of the disease stages is of special interest since it makes the basis for the further management of patients. The proliferation factors of endometrioid heterotopia (cytokines and growth factors) and metabolic (lipid) parameters that affect the activity of enzymes involved in the processes of angiogenesis were studied.

Biologically active polypeptides - growth factors that stimulate or inhibit angiogenesis, and also regulate cellular mitogenic effects play an important role in the regulation of intracellular metabolism. This refers to TGF $\beta$ 1 (Burlev, 2012; Ermolova, 2008; Ermolova, 2009). TGF $\beta$ 1 inhibits proliferation and induces differentiation of most types of cells that have been studied already. As for TGF $\beta$ 1 metabolic features, it inhibits NO synthase activity and activates arginase (Babushkina, 2009). Significance of the systemic level of regulation of metabolic processes that control cell growth (TGF- $\beta$ 1) in the study indicates the presence of compensatory reactions in patients with I-II EGE stages.

It was shown in the experiments that incubation of recruited macrophages with cholesterol causes a significant increase in TGF- $\beta$ 1 (Schwartz, 2009). Cholesterol can directly induce the synthesis and secretion of TGF- $\beta$ 1 in monocytes - macrophages.

Variations in the lipid content of cell membranes can also significantly change the

activity of proteins that are their components (Keelet, 2012). In the presence of inflammatory processes in the body, cholesterol and phospholipids content changes. Cell membranes, mainly the middle phospholipid layer, with intensively occurring processes, serve as a screen to reflect the aggressive effects of the cascade of toxic products. As a result of the changes caused, the structure, membrane functions, balance between radical oxidative processes and the functional antioxidant defense system are disturbed. A large number of low-density lipoproteins (LDL) generate very low-density lipoproteins (VLDL) (oxidized components), which enhance the growth of heterotopia by activating endometrial cell growth factors (Verit, 2013; Melo, 2010).

HDL increase causes paraoxonase-1 (PON-1) increase in the content, which is a part of lipoprotein complex, and, consequently, its activity. Study of the paraoxonase gene polymorphism (Kolesnikova *et al.*, 2012) confirms this proposition, which showed the absence of its differences compared with the parameters in patients of the control group. HDL modification in women with EGE I-II stages at the systemic level is compensatory in nature, aimed at preventing the formation of more "significant" endometrioid heterotopia in the peritoneal cavity.

Increase in nitric oxide production is due to the activation of the nitrite reductase pathway for its synthesis. NO metabolites hyperproduction contributes to the progression of endometrioid heterotopia due to vasodilation of the existing vessels and the formation of new ones by stimulating migration and proliferation of endothelial cells (Sonova *et al.*, 2010). Nitric oxide is also known as a powerful anti-apoptotic compound, high generation of which plays an important role in the synthesis and deposition of collagen, which contributes to the formation of adhesions (Adamyan *et al.*, 2016; Guidice, 2010).

An almost 2-fold increased TNF- $\alpha$  level enhances the induction of phospholipase A2 (FLA2), which is involved in the triggering of the arachidonic acid cascade, resulting in the synthesis of prostaglandins that cause pain syndrome. According to our study, 68.9% of patients with EGE suffered periodic pains before or during menstruation, 8.1% had dyspareunia. 66.0% of patients had dysmenorrhea with menarche, which was significantly higher than in the control group (13.6%). TNF- $\alpha$  acts on proliferating cells by enhancing apoptosis. These patients had an inflammatory process, since TNF- $\alpha$  synthesis is observed in stimulated cells,

suggesting that its high level is the result of infection, which was found in 78.3% (pelvic inflammatory diseases) and in 14.4% (sexually transmitted infections) of patients.

LDL in patients with stages III-IV of the disease at the system level corresponded to control values. This is provided by an increased HDL content, which includes the enzyme paraoxonase, which protects against LDL oxidation. This enzyme promotes the breakdown and elimination of oxidized cholesterol. High levels of HDL cholesterol (hLDPV) in patients with external genital endometriosis at all stages of the disease suppresses inflammation. This situation follows from the previously identified inflammatory process in the pancreas, confirmed by the increased content of proinflammatory cytokines (TNF- $\alpha$  and IL-1 $\beta$ ) in it (Ermolova, 2008). However, it was found that in the inflammatory process, HDLPs change their function to pro-inflammatory due to a decrease in the concentration of the main HDL apolipoprotein - ApoA. It provides reverse transport of cholesterol to the liver and increases the activity of paraoxonase. If the detected high level of HDL in the pancreas increases the anticoagulant properties of red blood cells - on the one hand, and on the other hand, it manifests pro-inflammatory properties on the background of the inflammatory process, which enhances inflammation, then a complex metabolic situation is revealed when it is difficult to determine which HDL function predominates.

In the pancreas of women with I-II stages of EGE, the increased LDL level ( $p < 0.003$ ) was found comparing to the control data, which may be the result of compensatory reactions aimed at increasing the activity of PLA2, LDL structural unit.

A correlation analysis of the actual material was carried out in the experiment. Significant negative correlation between the content of free cholesterol and metabolites of nitric oxide ( $r = -0.8$ ) in the blood serum and between free cholesterol and the activity of NO synthase ( $r = -0.85$ ) is of special interest. The revealed regularity shows that at the systemic level there is a dependence of nitric oxide production and NO-synthase activity on the lipid spectrum, and in particular, on the level of free cholesterol in women with EGE I-II stages.

Changes in TNF- $\alpha$  production suggest that there is a reduced function of this cytokine as an angiogenesis factor (Guidice, 2010) and cell proliferation in the pancreas. TNF- $\alpha$  regulatory

capabilities in the pancreas are determined by its ability to induce apoptosis and produce antibacterial protective effect. In this case they are sharply reduced.

Change of metabolic processes at the systemic level can play a significant role in their disruption at the local level. First, TGF- $\beta$ 1 high level as a factor that reduces proliferation is controlled by the central cerebral structures. However, modification of the molecular relationships of lipid metabolism (HDL) with angiogenic compounds in endothelial cells increases NO generation, causing an increase in heterotopies blood supply. It should be pointed out that a high level of TGF- $\beta$ 1 inhibits NO-synthase, reducing one of the reactions of NO formation, i.e. the development of compensatory processes occurs at the systemic level.

Thus, the metabolic features of the formation of I-II stages of EGE in patients at the systemic level (blood serum) are significantly increased levels of TGF- $\beta$ 1, HDL and nitric oxide metabolites. Besides, significant changes in the content of lipid metabolism products were found in the pancreas (local level). They were characterized by a significant increase in cholesterol, HDL and LDL, which contribute to the formation of oxidative stress in the abdominal cavity.

In EGE stages III – IV a high level of TGF- $\beta$ 1 is a factor in the development of fibrosis, which underlies the adhesive process. According to the data obtained by of N.V. Ermolova (2008), a high level of this growth factor is due to the inflammatory process both at the systemic and local levels.

Nonsteroidal products of the mevalonate lipid exchange pathway perform prenylation of small G-proteins (Rho, Rac), which ensure their integration into membranes and manifestation of functional activity. Modification of molecular bonds of lipid metabolism in endothelial cells increases NO generation, causing an increase in blood supply to endometrioid formations.

In this study, in women with EGE stages III-IV, different lipid fractions were differentiated in connection with the existing metabolic relationship of the mevalonate lipid exchange pathway and the generation of the main vasodilator, nitric oxide. In EGE stages III-IV, an increase in HDL content at the systemic level obviously plays a significant role in the state of lipid metabolism at the local level.

The increased blood supply to endometrioid heterotopia is due to the high content of nitric oxide metabolites in the pancreas of patients with EGE stages III-IV stages. This compound is a powerful vascular growth factor, vasodilator, and apoptosis inhibitor (Guidice, 2010). NOx excess is accompanied by oxidative stress and acts as a mutagenic, carcinogenic, and antiapoptotic factor (Sonova *et al.*, 2010; Adamyan *et al.*, 2016). High NOx generation in the pancreas, is due to the NO-synthase pathway, as evidenced by the high activity of this enzyme. There are few reports on the increased NO-synthase expression in endometrioid heterotopies, which can be explained by the presence of a functionally defective enzyme form or the secondary nature of this process (Kinugasa, 2011; Cayci, 2011; Rogers *et al.*, 2013).

The revealed very high NO generation in the peritoneal fluid can play an important role in the development of hypoxia. Recently, it has been proved that in the case of excessive NO production, its interaction with superoxidion ( $O_2^-$ ) is observed with the formation of peroxynitrite ( $ONOO^-$ ), a powerful oxidizing agent that modifies hemoglobin and changes its affinity for oxygen (Zinchuk, 2006). The latter leads to a decrease in the oxygen-binding properties of blood, and, consequently, to hypoxia, which leads to cellular metabolism disorders during endometriosis foci formation of (Taylor *et al.* 2002; Lee *et al.*, 2009).

Correlation analysis of the studied parameters in the blood serum of patients with EGE stages III-IV showed a close positive relationship between the HDL level and TNF- $\alpha$  content of ( $r = 0.60$ ). In this case, a negative correlation between NO-synthase activity and the TGF- $\beta 1$  level ( $r = -0.33$ ) was found. A significant negative relationship was in the peritoneal fluid between HDL and NO ( $r = -0.75$ ).

There is no doubt that the accompanying inflammatory process, immunological dysregulation, apoptosis inhibition, angiogenesis activation, and oxidative stress in the abdominal cavity are pathogenetic factors contributing to the survival and growth of endometrioid heterotopies (Adamyan, 2016).

Patients from our clinical sample mainly complained of infertility and / or pain, so we tried to find an explanation of their origin within the limits of our studies. We found prevalence of primary infertility regardless of the EGE stage. However, in percentage terms, both primary and

secondary infertility prevailed in patients with EGE stage I-II stage (57.1% and 32.1%, respectively). Apparently, both ovarian factors and the adhesion process in the abdominal cavity, characterized in our conditions by the involvement of the peritoneum of the sub-ovarian fossa and cul-de-sac, which may interfere with fertilization. The decrease in the ovarian reserve was due to the existing formation of endometrioid ovarian cysts from 3 to 10 cm, marked high TGF- $\beta 1$  content, influencing arginase and, subsequently, enhancing the synthesis of proline, the main substrate of the connective tissue. On the other hand, it is not possible ignore in this connection (with TGF $\beta 1$ ) the importance of high nitric oxide generation due to nitrite reductase synthesis in the absence of NO-synthase activity changes, which also contributed to the formation of adhesions. In this metabolic situation, significantly high HDL levels both in blood serum and peritoneal fluid should be taken into consideration, since they contribute to high generation of nitric oxide metabolites and the formation of oxidative stress.

The pain syndrome in our patients was probably due to the significant production of prostaglandins, which, on the one hand, were stimulated by high TNF- $\alpha$  content, which activates phospholipase A2 (a structural unit of LDL). On the other hand, the high generation of nitric oxide metabolites, changing the metabolism of arachidonic acid, acts on cyclooxygenase and thereby stimulates the formation of prostaglandins.

The revealed changes in the relationship of the lipid spectrum, growth factors, and angiogenic compounds are the theoretical basis for additional therapeutic measures aimed at normalizing metabolic processes in OGE.

#### 4. CONCLUSION

In patients with EGE stages I-II a high content of TGF- $\beta 1$ , HDL and nitric oxide metabolites was found in the blood serum (systemic level). Modification of metabolic processes at the systemic level plays a significant role in disrupting them locally (peritoneal cavity). A change in the molecular interactions of lipid metabolism (HDL) and angiogenic compounds in endothelial cells increases nitric oxide generation, which enhances blood supply to heterotopies.

Compensatory processes develop at the system level, in the form of a nitrite reductase pathway for the synthesis of nitric oxide, since a

high level of TGF- $\beta$ 1 inhibits NO-synthase. Adaptive reactions in the peritoneal cavity, contributing to a decrease in proliferation and inflammation, are caused by an increase in free cholesterol, LDL and HDL.

In patients with EGE stages III-IV there is relationship between HDL and TNF- $\alpha$  at the systemic level, which has anti-inflammatory properties. In the pancreas of patients of this group the parameters of TGF- $\beta$ 1, nitric oxide metabolites and NO-synthase are significantly increased, which indicates NO-synthase pathway for the synthesis of nitric oxide.

The change in the relationship of the lipid spectrum, nitric oxide metabolites and cytokines is the theoretical basis for additional therapeutic measures aimed at normalizing metabolic processes in EGE.

**RESUMO**

A identidade trigonométrica é importante no aprendizado de matemática, porque exige que os alunos pensem crítica, lógica, sistematicamente e completamente. A resolução de problemas de identidade trigonométrica exige que os alunos relacionem conhecimento conceitual ou conhecimento processual, que depois é usado em perguntas. Este estudo envolveu alunos da série X do ensino médio, que foram examinados para descobrir os tipos de erros de conexão matemática e as causas dos erros. Antes das entrevistas baseadas em tarefas, 36 estudantes foram inicialmente submetidos a um teste. Com base em várias considerações, sete estudantes (três homens e quatro mulheres) foram selecionados para serem submetidos a uma entrevista baseada em tarefas. Esta pesquisa empregou um método qualitativo de pesquisa com desenho de estudo de caso. Os resultados da pesquisa indicam que os erros na conexão com o conhecimento conceitual são mais comumente o erro de conectar o conceito algébrico. Por outro lado, 86,11% dos estudantes experimentaram erros na conexão com o conhecimento processual. Esse erro ocorreu quando os alunos trabalharam em problemas com identidades trigonométricas que raramente encontravam em exercícios. Erros nas conexões matemáticas da identidade trigonométrica são causados pela falta de compreensão da operação aritmética algébrica, ênfase no conceito e conhecimento estratégico. Isso mostra que os alunos precisam de uma variedade de problemas para poderem dominar várias formas de identidades trigonométricas. O resultado desta pesquisa também reforça o importante papel dos conceitos algébricos como conhecimento prévio no estudo da identidade trigonométrica.

**Palavras-chave:** conexão matemática; erro; conhecimento prévio; processual; conceptual**ABSTRACT**

The trigonometric identity is essential in learning Mathematics because it requires students to think critically, logically, systematically, and thoroughly. Solving trigonometric identity problems requires students to relate conceptual knowledge or procedural knowledge, which then used in questions. This study involved grade X students of senior high school, which were examined to find out the types of mathematical connections errors and causes of the errors. Before task-based interviews were conducted, 36 students were first given a test. Based on several considerations, seven students (three males and four females) were selected to undergo a task-based interview. This research employed a qualitative research method with a case study design. The results of the analysis indicate that the errors in connecting to conceptual knowledge are most commonly the mistake of connecting the algebraic concept. On the other hand, 86.11% of students experienced errors in connecting to procedural knowledge. This error happened when the students worked on problems with trigonometric identities, which they had rarely encountered in exercises. Errors in mathematical connections in trigonometric identity are caused by the lack of understanding of the algebraic arithmetic operation, emphasis on the concept, and strategic knowledge. It shows that students need a variety of problems to be able to master various forms of trigonometric identities. This research's result also reinforces the critical role of algebraic concepts as prior knowledge in studying trigonometric identity.

**Keywords:** mathematical connection; error; prior knowledge; procedural; conceptual

## 1. INTRODUCTION:

Trigonometry is one of the earliest mathematics topics that link algebraic, geometric, and graphical reasoning; it can serve as an essential precursor towards understanding pre-calculus and calculus (Weber, 2005). Trigonometric identities play a significant role when students study geometry and calculus at the next level. The essence of learning trigonometric identity is not only knowing its knowledge but also understanding the discovery or derivation of its properties. The trigonometric identities hone students' ability to think deductively, creatively, and practice the problem-solving skill.

During the process of learning mathematics, students need the ability to relate various mathematical concepts as conveyed in Bruner's connectivity theorem, "in mathematics, each concept relates to other concepts." Therefore, students must be allowed to make mathematical connections to be more successful in learning mathematics. Mathematical connections are explained by Hiebert and Carpenter (1992) as part of structured networks such as spider webs, "The junctures, or nodes, can be thought of as pieces of represented information, and threads between them as the connections or relationships." Hiebert and Carpenter attributed the process of conceptualizing the conceptual knowledge to the corresponding structure, which was then highlighted that knowledge only exists when some insight can be interconnected. Also, conceptual understanding can be formed by increasing the number of connections between these pieces of knowledge.

Mathematical connections relate with the connection between one concept to another, one procedure to another, as well as the relationship between facts and procedures, we can see that mathematical connection are related to the ability to link conceptual knowledge and procedural knowledge. Students need both applications of theoretical and procedural knowledge to solve any problem correctly (Taconis, et al., 2000; Cracolice, et al., 2008). Thus, we can divide the mathematical connection errors into two types, namely errors in connecting to conceptual knowledge and errors in connecting to procedural knowledge (Table 1).

Procedural knowledge is a knowledge that focuses on skills and step-by-step procedures without explicit reference to mathematical ideas (Marchionda, 2006). Meanwhile, conceptual knowledge, according to McCormick (1997), relates to the relationship between various

knowledge, so that when students can identify this relationship, it can be said that they have a conceptual understanding. Surf's research (2012) showed that there is a significant relationship between theoretical knowledge and procedural knowledge in solving problems.

The study aimed to find out the types of students' mathematical connections errors and causes of the errors. Insights provided by this research can serve some useful indications such as an error in connecting to conceptual or procedural knowledge, which was done by students and the one that became our particular concern. Besides, it is expected to be useful as an input for teachers about the importance of making mathematical connections for students so that they can be considered in teachers' plans and learning instruction.

## 2. LITERATURE REVIEW:

Many studies have concerned about misconceptions and making errors (Bush, 2011; Dhlamini & Kibirige, 2014; Sarwadi & Shahrill, 2014; Mohyuddin & Khalil, 2016; Ndemo & Ndemo, 2018; Sudihartinih & Purniati, 2020). A few researchers have also mentioned students' misconceptions and errors in trigonometry, such as Orhun (2015) and Usman & Hussaini (2017). Usman & Hussaini's research is based on Newman Error Hierarchical Model, which differs from this research in terms of research method, which was used. Orhun's research is about the difficulties faced by students in using trigonometry for solving problems in trigonometry. Although Orhun studied the students' ability to develop the existing concept in trigonometry, the focus of his research is the trigonometric ratio. On the other hand, Brown (2006) studied students' understanding of sine and cosine. He found out a framework, called trigonometric connection. Although Brown's research was on trigonometric link, the focus of the study was only on the rules of sine and cosine; therefore, this research focuses on trigonometric identity. The identity of trigonometry is one of the topics that high school students should study. Orhun (2015) found that the students did not develop the concept of trigonometry with certainty.

Various literature (NCTM, 2000; Mousley, 2004; Blum, et al., 2007) have identified two main types of mathematical connections. The first is to recognize and apply mathematics to contexts outside mathematics (the relationship between mathematics, other disciplines, or the real world). The second concerns the interconnections

between ideas in mathematics.

Moreover, students can understand mathematics deeply if they have an understanding of conceptual and procedural knowledge (Wilkins, 2000). Conceptual knowledge focuses on understanding the relationship between mathematical ideas and concepts. Meanwhile, procedural knowledge focuses on symbolism, skills, rules, and algorithms that used step by step in completing mathematical tasks. Students must learn the concepts at once with procedures so that they can see the relationship. In line with Wilkins, the NCTM's Principles and Standards for School Mathematics (2000, p. 35) states that developing fluency in mathematical problem solving requires a balance and connection between conceptual understanding and computational ability. The procedures used by the students while solving mathematical problems show the various levels of students' conceptual understanding (Ghazali & Zakaria, 2011). Meanwhile, the issue of conceptual knowledge is a problem experienced even by undergraduate students and prospective teachers (Arjudin, et al., 2016; Dündar & Gündüz, 2017).

### 3. MATERIALS AND METHODS:

#### 3.1. Research methods and participants

Qualitative research method with case study design was used to investigate the grade X students in a high school located in Kartasura, Indonesia. The reason for choosing this school was because the percentage of national examination results on high school trigonometric from 2013-2017 was lower than another topic. Moreover, the results of interviews with teachers indicated that students have difficulty in studying the identity of trigonometry than other issues. Also, the researchers did not teach in the school; it is to minimize the bias of research, which may occur due to the subjectivity of the researchers with students and school staff.

Researchers have received approval to research the school concerned through a letter of agreement signed by the Assistant Principal of Public Relations and Partnership. Moreover, all participants have agreed to participate in this study. Researchers kept their identity to be confidential.

The qualitative approach was appropriate because the analysis of the learners' responses to the given was used to generate theory (Dhlamini & Kibirige, 2014). The case study method was chosen in the hope that through the study of a

somewhat unique individual, valuable insights would be gained (Fraenkel & Wallen, 2000).

#### 3.2. Data collection

This research used task-based interviews that have been used by researchers in qualitative research in mathematics education to gain knowledge about an individual or group of students' existing and developing mathematical knowledge and problem-solving behaviors (Lerman, 2014). The tasks used in this research consists of three items with various degrees of difficulty. It is intended to identify the mathematical connection errors of upper students and anticipate the possibility that only a few students who can answer the questions. Problems given in this research are as follows:

Problem A (for the first test):

- 1) Prove that  $\sec x - \sec x \sin^2 x = \cos x$  !
- 2) Known:
  - $a \cos x + \tan x = \sec x$  and
  - $-b - \tan x = \sec x$ ,
  - determine the simplest form of a.b !
- 3) Prove that  $\frac{\cos x}{1 + \sin x} = \frac{1 - \sin x}{\cos x}$  !

Problem B (for the interview):

- 1) Prove that  $\csc x - \csc x \cos^2 x = \sin x$  !
- 2) Known:
  - $a \sin x + \csc x = \csc x$  and
  - $-b - \csc x = \csc x$ ,
  - determine the simplest form of a.b !
- 3) Prove that  $\frac{\sin x}{1 + \cos x} = \frac{1 - \cos x}{\sin x}$  !

Question number one is a matter of easy category since it only tests students' ability to relate their knowledge of distributive properties (a matter of pre-condition) and then comparing it to the concept of trigonometric identity. Problem number two is a tricky category because it examines the ability of students to identify the relationship between the first equation and the second equation, which can be operated to produce a trigonometric identity formula. So, this problem requires students' ability to relate the concept of arithmetic algebra and then linking the results obtained to the idea of trigonometric identity. Problem number three is a matter of medium category because it tests the ability of students in doing algebraic manipulation that can generate trigonometric identity form associated with the form of trigonometric identity, which will be proven.

Before task-based interviews are conducted, 36 students were given a test first (see Problem A). Task-based interviews are conducted for students who have different content analysis results (different from other students) and fulfill

almost every indicator, based on these considerations, seven students (three males and four females) were selected to undergo a task-based interview. Task-based interviews are carried out to get valid data about errors in mathematical connections that students do and to get data about the causes of failures. Accurate data regarding the purpose of the failure is obtained by conducting interviews at different times.

During the task-based interview, the researchers gave the test to the students in which the problem of the test was similar to the question presented in the previous test (see problem B). The problem is made similar to avoiding the possibility of students memorize the answers. The data were in the form of statements about things done during the fulfillment of tests, errors in making a mathematical connection, causes of mistakes, and guidance from the researcher.

### 3.3. Data analysis

The study used a content analysis technique that was also used by Luneta (2015) when researching students' misconceptions. In this technique, each question is analyzed according to the content they contain (student errors); in this case, the students' answers are indicative of their ability to interact with trigonometric identity questions. The variables measured are their responses (misconceptions and related errors) to the correct answers. The analysis made inferences to the communication (student's answers) by systematically and objectively identifying specific characteristics of the student's errors in the answers. The unit of analysis was the errors students displayed on each questions. Errors made by subjects are grouped and identified its characteristics. Indicators of the type of mathematical connection errors can be expressed in Table 1.

## 4. RESULTS AND DISCUSSION:

The following is the analysis of the mathematical connection error that students do in working on the problem of trigonometric identity along with its causes. A summary of students' errors on the items is provided in Table 2.

In the transcript, the researcher is referred to as R meanwhile, the seven students interviewed are referred to as S.N.2, S.N.5, S.N.6, S.N.12, S.N.1, S.N.33, and S.N.34 which imply the students' serial number in the class. There is also an abbreviation in the figure such as K.S.17.1. K.S

refers to student errors, 17 refers to the serial number of students in the class, and 1 refers to the error number.

### 4.1. Error in mathematical connection problem number 1

#### 4.1.1 Type A

In question number 1, four students include subject number 33, failed in relating knowledge of algebraic arithmetical operations. During the initial test, the student performed a reduction operation on  $\sec x - \sec x \sin^2 x$ , which resulted in  $\sin^2 x$ . When the student was asked to solve a question for a task-based interview, the student redid the same mistake. It can be seen from the quotation I as follows:

Quote I

**S.N.33:**  $\frac{1}{\sin x} - \frac{1}{\sin x} (1 - \sin^2 x)$  results in  $(1 - \sin^2 x)$  because  $\frac{1}{\sin x} - \frac{1}{\sin x}$  the result is zero.

**R:** Look,  $\frac{1}{\sin x}$  multiplied by  $1 - \sin^2 x$ , right?

**S.N.33:** Yeah ...

**R:** Let this  $a$  (the researcher designated  $\frac{1}{\sin x}$ ) minus  $b$  (the researcher pointed  $1 - \sin^2 x$ ) multiplied by  $a$ , what is the result?

**S.N.33:**  $a - ab$

**R:** So, is it true if you write it as this (designate  $\frac{1}{\sin x} - \frac{1}{\sin x} (1 - \sin^2 x)$ )? Is it true if the result is  $1 - \sin^2 x$ ?

**S.N.33:** No ...

According to quote I, the student thought that  $\frac{1}{\sin x} - \frac{1}{\sin x} (1 - \sin^2 x)$  resulted in  $1 - \sin^2 x$ . It shows that the student failed in relating the concept of algebraic form calculation, which had been learned in junior high school to be applied to this problem. That algebraic form contains fractions, Bush (2011) in his research, showed that students often applied the wrong algorithm when adding, subtracting, multiplying, or dividing fractions. When the researcher simplified the algebraic form, the student was able to answer the researcher's question correctly. So, this error occurred since the student did not understand the concept of algebraic arithmetic operations. Problems regarding understanding algebraic concepts are problems that have attracted the attention of many researchers (House & Telese, 2008; Nathan & Koellner, 2007; Bush, 2011; Pournara, et al., 2016), this suggests that the notion of algebraic concepts are things that are commonly experienced by students. The results of

this research, which focuses on trigonometric identities, also found students who lacked understanding of algebraic concepts; this finding supports the research of Usman & Hussaini (2017) which focused on the manipulation of trigonometrical ratios using formula and the right-angled triangle. They noted that the students' error in solving trigonometrical problems was due to their weaknesses in basic arithmetical operations.

#### 4.1.2 Type B

In question number 1, four students failed in relating their knowledge about distributive properties to change an algebraic form. One of four students who experienced this failure is subject 33, as seen in the following quotation II:

Quote II

**R:** In this " $a - ab$ " form ( $a$  stands for  $\frac{1}{\sin x}$  and  $b$  stands for  $(1 - \sin^2 x)$ ), can you change its shape based on its distributive properties? (Students were asked to change " $a - ab$ " form into " $a(1 - b)$ " form)

**S.N.33:** Yes ..... it becomes  $a - b$ .

**R:** Really? If we apply distributive properties to this form, it will become " $a$ ". Then, what is inside the bracket?

**S.N.33:** Uh, it becomes 1.

**R:** Okay, 1 and then?

**S.N.33:** Minus  $b$ .

The student cannot explore her cognitive ability about distributive properties on  $\frac{1}{\sin x} - \frac{1}{\sin x} (1 - \sin^2 x)$  becomes  $\frac{1}{\sin x} (1 - (1 - \sin^2 x))$  or becomes  $\frac{1}{\sin x} - \frac{1}{\sin x} + \frac{1}{\sin x} \cdot \sin^2 x$ . It indicates that the student has failed to relate her prior knowledge. Gentile & Lalley (2003) revealed that the mastery of prior knowledge was required by students in the study of mathematics, it is an important step in concept development. This happens because the learning process in Mathematics is categorized as a widely related hierarchical learning process (Usman & Hussaini, 2017). If prior knowledge or skills do not exist, the task of learning becomes more difficult, if the prior knowledge has been wrongly understood, the need to learn a new topic results in students for getting previous misconceptions.

Based on quote I, students still encounter difficulties and need guidance from the researcher to apply distributive properties although  $\frac{1}{\sin x} -$

$\frac{1}{\sin x} (1 - \sin^2 x)$  has been simplified its algebraic form into  $a - ab$ . Thus, we can conclude that the cause of these errors is the inability to apply their basic knowledge of distributive properties to new situations. Mulungye, et al. (2016) stated that the distributive property says that  $a(b + c) = ab + ac$ . Therefore, students use this rule in new situations that are not appropriate. The distributive properties of the multiplication toward the sums are memorized in their minds that they intuitively misapplied them to a similar situation.

Students also failed to relate their knowledge about  $1 - \sin^2 x = \cos^2 x$ , which was then applied to question number 1. The four students use similar methods in solving problems. They changed  $\sec x$  to  $\frac{1}{\cos x}$ , during the first test, but all four students made a mistake when changing the form of  $\csc x$  in the second test. The students did not know that another form of  $\csc x$  is  $\frac{1}{\sin x}$  although the researcher had tried to guide them; so, they still cannot answer the question correctly. The fact that they can change  $\sec x$  to  $\frac{1}{\cos x}$ , but cannot change  $\csc x$  to  $\frac{1}{\sin x}$  Indicates that they memorize the similarities that exist in trigonometric identities. Tobias (1993) stated that mathematical anxiety can cause a person to forget. This is consistent with the results of further interviews; the subject number 34 said that he felt depressed and considered the topic confusing, this anxiety caused him to forget the trigonometry identities. Mathematical anxiety is a feeling of tension and anxiety that interferes the manipulation of numbers and solving mathematical problems in various academic situations and everyday life. Some students tend to experience this anxiety in exams. Meanwhile, others are only afraid of mathematical calculations. Wells (1994) identified anxiety as a significant factor that hinders students' reasoning, memory, understanding of general concepts, and respect to Mathematics.

#### 4.2. Error in mathematical connection problem number 2

##### 4.2.1 Type A

As many as 44.4% of students failed to relate their knowledge about the concept of algebraic operation, especially in trigonometric identities. Students concluded that if  $1 - \sin^2 x = \cos^2 x$  then  $1 - \sin x = \cos x$ . The student thought that  $\sqrt{1} = \sqrt{\sin^2 x + \cos^2 x}$  produces  $1 = \sin x + \cos x$ . Students considered that the square root function was linear. Students tend to over-regenerate what has been experienced as

something 'true' (De Bock, Van Dooren, Janssens, & Verschaffel, 2002)

The failure to relate knowledge of algebraic arithmetic operations also occurred when changing the form of  $a \cos x + \tan x = \sec x$  into  $a = -\cos x - \tan x + \sec x$ . This error occurred since the student did not understand the concept of addition, reduction, and multiplication, which are operated together. The researcher found that when the algebraic form was still in a complicated form, the students were not able to cope, but when the algebraic form was already in a simple form, the students were able to overcome it. Researchers found that students can overcome errors in connecting the concept of algebraic operations when researchers simplify the algebraic form. The student was able to answer the question and followed the direction given by the researcher when the researcher simplified the algebraic form and gave direction to him. Thus, the cause of this error was that the students do not understand the concept of algebraic operation. The findings of this research support Norasiah's research (2002) which noted that most average students faced difficulty in performing trigonometrical operations.

#### 4.2.2 Type B

As many as 52.78% of students did not try to associate trigonometric identities with other trigonometric identities. Still, they chose to elaborate trigonometric identity formulas, which lead to more complex counting operations. If the student was able to handle such complexity as student number 26, he would achieve the simplest form. If the student was unable to handle it, he would have difficulty in finding the most straightforward way; it is experienced by subject number 17 (Figure 1).

When the students were asked to work on similar problems and then interviewed about the results of their work, they reused this strategy. It can be seen in the following quotation III

Quote III

**R:** Why did you choose this strategy? Did you elaborate each of these identities?

**S.N.17:** If it was not elaborated, the answer would not be the simplest one ...

**R:** Oohh... like that ... do you know the identity which has something to do with  $\csc x$  and  $\cot x$ ? Something with a quadratic form?

**S.N.17:** Yes ...

**R:** What is it?

**S.N.17:** Cosecant  $x$  is equal to one per sinus  $x$

**R:** No ...something about  $\csc^2 x$ ...

**S.N.17:**  $\csc^2 x = \frac{1}{\sin^2 x}$

**R:** No...cosecant  $x$  is connected with cotangent  $x$ ...

**S.N.17:** I forgot ...

**R:** Do you ever think about this? This is  $\cot x$ , and this is  $\csc x$ ; then, its  $b$  is also there  $\cot x$ ,  $\csc x$  ... then you look for  $a$  itself... $b$  itself which were then sought the relationship between the two?

**S.N.17:** No ...It is hard to think.

Handwritten mathematical work of subject number 17. The work is divided into several sections labeled K.S.17.1, K.S.17.2, K.S.17.3, and K.S.17.4. K.S.17.1 shows the derivation of  $a = \sec x$  from  $a \cos^2 x + \sin x = 1$ . K.S.17.2 shows the derivation of  $b = \frac{1 + \sin x}{-\cos x}$  from  $-b \cos x - \sin x = 1$ . K.S.17.3 shows the calculation of  $a \cdot b = \frac{1 + \sin x}{-\cos^2 x}$ . K.S.17.4 shows the final result  $a \cdot b = \frac{1 + \sin x}{-\cos^2 x}$ .

**Figure 1.** The response of subject number 17

Based on the quotation III, it indicates that the student failed to associate his knowledge about  $\sec^2 x - \tan^2 x = 1$ , which was then applied to the results of multiplication  $a$  and  $b$ . It happened because the student thought that a simple form would be achieved if each trigonometric identity was altered. The selection of such strategy resulted in complicated calculations; in this case, student number 17 was not able to overcome the complexity, which resulted in a miscalculation (see K.S.17.3 in Figure 1). Wright (2014) stated that students need the ability to choose the applicable formula based on the context of the mathematical problems they encounter.

As many as 5.6% of students chose the strategy of eliminating the system of equations, which caused some more complex counting operations. Although the students tried to solve this problem by linking their knowledge of

elimination rules, this strategy is not appropriate. It indicates that the students did not understand the concept that the two equations are not linear equations (error type A). Although the students could change the equations in the form of linear equations, the number of unknown factors was more than the sum of the equations. It caused the system of linear equations not to have a solution. If it had a solution, it would have an infinite number of solutions. Besides, the student also failed to associate the fact that  $\sec^2 x - \tan^2 x$  is equal to 1 (error type B). One of the students using this strategy was student number 6, as seen in the following quotation IV:

Quote IV

**R:** Why did not you try another strategy to solve this problem? Such as determining the value of  $a$  and  $b$  first, then doing the multiplication operation towards  $a$  and  $b$ ?

**S.N.6:** Uumm ...I did not think like that.

**R:** Was it because there were two equations, then you chose to eliminate them?

**S.N.6:** Yes... if there are two equations, I solve it by elimination.

Based on quote IV, it shows that the student eliminated both equations (see K.S.6.1 and K.S.6.2 in Figure 2). The cause was the student's lack of understanding of the concept of the linear equation system. The student assumed that two equations had to be solved by elimination. The choice of such a strategy resulted in more complicated calculations. In this case, subject number 6 was not able to overcome the complexity which occurred (see K.S.6.3 and K.S.6.4 in Figure 2) due to complicated forms, resulting in the student making errors in the calculations.

The figure shows handwritten mathematical work for subject number 6. It includes several boxed sections labeled K.S.6.1, K.S.6.2, K.S.6.3, and K.S.6.4. K.S.6.1 shows two equations:  $a \cos x + \tan x = \sec x$  and  $-b - \tan x = \sec x$ , which are then manipulated. K.S.6.2 shows a similar manipulation. K.S.6.3 and K.S.6.4 show increasingly complex algebraic expressions involving trigonometric functions and fractions, resulting from the elimination process.

**Figure 2.** The response of subject number 6

Based on the results of the analysis on students number 6 and 17, it shows that the

students did not have good ability to relate one trigonometric identity with other trigonometric identities. Based on the interview, all students who made mistakes in number 3 did not know the identity value of the  $\sec^2 x - \tan^2 x$ , even though, based on observations, the teacher has given detailed knowledge about  $\sec^2 x - \tan^2 x = 1$ . However, the teacher did not provide enough emphasis on this identity. The given problem was less varied. It only focused on the relationship of  $\sin^2 x + \cos^2 x = 1$ . In this case, the researcher assumed that the cause of the student's error in relating his knowledge of  $\sec^2 x - \tan^2 x = 1$  to be used in the results of multiplication  $a$  and  $b$  was the lack of emphasis on the concept and lacking of strategic knowledge. This is in accordance with the results of Lopez's (1996) study which focuses on mathematical word problems, he also found that weakness in understanding concepts and lacking of strategic knowledge result in difficulties in problem-solving. Moreover, students who were weak in conceptual understanding were found to lack arithmetic and procedural skills (Narayanan, 2007).

#### 4.3. Error in mathematical connection problem number 3

##### 4.3.1 Type B

Some students failed to relate their knowledge of multiplication to convert  $1 + \cos x$  into  $1 - \cos^2 x$ . Based on the interview result, it shows that the student already knew that he had to use the fact that  $1 - \cos^2 x$  is equal to  $\sin^2 x$  to solve this problem. However, the student could not exploit his cognitive ability to change  $1 + \cos x$  into  $1 - \cos^2 x$ . It indicates that the student failed in relating his knowledge of multiplication with a conjugate pair. The student already knew which identity formula should be utilized after getting directions from the researcher. However, the student did not know how to direct  $1 + \cos x$  to be converted into  $1 - \cos^2 x$ . So, the cause of student's error was less skill in doing the algebraic manipulation.

The error which occurred in problem number 3 is classified as minimal since only seven students who experienced this problem. Moreover, no student experienced error type B on this problem. Based on the observation done by the researcher, the teacher has given practice and provided a discussion on this kind of problem. Besides, some problems with the students' worksheets also honed their ability to solve this kind of problem. If the students are accustomed to solving certain types of problems, they will be able to solve other problems that are similar in types; it

is because the students already understand the way of settlement. A question or a mathematical problem is said to be a problem if the person who faces the challenge feels the gap between where it is and where it should be but do not know how to cross the deficit, this results in difficulties in solving existing problems (Reid & Yang, 2002).

## 5. CONCLUSION:

The results of this study have provided a new description of the error of mathematical connections in solving trigonometric identities. There are two types of mathematical connection errors. The first one is errors in connecting to conceptual knowledge (type A), and the second one is errors in connecting to procedural knowledge (type B). Students most commonly do error type A is the mistake of connecting the algebraic concept. Although the percentage is small, we can see that in-depth conceptual understanding of the linear equation system can cause connection errors in trigonometric identity problem solving.

In the second type (type B), an error occurred most often when the students worked on problems with trigonometric identities, which they had rarely encountered in exercises; 86.11% of students experienced this error. If the given problem contained common trigonometric identities encountered in their daily practice, only 30.56% students experience connection errors, from this fact, we could include that the second type of error was caused by the lack of emphasis on the concept and lack of strategic knowledge. Errors committed by the students in learning trigonometry can be useful for the teachers in evaluating their teaching as well as being able to correct the students' works appropriately.

## 6. LIMITATION AND STUDY FORWARD:

In this paper, we just discussed the error of mathematical connections in solving trigonometric identities. For the next researcher can discuss the topics more widely.

## 7. ACKNOWLEDGEMENTS:

The authors thank to Kartosuro Senior High School for giving research permission. We also thank to Universitas Sebelas Maret Surakarta for budget supporting. The authors are grateful to the reviewers for helpful comments.

**Table 1. Indicators for Types of Mathematical Connection Errors**

| No. | Type of Mathematical Connection Errors                | Indicators  |
|-----|---|---|
| 1   | Errors in connecting to conceptual knowledge (Type A) | Applying the concept of calculation incorrectly<br>Using concepts to prior knowledge inappropriately  |
| 2   | Errors in connecting to procedural knowledge (Type B) | Using improper trigonometric rules or formulas<br>Making a mistake/ unable to do algebraic manipulation<br>Making sign errors in count operations |

**Table 2. Percentage of Students' Failures on Each Item**

| Item |        | Description of errors   | Percentage of students' errors |
|------|--------|---|--------------------------------|
| 1    | Type A | Relating knowledge of algebraic arithmetical operations (eg. $\frac{1}{\sin x} - \frac{1}{\sin x}(1 - \sin^2 x)$ produces $1 - \sin^2 x$ )  | 5.56                           |
|      | Type B | Relating their knowledge that $1 - \sin^2 x$ is equal with $\cos^2 x$   | 13.89                          |
|      |        | Relating distributive properties to change an algebraic form  | 8.33                           |
| 2    | Type A | Relating their knowledge of the algebraic rule (e.g. conclude that $\sqrt{1} = \sqrt{\sin^2 x + \cos^2 x}$ produces $1 = \sin x + \cos x$ ) | 44.44                          |
|      |        | Relating their knowledge of the algebraic rule ( $a \cos x + \tan x = \sec x$ into $a = -\cos x - \tan x + \sec$ )                          | 38.89                          |
|      |        | Relating their knowledge about the concept of linear equation system  | 5.56                           |
|      | Type B | Relating their knowledge that $\sec^2 x - \tan^2 x$ is equal with 1   | 52.78                          |
|      |        | Relating distributive properties to change an algebraic form  | 11.11                          |
| 3    | Type B | Relating their knowledge of multiplication with conjugate pair to change an algebraic form  | 11.11                          |

## APPENDIX

### INTERVIEW GUIDELINES

#### The purpose of the interview

Obtain information about student mathematical connection errors in solving trigonometric identity problems and obtain information about the causes of these difficulties.

#### Interview Conditions

1. The questions adapted to the problem-solving conditions of the students (writing and explanation)
2. If students have difficulty to understand certain questions, the interviewer can provide a guide to simpler questions without reducing the gist of the problem.

#### Interview Implementation

1. Provide trigonometric identity test questions.
2. Ask students to read the test questions carefully. Make sure students understand each question and give students time to work on it.
3. To dig up data regarding errors in connecting to conceptual knowledge (Type A) is done with
  - a. Asking main questions on the subject, for example, "What is the reason you get this final result?"
  - b. Give follow-up questions so that you can explore the information processing done by the subject in detail when using concepts in initial knowledge, for example, "In this section, how do you/ what reasons do you get results like this?"
  - c. Give follow-up questions so that you can explore the information processing carried out by the subject in detail when applying the concept of calculation, for example, "Please pay attention to the calculations in this section, is there a miscalculation?"
4. To dig up data regarding errors in connecting to procedural knowledge (Type B) done with
  - a. Asking main questions on the subject, for example, "How will you solve the problem?"
  - b. Give follow-up questions so that you can explore the information processing done by the subject in detail at the stage of determining trigonometric rules or formulas, for example, "What are the trigonometric identities that you use to solve the problem?"
  - c. Give follow-up questions so that you can explore the mistakes made by the subject in detail, for example, "How do you change this algebraic form into another algebraic form?"
  - d. Give follow-up questions so that you can explore the sign mistake made by the subject in detail, for example, "Is the sign of the operation/operation of your calculation correct?"

### RESUMO

A resistência bacteriana é um crescente desafio enfrentado pelos cientistas de design de medicamentos para encontrar novos medicamentos ou atualizar o antibiótico comumente usados. O objetivo deste estudo foi sintetizar, estruturar e destacar características biológicas de novas espécies de complexos metal-orgânicos  $[(MCl_2)_2L_1]$   $\{M = Ni, Cu, L_1 = N, N'-1, 4\text{-Fenilenobis (metanililideno) bis (etano-1,2-diamina)}\}$  e  $[(NiCl_2)_2L_2]$ . Os ligantes da base de Schiff foram preparados em excelentes campos, adicionando tereftalaldeído a 1,2-etano-diamina ou 1,4-butano-diamina. Três complexos binucleares de metais básicos de Schiff foram sintetizados em uma reação simples de um reator por reação dos sais correspondentes de cloreto de metal ( $NiCl_2$  e  $CuCl_2$ ) com os ligantes da base de Schiff  $\{L_1 = N, N'-(1,4\text{-fenilenobis (metanililideno) bis (1,2-dietilamina)})$  e  $L_2 = N, N'-(1,4\text{-fenilenobis (metanililideno) bis (butano-1,4-diamina)})\}$ . Os complexos de metal base schiff obtidos foram caracterizados analiticamente por um conjunto de técnicas espectroscópicas, tais como espectroscopia FT-IR, espectros de RMN de  $^1H$  e espectros de massa. Os estudos de caracterização de estruturas sugerem que os ligantes da base de Schiff se comportam como ligantes bidentados N para centros de metal de níquel e cobre que são conhecidos por atuarem como ácidos de Lewis. A atividade biológica da base Schiff dos complexos de níquel (II) e cobre (II) foi testada usando o método de diluição em caldo. Os complexos mostraram atividade antibacteriana contra todas as bactérias gram-negativas e gram-positivas (*Enterobacter cloacae* G-, *Citrobacter* G-, *Pseudomonas* G-, *Klebsiella* G-, *Staphylococcus* G + e *Streptococcus* G +) utilizadas nos ensaios. Conclui-se que os complexos de metais básicos de Schiff são um bom candidato ao medicamento antibacteriano devido à sua boa atividade contra cepas gram-negativas e gram-positivas demonstradas no presente estudo, bem como em outros estudos na literatura.

**Palavras-chave:** atividade antibacteriana, organometálica, complexos, síntese, espectroscópica.

### ABSTRACT

Bacterial resistance is a growing challenge facing drug design scientists to find new medications or update commonly used antibiotics. The objective of this study was to synthesize, structure and highlight biological features of new species of metal-organic complexes  $[(MCl_2)_2L_1]$   $\{M = Ni, Cu, L_1 = N, N'-1,4\text{-Phenylenebis(methanylylidene)bis(ethane-1,2-diamine)}\}$  and  $[(NiCl_2)_2L_2]$ . The Schiff base ligands were prepared in an excellent yeilds by adding terephthalaldehyde to 1,2-ethane-diamine or 1,4-butane-diamine. Three binuclear Schiff base metal complexes were synthesized in a simple one-pot reaction by reacting the corresponding metal chloride ( $NiCl_2$  and  $CuCl_2$ ) salts with the Schiff base ligands  $\{L_1 = N, N'-(1,4\text{-phenylenebis(methanylylidene)bis(1,2-diethylamine)})$  and  $L_2 = N, N'-(1,4\text{-phenylenebis(methanylylidene)bis(butane-1,4-diamine)})\}$ . The obtained Schiff base metal complexes were analytically, characterized by a set of spectroscopic techniques such as FT-IR spectroscopy,  $^1H$  NMR spectra, and mass spectra. The structures characterization studies suggest that Schiff base ligands behave as N bidentate ligands for nickel and copper metal centers, which are known to act as Lewis acids. The biological activity of the Schiff base of nickel(II) and copper(II) complexes was tested by using the broth dilution method. The complexes showed antibacterial activity against all gram-negative and gram-positive bacteria (*Enterobacter cloacae* G-, *Citrobacter* G-, *Pseudomonas* G-, *Klebsiella* G-, *Staphylococcus* G+, and *Streptococcus* G+) that used in the trials. It is concluded that Schiff base metal complexes are a good candidate for the antibacterial drug because of its good activity against gram-negative and gram-positive strains demonstrated in the present study, as well as in other studies in the literature.

## 1. INTRODUCTION:

Schiff bases are an essential ligand system in developing coordination chemistry due to their tunable and chelating properties (Radha et al., 2018). Chelating ligands containing O, N, and S donor atoms are well known as having a broad biological activity (Shi et al., 2007). Moreover, this activity can be increased when such ligands are bonded to a metal ion (Chohan et al., 2007; Tsapkov et al., 2008).

Intensive studies have been reported on the biological activity of Schiff bases like antibacterial (Panneerselvam et al., 2009; Rai, and Kumar, 2013), antifungal (Ramesh and Maheswaran, 2003), antitumor (Liu et al., 1992), antiviral (Kumar et al., 2010), anti-HIV (Vicini et al., 20103), herbicides (Holla et al., 2000), insecticides (Alcock et al., 1980) and anti-influenza virus (Zhao et al., 2011). In addition, a wide range of applications have been reported in food and dye industries, analytical chemistry, catalysis, agrochemical, and anti-inflammable and antiradical (Kuddushi et al., 2018). Furthermore, anti-corrosion properties were also investigated (Shaju et al., 2014).

The importance of Schiff bases and their metal complexes was also demonstrated in electrochemical (Neelakantan et al., 2010) and redox catalysis (Vedanayaki et al., 2010; Canpolat, and Kaya, 2004). The role of chlorophyll, hemoglobin, carbonic anhydrase, vitamin B12, xanthine oxidase, and hemocyanin, illustrates the intimate linkage between inorganic chemistry and biology (Singh and Bhatnagar, 2004).

This study aimed to explore the antimicrobial activity of Schiff base metal complexes against six different strains of gram-negative and gram-positive bacteria (*Enterobacter cloacae* G-, *Citrobacter* G-, *Pseudomonas* G-, *Klebsiella* G-, *Staphylococcus* G+, and *Streptococcus* G+).

## 2. MATERIALS AND METHODS:

### 2.1. Chemical materials

All chemicals were of analytical reagent grade, purchased from Sigma-Aldrich and used without further purification. FT-IR spectra (KBr

matrix) (4000-200  $\text{cm}^{-1}$ ) were recorded on an FT-IR Spectrometer Model C103 (Shimadzu).  $^1\text{H}$  NMR spectra were obtained on a Varian 400 NMR spectrometer and recorded in DMSO- $d_6$ . Chemical shifts ( $\delta$ ) are expressed in parts per million downfield using tetramethylsilane as an internal reference or by using the residual protonated solvent. Mass spectra of the compounds were recorded on an Agilent Technologies (HP) 5973 Network Mass Selective Detector. NMR and Mass analyses were performed at the Central Instrumental Lab., School of Chemistry, College of Science, University of Tehran, Enghelab St., Tehran, Iran.

### 2.2. Ligands synthesis

The condensation reaction (Vinita et al., 2013) was employed to synthesize Schiff base ligands  $L_1$  and  $L_2$ . Initially, terephthalaldehyde (0.13 g, 1 mmol) and 1,2-ethane-diamine (0.12 g, 2 mmol) or 1,4-butane-diamine (0.17 g, 2 mmol) were dissolved in 25 mL methanol in a 50-mL round-bottomed flask equipped with a condenser (Equations 1 and 2). The reaction mixture was stimulated by droplets of acetic acid, refluxed, and stirred for 4 h, then cooled, filtered, and dried in a desiccator over anhydrous  $\text{CaCl}_2$  and recrystallized from methanol. Orange powder of  $L_1$  was obtained (Yield = 0.20 g, 80%, m.p. = 265-267  $^\circ\text{C}$ ) or white powder of  $L_2$  (Yield = 0.25 g, 83%, m.p. = 241-243  $^\circ\text{C}$ ).

Equation 1

**Equation 2**

### 2.3. Schiff base metal complexes synthesis

$NiCl_2$  and  $CuCl_2$  salts were reacted with Schiff base  $L_1$  or  $L_2$  to form the following solid complexes  $[(NiCl_2)_2L_1]$ ,  $[(CuCl_2)_2L_1]$  and  $[(NiCl_2)_2L_2]$  (**Scheme 1**). These complexes were prepared by addition of (2 mmol, 0.25 g)  $NiCl_2$  or (2 mmol, 0.26 g)  $CuCl_2$  in about 25 mL of hot ethanol to a solution of (1 mmol, 0.21 g)  $L_1$  or (1 mmol, 0.27 g)  $L_2$  Schiff bases in about 15 mL ethanol with continuous stirring. The reaction mixture was refluxed for 4 h. Colored complexes were filtered, washed with methanol, and dried in a vacuum desiccator (Mishra et al., 2015; Salehi et al., 2016; Nagesh and Mruthyunjayaswamy, 2015).

### 2.4. Biological activity

The antibacterial activity of the chemical compounds  $[(NiCl_2)_2L_1]$  (**1**),  $[(CuCl_2)_2L_1]$  (**2**) and  $[(NiCl_2)_2L_2]$  (**3**) was *in vitro* screened using the disc diffusion method (CLSI, 2010). The strains were treated with compounds **1**, **2**, **3** and a ligand, which were dissolved in DMSO. The biological activity of these compounds was tested against a set of pathogenic gram-negative and gram-positive bacteria, respectively, *Enterobacter cloacae* G-, *Citrobacter* G-, *Pseudomonas* G-, *Klebsiella* G-, *Staphylococcus* G+, and *Streptococcus* G+. Sterilized needles were used to transfer the required microorganisms to the nutrient agar. Amoxicillin and Azithromycin (10 mg mL<sup>-1</sup>) were used as reference drugs, DMSO was used in the measurement as a control. The diffusion was done by placing plates at room

temperature for 1 h and incubated at 37 °C for 24 h. A scale was used to measure the inhibition diameters of the clear zone. Minimum inhibitory concentration (MIC) studies of the prepared Schiff base complexes lead to promising antimicrobial activity. The Microwell dilution technique (CLSI, 2012) was employed to determine the minimum inhibitory effect of the Schiff base, and its metal complexes and Muller-Hinton (Ansari et al., 2011) broth was used as culture media. Complexes (**1-3**) were prepared with 1000 mg mL<sup>-1</sup> and the discs were incubated at 50°C for 30 min to increase solubility.

## 3. RESULTS AND DISCUSSION:

Schiff base metal complexes described above (**Scheme 1**) were synthesized by the direct reaction between the ligands ( $L_1$ ,  $L_2$ ) and ( $NiCl_2$ ,  $CuCl_2$ ) in 1:2 molar ratio in ethanol. All the complexes showed a high level of stability at room temperature (25 °C) while the solubility in some organic solvents was limited, except in DMSO. The solubility difficulties of complexes **1-3** did not allow us to perform single-crystal X-ray diffraction analysis in this study for structure elucidation. Thus, all ligands and their complexes were diagnosed according to the results of a set of accurate analysis.

### 3.1. $[(NiCl_2)_2L_1]$ (**1**)

A metathesis reaction between  $NiCl_2$  and  $L_1$  (**Scheme 1**) led to the formation of complex (**1**) in good yield (0.18 g, 85 %, m.p. 243-245 °C).

### 3.2. $[CuCl_2)_2L_1]$ (**2**)

Similar product (**2**) with an excellent yield (0.19 g, 90 %, m.p. 237-239 °C) was obtained starting from  $CuCl_2$  and  $L_1$ .

### 3.3. $[(NiCl_2)_2L_2]$ (**3**)

The complex **3** was prepared by following the same described route for complexes **1** and **2**, resulting in a moderate product yield (0.17 g, 62 %, m.p. 246-248 °C).

### 3.4. FT-IR spectra

FT-IR spectra analysis of the Schiff base ligands  $L_1$  and  $L_2$  show strong bands, respectively, at 1643 and 1635 cm<sup>-1</sup>, assigned to azomethine  $\nu(C=N)$  group confirming the success of ligand synthesis. The shift toward higher or lower frequencies is a common trend in coordination chemistry due to the association of the metal ions

with the azomethine group with a symmetric ring. The nature of the metal ion and the associated atoms and bonds can shift the frequencies toward higher or lower values. Spectra of compounds **1**, **2** and **3** also showed the disappearance of the band attributed to carbonyl (C=O) group of aldehydes, the starting material, confirming the success of ligand synthesis. Schiff bases metal complexes (**1-3**) were also characterized by the appearance of bands at the region 2939, 3387, and 3302  $\text{cm}^{-1}$  respectively, due to the  $\tilde{\nu}(\text{C-H})$  aromatic vibrations.

#### 3.4.1 $[(\text{NiCl}_2)_2\text{L}_1]$ (**1**)

The following IR bands were observed in **Figure 1** at  $\tilde{\nu}$  equal to: 3541 (w), 2939 (w), 2839 (s), 2110 (m), 1697 (w), 1643 (s), 1550 (w), 1442 (s), 1350 (m), 1296 (s), 1211 (m), 1111 (m), 1049 (w), 1002 (m), 964 (m), 918 (w), 871 (w), 833 (s), 686 (s), 524 (w), 462 (w), 393 (s), 316 (m), 270 (m). In comparison with the spectra of the Schiff bases ligand, the  $\tilde{\nu}(\text{C=N})$  band exhibits an upward shift to 1697  $\text{cm}^{-1}$ , which is in agreement with the azomethine group that coordinated to the metal ion, as previously reported (Das et al., 2014). The strong band that appeared at 1643 was assigned to C=C stretching. Moreover, medium intensity bands that appear at 3541 (w)-2839 (w)  $\text{cm}^{-1}$  assigned to  $\tilde{\nu}\text{NH}_2$  group proved the M-NH<sub>2</sub> coordination (Khan et al., 2016). Furthermore, the appearance of medium intensity bands at the range 678- 316  $\text{cm}^{-1}$  attributed to  $\tilde{\nu}(\text{M-N})$  vibrations is another evidence that confirms the coordination between the ligand and the metal atoms through the azomethine nitrogen atom. The strong and medium two bands appeared at 1442 (s) and 1350 (m) were attributed to CH<sub>2</sub> deformation vibrations (Khan et al., 2017; Bhattacharyya et al., 2015).

#### 3.4.2 $[\text{CuCl}_2)_2\text{L}_1]$ (**2**)

The following IR bands were observed in **Figure 2** at  $\tilde{\nu}$  equal to: 3302 (m), 3232 (m), 3124 (w), 3024 (w), 2916 (m), 2854 (m), 1697 (s), 1635 (s), 1450 (s), 1365 (s), 1280 (s), 1203 (s), 1111 (m), 1010 (s), 972 (m), 840 (s), 678 (m), 532 (s), 432 (s), 362 (w), 339 (w), 277 (m). The compound  $[(\text{CuCl}_2)_2\text{L}_1]$  (**2**) showed two strong bands that shifted upward assigned to the  $\tilde{\nu}(\text{C=N})$  group of the azomethine function, as previously reported (Das et al., 2014). The intense band that appeared at 1635 was assigned to C=C stretching. Comparing with the previously reported complexes (Khan et al., 2016), the bands observed at 3302 (m), and 3024 (w)  $\text{cm}^{-1}$  clearly confirm the M-NH<sub>2</sub> coordination. Methylene (CH<sub>2</sub>)

deformation vibrations are responsible for the two bands appeared at 1450 (s) and 1365 (s). IR spectrum of compound  $[\text{CuCl}_2)_2\text{L}_1]$  can provide further support to confirm the coordination by the presence of bands at the range from 678 (m) to 277 (m)  $\text{cm}^{-1}$ , related to  $\tilde{\nu}(\text{M-N})$  vibrations (Khan et al., 2017; Bhattacharyya et al., 2015).

#### 3.4.3 $[(\text{NiCl}_2)_2\text{L}_2]$ (**3**)

The following IR bands were observed in **Figure 3** at  $\tilde{\nu}$  equal to: 3595 (w), 3387 (w), 3024 (w), 2939 (s), 2839 (s), 2060 (w), 1697 (s), 1635 (s), 1458 (s), 1342 (s), 1296 (s), 1211 (s), 1095 (w), 1049 (w), 1002 (m), 964 (m), 918 (w), 825 (s), 740 (w), 678 (w), 516 (s), 385 (w), 331 (w), 270 (w). The  $\tilde{\nu}(\text{C=N})$  at 1697 (s)  $\text{cm}^{-1}$  for compound  $[(\text{NiCl}_2)_2\text{L}_2]$  (**3**), at higher frequencies compared to the spectrum of the Schiff base ligand confirms the coordination to the metal ion (Das et al., 2014). Aromatic C=C stretching originated the band at 1635. Moreover, the prove of M-NH<sub>2</sub> coordination can simply be highlighted by the appearing of bands at 2939 (s)-2060 (w)  $\text{cm}^{-1}$ , following previously reported complexes (Khan et al., 2016). Two sharp bands appeared at 1458 (s), and 1342 (s) were attributed to (CH<sub>2</sub>) deformation vibrations. Further comparison with reported structures (Khan et al., 2017; Bhattacharyya et al., 2015) proves the M-NH<sub>2</sub> coordination by another clear evidence, which is the appearance of  $\tilde{\nu}(\text{M-N})$  vibrations in the range from 678 (w) to 270 (w)  $\text{cm}^{-1}$ .

#### 3.5. <sup>1</sup>H NMR spectra

<sup>1</sup>H NMR spectra of the complexes (**1** and **2**) were recorded at room temperature in DMSO and interpreted using TMS as an internal reference, while <sup>1</sup>H NMR spectrum could not be obtained for compound (**3**) due to its poor solubility in DMSO. The spectrum of the DMSO as a solvent has been zeroed. The <sup>1</sup>H NMR spectra of compounds (**1**) and (**2**) are given in **Figures 4** and **5**, respectively. The behavior of compounds (**1** and **2**) in solution is an important indicator of the complexation since the characteristic signals of the free ligand have suffered noticeable changes after complexation. <sup>1</sup>H NMR spectra of azomethine group of all complexes show signals shifted to the down field as a result of the coordination between the metal ion and the ligand. This shifting toward downfield is caused by the deshielding of protons as it is well-known; its electron density is reduced after coordination (Silva et al., 2008). The chemical shift detected for the NH<sub>2</sub> group in the ligand was not observed in any of the complexes (**1**) and (**2**).

### 3.5.1 [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] (1)

The <sup>1</sup>H NMR (400 MHz, DMSO, 25°C) peaks are observed at δ/ppm equal to: 8.21 (s, 2H, CH=N-), 8.00-7.49 (m, 4H, Ar), 2.50, 3.33 (8H, CH<sub>2</sub>), 1.09 (d, 4H, NH<sub>2</sub>). The formation of the Ni Schiff base complex [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] was further confirmed by the NMR spectrum. The <sup>1</sup>H NMR spectrum given in **Figure 5** showed multiple small signals in the aromatic region (7.49 - 8.00 ppm) related to the phenyl aromatic protons and the integration of these signals corresponds to the composition of the compound. The spectrum also showed the appearance of two triplets in the region between 2.50 and 3.33 ppm attributed to the methylene groups. Chemical integrations show that the singlet at (8.21 ppm) is related to azomethine.

### 3.5.2 [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] (2)

The <sup>1</sup>H NMR (400 MHz, DMSO, 25°C) peaks are observed at δ/ppm equal to: 10.14 (d, 2H, CH=N-), 8.12-7.80 (m, 4H, Ar), 2.50, 3.40 (8H, CH<sub>2</sub>), 1.21 (t, 4H, NH<sub>2</sub>). The <sup>1</sup>H NMR spectrum of the compound [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] confirmed the formation of the complex. The two signals appearing at 2.50 and 3.40 ppm are attributed to the methylene groups. Also, multiple independent signals are observed around 8.12-7.80 ppm related to aromatic protons of the phenyl group.

## 3.6. Mass spectra

The mass spectra were collected at 70 V cone voltage for all complexes (**1**, **2** and **3**) to reduce the dissociation of ligand. Chemical elements have different isotopes that occurred naturally. Due to isotopic abundance, for some fragments the number of peaks was higher than the calculated. The voltage and the nature of the substitution groups relatively can affect the peak intensity (Keypour et al., 2014). Some water molecules suggested being involved with complexes structures to justify mass spectra results as it is very often in such syntheses to obtain chemical structures with water molecules such as [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].7H<sub>2</sub>O, [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].6H<sub>2</sub>O and [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>].3H<sub>2</sub>O due to wet solvents that used in syntheses such as EtOH and MeOH.

### 3.6.1 [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>]

In the mass spectrum of the complex [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].7H<sub>2</sub>O, the molecular ion peak (M<sup>+</sup>) was observed at m/z 599.60. The spectrum shows

two other main peaks (577.60 and 551.60) (**Figure 6**), corresponding to the ions of [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].5H<sub>2</sub>O and [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].4H<sub>2</sub>O respectively. Later [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] complex losing NH<sub>4</sub>Cl and NH<sub>3</sub> leaving ions at m/z (calc. 401.96, found 400.20, and calc. 373.92, found 381.30) respectively.

### 3.6.2 [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>]

In the mass spectrum of [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] complex, the peak at 594.60 m/z is due to the molecular ion [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].6H<sub>2</sub>O<sup>+</sup>. The peaks at 551.60 m/z is related to [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>].4H<sub>2</sub>O fragment. The intensity of these peaks is clear evidence of the stability of these fragments. The mass fragmentation pattern of the Cu(II) complex is depicted in **Figure 7**. The spectrum of [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] complex shows a peak at m/z (calc. 448.91, found 451.50), indicating the loss of NH<sub>3</sub>, 4H<sub>2</sub>O, and Cl. The ion at m/z 451.50 loses CH<sub>3</sub>CH<sub>2</sub>NH<sub>4</sub>Cl, leaving an ion at m/z (calc. 313.97, found 313.30), which further loses two CH<sub>3</sub>CH<sub>3</sub> molecules to leave an ion at m/z (calc. 231.91, found 236.30). Two intense peaks observed at low mass (57.20 and 83.10 m/z) are due to trace of unreacted starting material such as CuCl<sub>2</sub> fragments.

### 3.6.3 [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>]

The mass spectrum of [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>].3H<sub>2</sub>O complex shows a molecular ion peak at m/z 591.60. Two main peaks, at 577.60 and 551.60 m/z (**Figure 8**) attributed to [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>].2H<sub>2</sub>O and [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>].H<sub>2</sub>O fragments and their intensity prove the fragments stability. The molecular ion of [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>] complex loses NH<sub>4</sub>Cl and Cl leaving an ion at m/z (calc. 460.02, found 466.50), which by its turn, loses NH<sub>3</sub>, Cl, and HCl giving an ion at m/z (calc. 386.08, found 381.50).

## 3.7. Biological activity

The prepared metal complexes (**1**, **2**, **3**) and L<sub>1</sub> ligand were *in vitro* screened for their antibacterial activity by the disc diffusion and microdilution methods, according to the European Committee on Antimicrobial Susceptibility Testing and Clinical and Laboratory Standards Institute guidelines (Ansari et al., 2011). The biological activity of these compounds was tested against a set of human pathogenic gram-negative and gram-positive bacteria, respectively, *Enterobacter cloacae* G-, *Citrobacter* G-, *Pseudomonas* G-, *Klebsiella* G-, *Staphylococcus* G+, and *Streptococcus* G+. The minimum effective concentration of compounds was also

investigated and compared with Amoxicillin and Azithromycin as reference drugs (10 mg mL<sup>-1</sup>) (**Table 1**). At low concentration, approximately, all complexes displayed destruction activity to all tested bacteria. **Table 1** shows the inhibition zone of Gr- bacteria by Schiff base metal complexes and L<sub>1</sub> ligand. Metal complex (**2**) inhibited *Enterobacter cloacae* G- growth significantly in comparison with the ligand L<sub>1</sub> using the same strain. This clearly indicates that the metal complex (**2**) has a destructive effect on bacteria activity. Among the prepared compounds, complexes **1** and **3** were found to be less active than L<sub>1</sub> against *Enterobacter cloacae* G- with MIC (minimum inhibitor concentration) expressed in terms of generated inhibition zones (13 and 14 mm) values, respectively, but showed higher inhibition than the reference drug (**Figure 9**). Moreover, compounds (**1-3**) and L<sub>1</sub> are more effective against *Enterobacter cloacae* G- than the reference drugs.

Inhibition percentages for the compounds (**1-3**) and L<sub>1</sub> presented in **Figure 10** exhibited an excellent effect (inhibition zones of 4, 28, 45, 48 mm) against *Citrobacter* G- compared to other isolated strains and the reference drugs. As seen in **Figure 10** and **Table 1**, inhibition activity increases significantly for the L<sub>1</sub> ligand after coordination with metal ions (Gündüzalp et al., 2016; Parlakgümüş et al., 2016).

Compounds (**1-3**) and L<sub>1</sub> ligand were shown to have promising antimicrobial activity against *Pseudomonas* G-. **Figure 11** and **Table 1** clearly showed a significant increase in the inhibition activity of L<sub>1</sub> Schiff base ligand after coordination to metal ions (Ansari et al., 2011). The anti-*Pseudomonas* G- inhibition activity of L<sub>1</sub> was (0 mm) and became (25, 30, 15 mm) for compounds **1**, **2** and **3**, respectively. Also, in comparison with reference drugs, this experiment clearly proves the significant distraction action of the metal complexes antibiotic *versus* organic antibiotic (Gündüzalp et al., 2012).

As expected *Klebsiella* G- showed a strong resistance to complexes **1-3** and L<sub>1</sub> (**Figure 12**) as it is well-known its resistance to a wide array of antibiotics. Complexes **1-3** and L<sub>1</sub> in addition to the reference drugs did not show any antibacterial activity against *Klebsiella* G- and the inhibition zones were 0 mm for all tested compounds (€Ozbek et al., 2013).

All four tested compounds showed significant activity against the selected gram-positive pathogens (*Staphylococcus* G+, and *Streptococcus* G+), the L<sub>1</sub> ligand activity against

*Staphylococcus* G+ increases significantly after coordinating to metal ions. Complex **3** showed maximum inhibiting activity against the organisms here study. Complex **2** did not show any antibacterial activity against *Streptococcus* G+, which could be related to the experimental condition. The results (**Table 2** and **Figures 13** and **14**) show that the compounds affect more the *Staphylococcus* G+ and less the *Streptococcus* G+ (Muche et al., 2017).

#### 4. CONCLUSIONS:

The prepared complexes showed promising results in the conducted biological tests. Highly air and thermal stable Schiff base metal complexes [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>], [(CuCl<sub>2</sub>)<sub>2</sub>L<sub>1</sub>] and [(NiCl<sub>2</sub>)<sub>2</sub>L<sub>2</sub>] with a melting point ranged between (237-248 °C) were synthesized in one step reaction pot by reacting tetradentate ligands (Eqn. 1) with different metal chlorides. Complexes (**1**, **2**, **3**) showed high chemical stability in DMSO for at least 72 h. The compounds were chemically characterized using a set of analytical techniques such as IR, <sup>1</sup>HNMR spectroscopy, and MS spectrometry. The biological properties of the complexes were determined according to the broth microdilution technique by employing a range of gram-negative and positive bacteria strains such as *Enterobacter cloacae* G-, *Citrobacter* G-, *Pseudomonas* G-, *Klebsiella* G-, *Staphylococcus* G+, and *Streptococcus* G+. It was established out that complexes are very effective inhibition activity ranged between (13-50 mm) against gram negative and gram positive pathogens. The comparison results revealed better antibacterial activity of the synthesized complexes than reference drugs (Amoxicillin and Azithromycin). These results encourage further studies of these species to identify the activity of the compound toward new pathogens.

**RESUMO**

Estudos na área de ensino de química descobriram que as estratégias de aprendizagem baseada em problemas (PBL) melhoram efetivamente a compreensão conceitual dos alunos. No entanto, há informações muito limitadas sobre a eficácia do PBL se ele for aplicado com representação múltipla (RM) para estudantes com diferentes preferências de aprendizado. Este estudo teve como objetivo provar os efeitos das estratégias de aprendizagem baseada em problemas (PBL) usando múltiplas representações (RM) e os estilos de aprendizagem dos alunos no entendimento conceitual em química. Havia duas aulas intactas no Departamento de Engenharia Mecânica do Politécnico do Estado de Bali que foram designadas para serem grupo experimental ( $n = 59$ ) e grupo controle ( $n = 58$ ). O Índice de Estilo de Aprendizagem (ILS) de Felder-Soloman foi aplicado para diferenciar as preferências de aprendizagem dos alunos, enquanto seu entendimento conceitual em química foi avaliado usando um teste após 6 semanas de tratamento. A análise de covariância (ANCOVA) mostra que a compreensão conceitual dos alunos ensinados usando estratégias de PBL com RM foi significativamente melhor do que aqueles ensinados usando apenas estratégias de PBL. Além disso, com base na variação dos estilos de aprendizagem, os alunos com estilo visual tiveram uma melhor compreensão conceitual do que aqueles com estilo verbal, mas a diferença não foi estatisticamente significativa. A ausência de efeito de interação entre estratégias de PBL com RM e estilo de aprendizagem na compreensão conceitual dos alunos sugere que o suporte de múltiplas representações nas estratégias de PBL pode efetivamente aprimorar a compreensão dos conceitos dos alunos em química, independentemente de seu estilo de aprendizagem.

**Palavras-chave:** representações múltiplas, aprendizagem baseada em problemas, estilos de aprendizagem, química

**ABSTRACT**

Studies in the area of chemistry teaching discovered that problem-based learning strategies (PBL) effectively improve students' conceptual understanding. However, there is minimal information about the effectiveness of PBL if it is applied with multiple representations (MR) for the students with different learning preferences. This study aimed to prove the effects of problem-based learning strategies (PBL) using multiple representations (MR) and students' learning styles on the conceptual understanding in chemistry. There were two whole classes in the Mechanical Engineering Department of Bali State Polytechnic that were assigned to be the experimental group ( $n=59$ ) and control group ( $n=58$ ). Felder-Soloman's Index of Learning Style (ILS) was applied to differentiate the students' learning preferences, while their conceptual understanding in chemistry was assessed using a test after 6 weeks of treatment. The analysis of covariance (ANCOVA) shows that the conceptual understanding of students taught using PBL strategies with MR was significantly better than those taught using PBL strategies only. Besides, based on the variation of learning styles, students with a visual style had a better conceptual understanding than those with verbal style, but the difference was not statistically significant. The absence of interaction effect between PBL strategies with MR and learning style on students' conceptual understanding suggests that the support of multiple representations in PBL strategies can effectively

enhance students' understanding of concepts in chemistry regardless of their learning style.

**Keywords:** *multiple representations, problem-based learning, learning styles, chemistry*

## 1. INTRODUCTION:

Improving the quality of instruction is challenging for education institutions in Indonesia, especially vocational education, as a polytechnic, to generate human resources who can compete in a global age. Education at the Polytechnic prioritizes the application of practical aspects rather than theory. Chemistry, as one of the courses of theory in the field of mechanical engineering at the Polytechnic, faces challenges in the learning process that was implemented during this time because students who attend the program have a non-linear science field with chemistry. According to the majority of students, chemistry is difficult to understand, even though the application of chemical concepts in the field of mechanical engineering can support its competence in solving problems in the field such as corrosion control, the development of green energy, metal coating and waste treatment. Difficulties in understanding concepts in chemistry are related to student characteristics. Learning about chemistry needs a lot of conceptual understandings for students to be able to solve problems related to the thoughts which they learned. Conceptual understanding is a crucial aspect of instructional because the critical purpose of teaching is to help the student understand concepts in the subject matter as well as to explore a topic deeply (Santrock, 2011).

Complex challenges to understand concepts and to connect between concepts in finding new knowledge, require instructional strategies that are simple and useful for students. Chemistry is a complicated subject but has relevance and an essential role in engineering studies. Solutions to overcome these challenges through innovation in chemical learning include instructional strategies and media with new technologies that are contextual with the subject matter (Llorens-Molina & Pinto, 2014).

An instructional strategy is one or more procedures that are received by the individual to facilitate the learning task. Problem-based learning (PBL) is an instructional strategy that represents a significant change in the educational paradigm and recognized as a more proper way of education in the 21st century (Gwee, 2009). The characteristics of PBL are including, empowering learners to do research, encouraging them to integrate theory and practice and to apply

knowledge and skill to resolve the real problem (Savery, 2006). PBL has two fundamental postulates. First, learning by problem-solving is more useful for the learner to create knowledge that can use in the future. Second, the learner would have problem-solving skills instead of memorizing (Barrows & Tamblyn, 1980). The implementation of the PBL strategy of instructional has a contribution to the development of learner's creative thinking skills. Enhancing individual's creative thinking is one of the high-level thinking skills. This is a crucial point because nowadays, there is a lot of individual needs to think creatively (Ersoy & Başer, 2014).

An important aspect of PBL strategy starts with the problem as the focus of the learning process that can encourage students to find information needed for problem-solving and to learn to integrate and organize data so that later, students can maintain and apply the knowledge while solving problems. PBL strategies involve the use of individual intelligence, human groups, and the environment to solve urgent, relevant, and contextual problems. In PBL strategies, understanding comes from interacting with problem scenarios and the learning environment, helping students to build their knowledge and thinking skills, involvement with problems, and the process of problem inquiry as well as social, collaborative processes (Tan, 2003). PBL strategies are complex real-world problems that motivate students to identify and research concepts and principles (Duch, Groh, & Allen, 2001). PBL is a good learning strategy to improve student academic achievement, to develop social skills, to be active in group discussions, and to become independent learners (Argaw *et al.*, 2017). The PBL strategy has advantages compared to other learning strategies. PBL is very useful for increasing student knowledge, learning the results, and having a positive effect on their learning achievement (Maysaraa, 2016; Wilder, 2014; Yew & Goh, 2016).

Studies in the area of chemistry teaching discovered that PBL effectively improves students' conceptual understanding (Ayyildiz, & Tarhan, 2017; Bilgin, Şenocak, & Sözbilir, 2009; Günter & Alpat, 2016; Overton & Randles, 2015; Taşoğlu & Bakaç, 2014; Valdez & Bungihan, 2019; Yaayin, 2018). PBL offers chances for students to learn in a team, improve presentation skills, learn negotiating skills, and improve research skills as

well as other skills (Mossuto, 2009). PBL enhances group activities, as well as improves students' soft and hard skills (Nurtanto *et al.*, 2018). In the area of vocational education, especially in technical engineering, PBL as an instructional strategy was proven to be effective in accelerating the student's high-level skills in communication and the ability to apply new knowledge and skills corresponding to vocational education (Sada *et al.*, 2015). Besides, PBL strategies would also increase professional awareness and communication skills (Jabarullah & Hussain, 2019). Problem scenario designed in PBL presenting real-world problems which are relevant to their professional field, which will encourage them to involve in the instructional topic and develop their understanding level to achieve the instructional objective.

Achieving the expected learning objectives is not only determined by the instructional strategies applied but also requires the delivery strategies in the representation of a concept. Students need support to integrate new ideas from a visualization with their prior knowledge (Garcia & Elene, 2014). Representation is also something that represents, visualize, and symbolize object and process (Goldin, 2002). Representational competence is a part of conceptual understandings that include the ability to explain a phenomenon and integrate new knowledge gained from various or multiple representations. Representational competence is a part of conceptual understandings that include the ability to explain a phenomenon and integrate new knowledge from multiple representations.

There are three functions of multiple representations. First, to give a presentation contains complementary information or to help to complete the cognitive process. Second, to limit mistake possibilities in interpreting other representations. And third, to help learners building deep situation concepts (Ainsworth, 1999). Multiple representations can encourage the learner to construct ideas genuinely and connect representations. The representations of chemical concepts consist of macroscopic level, sub-microscopic level, and symbolic (Johnstone, 1993). The macroscopic level refers to representation obtained through real experience, and that can see directly. The sub-microscopic level describes an abstract of the chemical phenomenon and explains the structure and process in the particle levels, and that cannot see directly. The symbolic level is a representation to identify entities using qualitative and quantitative symbolic language, such as chemical formulas,

equations, stoichiometry. A representation is concluded as a way to express phenomena, objects, abstract concepts, ideas, processes, and mechanisms. Students can understand the concept of chemistry intact if they can connect representations at the macroscopic, sub-microscopic, and symbolic levels (Gilbert & Treagust, 2009). The success of understanding a concept in learning is not only influenced by the learning strategies and delivery that is applied, but is also influenced by students' learning styles in processing information.

Learning style refers to a group of psychological traits that determine how individuals perceive, interact, and respond emotionally to the learning environment (Heinich *et al.*, 2002). It includes not only the cognitive aspect of learners but also the affective aspect, which makes it a reflection of learners' personality (Litzinger, 2007). Learning styles are closely related to the information design, format, and delivery method used in facilitating students in learning, understanding concepts, and problem-solving abilities. Therefore, it can be differentiated based on learners' sensory preferences. There are four dimensions of learning style, including; perception (sensing-intuitive), input (visual-verbal), processing (active-reflective, and understanding (sequential-global) (Felder & Silverman, 1988). This model is often used to study and identify the learning styles of students in science and engineering education.

Many strategies can be adapted to stimulate students to respond to learning materials based on their learning style preferences. Studies in the area of learning style found that it had a significant effect on chemistry learning achievement and student success and have distribution to improving the understanding concept (Murat, 2013; Olić & Adamov, 2018). Learning styles contribute positively to the improvement in efficiency, the effectiveness of the learning process, and the academic performance of students (Magulod, 2019; Sidiropoulou & Mavroidis, 2019). The learning style emphasized in this study is the verbal-visual dimension because it relates to multiple representations.

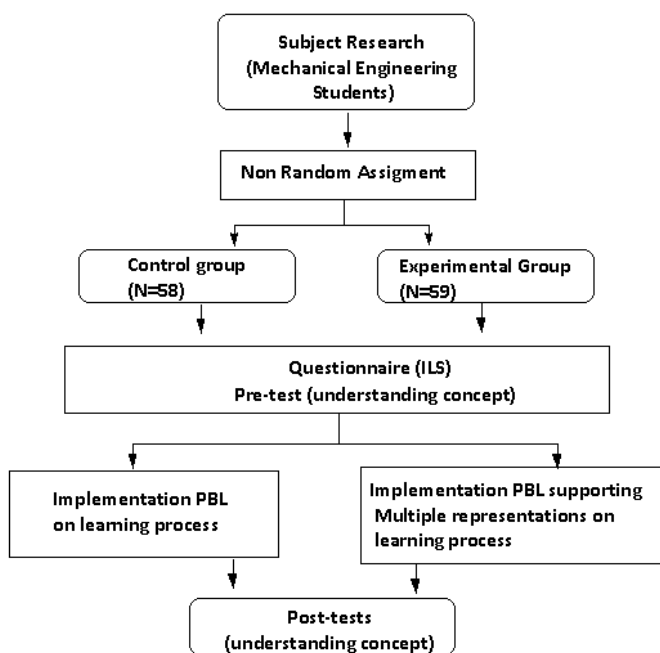

Based on the reviews, as mentioned above on PBL strategies, multiple representations, and learning styles, this study aims to investigate the effect of PBL strategies with the support of multiple representations and learning styles on students' conceptual understanding of chemistry.

## 2. MATERIALS AND METHODS:

### 2.1. Research Design

This study used a quasi-experimental research design to examine whether the effect of PBL strategies using multiple representations on students' conceptual understanding depends on their learning style. There were two whole classes in the Mechanical Engineering Department of Bali State Polytechnic that were assigned to be the experimental group ( $n=59$ ) and control group ( $n=58$ ). It was confirmed that all participants agreed to participate in this study. Based on the result of the pre-test, the control group gained a mean total score = 34.913, while the experimental group gained = 34.966. This result indicates that both classes had the same level of conceptual understanding and were eligible for the following experimental procedures. The experimental group was experiencing PBL strategies with multiple representations (MR), while the control group was implemented PBL strategies. Those treatment procedures were last for 6 meetings. Learning style compared in this study emphasizes on two dimensions, namely verbal-visual, acting as a moderator variable. The overall research subjects were male, with the majority were graduated from vocational high schools.

The outline of the research design is illustrated in Figure 1.

**Figure 1.** Outline of Research Design

### 2.2. Instruments

The instruments used to collect data were tests and questionnaires. The test consists of 25 multiple choice questions related to electrochemical concepts, such as oxidation-reduction reactions in electrochemical cells, the direction of electron movement in cells, cathode-anodes, reduction or oxidation reactions, energy changes, salt bridges, charge and recharge processes on batteries, mechanism of action fuel cell, corrosion process, and metal coating process (Appendix 1). This test has been regularly used to evaluate the students' conceptual understanding of chemistry in the Mechanical Engineering Department.

The questionnaire, consisting of 11 questions, was used to determine the subject's learning style, especially on the verbal-visual dimension. The questionnaire was adopted from the Index of Learning Style (ILS) developed by Felder and Solomon (North Carolina State University, Felder, & Solomon, 2020) (Appendix 2). The internal consistency reliability of the 11 verbal-visual dimension questions of ILS is .76 indicated by Cronbach Alpha coefficient (Litzinger *et al.*, 2007).

### 2.3. Implementation of PBL Strategy

The topic of the chemistry subject given in this research is about electrochemistry. Learning outcomes based on the syllabus of applied chemistry course are students understanding and explaining oxidation-reduction reactions, potential standard cells, Voltaic cells, batteries, corrosion, fuel cells, electrolytic cells, electroplating. They can explain the difference between voltaic cells and electrolytic cells. Worksheets are given to students both in the control group, and the experimental group complimented with problem scenarios based on facts happened in the field, in the daily life and real problem, which related to the given subject matter. The real-life context of an applied aspect of chemistry in the learning scenario helps the students to identify the problem. The problem scenarios given to all groups are the same. The topics were selected from the news that occurs in the field and related to the electrochemical concept, as presented in Table 1.

Implementation of the PBL strategy in research adopted a set of rules (syntax) (Arends, 2012, p. 414). During the PBL implementation process, the instructor acts as a facilitator and motivator, who help the students to develop critical thinking skills, independent learning and build new

knowledge as an effort to find solutions to problems. The detailed implementation of PBL Strategy in both the control group & experimental group is provided in Table 2.

The null hypotheses are formulated as follows:

1. There is no difference in chemistry conceptual understandings between the students in the control group and the experimental group
2. There is no difference in chemistry conceptual understandings between the students verbal and visual learning style
3. There is no interaction effect between PBL strategies and learning styles on chemistry conceptual understanding.

### 3. RESULTS AND DISCUSSION:

#### 3.1 The Result of Learning Style Questionnaire

The results of the distribution of learning style questionnaires to all research subjects showed that most of the research subjects had visual learning styles, as shown in Table 3.

**Table 3.** Students' based on Learning Style

| Groups       | Learning Style |        | Total |
|--------------|----------------|--------|-------|
|              | Verbal         | Visual |       |
| Control      | 13             | 45     | 58    |
| Experimental | 16             | 43     | 59    |

#### 3.2. The Result of Control Group Activity

Strategy activities in the control group, based on the four givens, all information collected to find solutions to the problems identified and also complete the tasks contained in the worksheet. Some Problems were identified by each group, such as reactions that occur in batteries, reduction-oxidation reactions, differences between primary and secondary batteries, the difference between dry batteries and wet batteries, reactions in fuel cells, corrosion occurs in metals, electrolysis cells, and electroplating with chrome metal.

#### 3.3. The Result of Experimental Group Activity

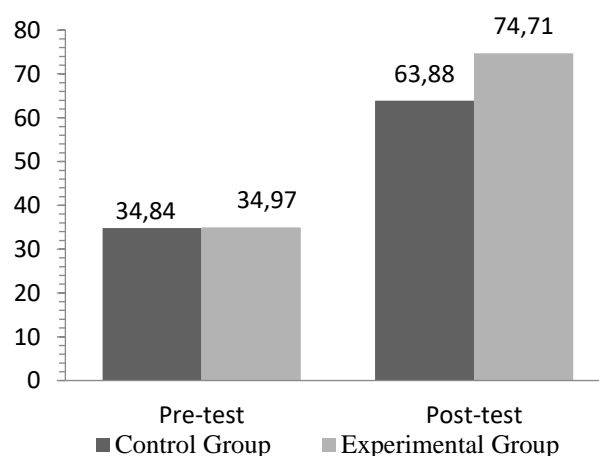

In the experimental group, the activities carried out were almost the same as the control class. Information is collected to find solutions to problems that have been identified, including macroscopic, submicroscopic, and symbolic

aspects, for example, about electroplating mechanisms. Answering the question, the information collected is related to the electrode, the direction of the electron's movement in the coating process, the process of oxidation, and reduction. An Understanding process in chemical reaction requires visualization technology that can integrate into three levels of representation so that it can be presenting simultaneously. Therefore, in the experimental group to solve problems and answer tasks requires electrochemical multimedia modules that are supported by a dynamic visualization of abstract concepts.

#### 3.4. The Effect of PBL Strategies with Multiple Representation and Learning Style on Students' Conceptual Understanding

Table 4 shows the pre-test result and also the post-test results from both of the groups after six meeting treatments. The post-test mean score of the control group is 60.759, and the experimental group is 74.711. In Table 5, the inferential statistical analysis using ANCOVA shows that the significance value of the applied PBL strategies on conceptual understanding in the post-test is 0.000 ( $p < 0.05$ ). It means that the first null hypothesis is rejected. There were significant differences between the learning strategies (PBL) applied toward students' conceptual understanding.

The level of understanding of students' concepts measured by the score gained from the pre-test and post-test. The average scores of pre-test and post-test on electrochemical conceptual knowledge can be seen in Figure 2.

**Figure 2.** The Average Scores of Pre-test and Post-test on Electrochemical Conceptual Understanding

As shown in Table 5, the significance value of the learning style variables on conceptual understanding in the post-test is 0.962 ( $p > 0.05$ ). It means that there is not enough evidence to reject the second null hypothesis. The differences of conceptual understanding between students with verbal and visual learning styles were not significant.

Figure 3 shows the gain comparison of the post-test results on electrochemical conceptual understanding based on instructional strategies applied and students' learning styles aspects. It shows that the discrepancy was only identified between the students taught using PBL and PBL plus multiple representation strategies. There is no meaningful score difference found between students with verbal or visual learning preferences.

**Figure 3.** The Post-test Results on Electrochemical Conceptual Understanding based on Instructional Strategies and Learning Styles Aspects

To answer the third hypothesis, referring to Table 5, it can be explained that there was no interaction between PBL strategies with MR and learning styles toward conceptual understandings. In other words, support of Multiple Representations in Problem-Based Learning strategies can effectively enhance students' understanding of concepts in chemistry regardless of their learning style.

The implementation of PBL strategies with MR in learning has a positive effect on students' understanding of concepts in chemistry for mechanical engineering students. Presenting concrete facts about the application of chemical concepts in the field of mechanical engineering through the design of the scenarios provided is an attraction for students to learn to understand the concepts being studied. The plot designed is

adapted to real situations that occur in everyday life and has to do with the concept of electrochemical material that can apply to the field of mechanical engineering. The instructor acts as a facilitator, motivator, and directs students who are divided into groups to make a hypothesis of the problem found by the scenario presented. Students in control and experimental groups seemed eager to follow the stages of the PBL implementation process. Fostering the ability to work together between individuals in a group is also an advantage of PBL.

The concept of electrochemistry is a material that is very applicable in the field of mechanical engineering. Having a good understanding of the concepts of chemistry, especially electrochemistry, will be able to support the competencies of students in developing their resources. The experimental group that was given the PBL strategy with the support of multiple representations gave better results to the improvement of understanding of the concept compared to without multiple representations. That is because Chemistry with scientific characters dominated by abstract concepts is very important to be supported by multiple representations in the chemistry learning process to minimize the difficulty of students understanding concepts.

Several research results have proven that multiple representations in chemistry learning have an important role in improving students' understanding of concepts and the quality of chemistry learning (Emine & Yakmaci-Guzel, 2013; Sunyono & Meristin, 2018). They learn science concepts; students need to understand various representations of scientific concepts, be able to translate between different representations, and demonstrate the capacity to construct representations in any form for specific purposes (Cheng & Gilbert, 2009). Understanding the concept of chemistry intact is if it can connect representations at the macroscopic, sub-microscopic, and symbolic levels. The combination of levels of representation (macroscopic, symbolic, and submicroscopic) can develop a deeper and more structured understanding of concepts (Baptista, *et al.*, 2019).

Some applications of chemical concepts in the field of mechanical engineering can significantly support the competence of an engineer in developing his scientific resources. Engineering students are also expected to have an excellent conceptual understanding of basic science, including chemistry. Similar results also to find, the application of PBL in learning basic

science for engineering students can improve conceptual understanding and an effective teaching pedagogy to enhance professional skills for engineering students (Beagon & NíFhloinn, 2018; Sahin, 2010). Multiple representations are essential in the study of chemistry, because learning chemical concepts, not only presented phenomena that can see with the naked eye but also abstract phenomena. For example, the characteristics of metal undergoing corrosion can be seen directly from the change in its color, but the process of the change cannot be seen immediately (sub-microscopic). Sub microscopic representation can use with the help of visualization technology. The experimental group in studying electrochemical concepts with multiple representations has an impact on being able to understand the direction of electron movement in galvanic cells, corrosion processes, batteries, electrolytic cells, and electroplating.

In connection with the findings in answering the second hypothesis, no effect was found between learning styles on conceptual understanding. Based on the results of the questionnaire distribution of learning styles, it is seen that visual learning styles are more dominant than verbal. Still, these results do not contribute to increasing conceptual understanding. This result is supported by several findings from the results of the study (Garner-O'Neale & Harrison, 2013; Kidanemariam, Atagana, & Engida, 2014) concluded that learning styles do not contribute to improving the academic achievement of chemistry students, fundamental understanding concepts and learning outcomes. The same results, that interaction between learning style and academic achievement was not significant and did not affect academic achievement (Sahin, 2010). Learning styles relate to each individual's way of receiving new information. In the context of this study, there are indications that the strategies implemented can accommodate how students obtain new information in improving the understanding of concepts. Although learning styles do not have a direct effect, learning styles possessed by students in learning are essential to consider.

#### 4. CONCLUSIONS:

Based on the findings in this study, it can be concluded that the PBL strategy could enhance the students' understanding of the concept in chemistry. However, PBL strategies that apply with multiple representations show significantly better results compared to those without multiple representations. Besides, students' learning style

does not directly influence the improvement of students' understanding of concepts. So that, the support of Multiple Representations in Project-Based Learning strategies can effectively enhance students' understanding of concepts in chemistry regardless of their learning style.

It is envisaged that this study might contribute to the research in instructional strategies, especially in the area of chemistry teaching, by providing two leading suggestions. First, the chemistry teacher may apply the PBL strategies with MR to improve students' conceptual understanding without worrying about students' input preferences. Second, other researchers should corroborate this study in other contexts and might ensure the effectiveness of PBL with MR by considering the different dimensions of students' learning preferences

b. R Squared = .333 (Adjusted R Squared = .321)

## APPENDIX 1.

### MULTIPLE CHOICE TESTS

#### UNDERSTANDING OF CONCEPT OF ELECTROCHEMISTRY

Directions:

1. Read each question carefully and circle one the best answer.
2. Allocation of time available to take the test is 60 minutes

Take a look at the Galvanic cell series below. The picture is related to several questions.

1. When the Galvanic cell is working..
  - a. Chemical energy from reactions in cells converted into electrical energy
  - b. Chemical energy from reactions in cells converted into heat energy
  - c. Electrical energy from reactions in cells converted into chemical energy
  - d. The electrical energy from reactions in cells converted to heat energy
2. Galvanic cells equipped with electrodes. The electrodes are ...
  - a. Semiconductor dipped in an electrolyte solution
  - b. The conductor dipped in an electrolyte solution
  - c. Semiconductor dipped in an acidic or basic solution
  - d. A conductor dipped in an acid or base solution
3. When Galvanic cells work, redox reactions occur ..
  - a. In the electrolyte solution
  - b. On the inside of the electrode
  - c. On the surface of the electrode
  - d. In the electrolyte solution and inside the electrode
4. Read the following statements:
  - i. The anode is a negative pole (-) and where the oxidation reaction takes place
  - ii. The anode is a positive pole (+) and where the oxidation reaction takes place
  - iii. The cathode is the negative pole (-) and the place of the reduction reaction
  - iv. The cathode is the positive pole (+) and where the reduction reaction takes placeThe correct statement is:
  - a. i and iii
  - b. i and iv
  - c. ii and iii

- d. iii
5. Galvanic cells consist of two half cells. Half the cell is:
    - a. Where oxidation and reduction reactions occur in one place
    - b. Where oxidation or reduction reactions take place separately and not at the same time
    - c. Where oxidation or reduction reactions take place separately and at the same time.
    - d. The oxidation or reduction reactions take place separately to form positive and negative ions which dissolve in the electrolyte solution
  6. When the Galvanic cell works:
    - a. The cation from the salt bridge moves to the cathode, while the anion moves to the anode
    - b. The anion from the salt bridge moves to the cathode, while the anion moves to the anode
    - c. Both cations and anions can move to the cathode or anode
    - d. The cations and anions of the salt bridge remain in the salt bridge
  7. The movement of electrons when Galvanic cells work from..
    - a. Anode to the cathode through the salt bridge
    - b. Cathode to the anode through the salt bridge
    - c. The anode to the cathode through the conducting wire.
    - d. Cathode to the anode through the conducting wire
  8. When the Galvanic cell is working..
    - a. Cu reduced to  $\text{Cu}^{2+}$ ; Zn oxidized to  $\text{Zn}^{2+}$
    - b.  $\text{Cu}^{2+}$  oxidized to Cu;  $\text{Zn}^{2+}$  reduced to Zn
    - c.  $\text{Zn}^{2+}$  reduced to Zn; Cu oxidized to  $\text{Cu}^{2+}$
    - d.  $\text{Cu}^{2+}$  reduced to Cu; Zn reduced to  $\text{Zn}^{2+}$
  9. Dry cell batteries are so-called because..
    - a. The used electrolyte is completely dry
    - b. The used electrolyte is a moist paste
    - c. It is using dry electrodes
    - d. None of the above
  10. Which of the following statement is correct..
    - a. The capacity of a cell measured in volts
    - b. Primary cells convert electrical energy into chemical energy
    - c. Galvanizing of ferrous metals can prevent corrosion
    - d. Positive electrodes are called cathodes
  11. Which of the following batteries commonly used at electric power stations?
    - a. Zink-Carbon Battery
    - b. Nickel-Cadmium Battery
    - c. Lead-acid battery
    - d. Lithium battery
  12. Fuel cells used to convert chemical energy into..
    - a. Electricity energy
    - b. Mechanical energy
    - c. Electricity energy
    - d. Potential energy
  13. Choose the wrong statement from the following options..
    - a. Fuel cell emission levels are far below the permitted limit
    - b. Fuel cells have a high level of noise
    - c. Fuel cells have high-efficiency

- d. Fuel cells are modular
14. The change that happened during the process of charging the battery is ..
- Chemical energy becomes heat energy
  - Electrical energy becomes chemical energy
  - Chemical energy becomes electrical energy
  - Chemical energy becomes chemical energy

The picture is related to several questions below

15. What is the energy conversion that occurred in the cell above ....
- Chemical energy becomes heat energy
  - Heat energy becomes electrical energy
  - Electrical energy becomes chemical energy
  - Electrical energy becomes heat energy
16. The occurrence of the electroplating process is marked by..
- Electrons move from the anode to the cathode
  - Electrons move from the cathode to the anode
  - Coating occurs at the anode
  - Anode mass increases
17. In the cell above, what acts as a cathode ..
- Ag
  - Pt
  - Spoon
  - Cu
18. During the reaction in the electrolytic cell ...
- Oxidation occurs at the anode
  - Oxidation occurs at the cathode
  - Reduction occurs at the anode
  - Reduction occurs in the conducting wire
19. Electroplating is an example of the application of electrochemical cells from .....
- Electrolytic cell
  - Galvanic Cells
  - Voltaic Cell
  - Fuel cell
20. The functions of electroplating include, except..
- Aesthetics
  - Harden metal surfaces
  - Protect metal from corrosion
  - Increase corrosion rate

21. In electrolytic cells, chemical reactions take place ....
  - a. Spontaneously
  - b. Not spontaneously
  - c. Back and forth
  - d. Out of circuit
22. The difference between galvanic cells and electrolytic cells is
  - a. Both occur spontaneously
  - b. In a galvanic cell, electrical energy is converted into chemical energy; in electrolytic cells, chemical energy is transformed into electrical energy
  - c. In electrolytic cells, electrical energy is converted into chemical energy on galvanic cells, and chemical energy is transformed into electricity
  - d. Galvanic cells require an external current
23. Factors affecting the rate of corrosion in metals include, except..
  - a. Temperature
  - b. pH
  - c. Concentration
  - d. Bond
24. The battery that is classified as a secondary cell is ...
  - a. Silver oxide battery
  - b. Mercury oxide batteries
  - c. Lead-acid battery
  - d. Zinc-carbon battery
25. The change happened during the process of discharging the battery is...
  - a. Chemical energy becomes heat energy
  - b. Electrical energy becomes chemical energy
  - c. Chemical energy becomes electrical energy
  - d. Chemical energy becomes chemical energy

## APPENDIX 2.

### Visual/Verbal Learning Style Questionnaire

This questionnaire is designed to find out what your learning preferences are; (Verbal/Visual).

Direction:

1. This questionnaire is consisted of 11 questions and should be done in 15 minutes.
  2. Read each of the question carefully and please put a cross (X) on 'a' or 'b' to indicate your answer.
- 
1. When I think about what I did yesterday, I am most likely to get
    - a. picture.
    - b. words.
  2. I prefer to get new information in
    - a. pictures, diagrams, graphs, or maps.
    - b. written directions or verbal information.
  3. In a book with lots of pictures and charts, I am likely to

- a. look over the pictures and charts carefully.
  - b. focus on the written text.
4. I like teachers
- a. who put a lot of diagrams on the board.
  - b. who spend a lot of time explaining.
5. I remember best
- a. what I see.
  - b. what I hear.
6. When I get directions to a new place, I prefer
- a. a map.
  - b. written instructions.
7. When I see a diagram or sketch in class, I am most likely to remember
- a. the picture.
  - b. what the instructor said about it.
8. When someone is showing me data, I prefer
- a. charts or graphs.
  - b. text summarizing the results.
9. When I meet people at a party, I am more likely to remember
- a. what they looked like.
  - b. what they said about themselves
10. For entertainment, I would rather
- a. watch television.
  - b. read a book.
11. I tend to picture places I have been
- a. easily and fairly accurately.
  - b. with difficulty and without much detail.

**RESUMO**

O ponto principal da alfabetização ambiental é aumentar a preocupação individual com a crise ambiental em ações concretas ou movimentos de cuidado ambiental. Esta pesquisa visa capacitar o conhecimento de professores de biologia da preservação sobre o meio ambiente e seus problemas em contextos ecológicos e sociais e habilidades cognitivas para investigar e planejar soluções para os problemas. O método de pesquisa quantitativa com o design de um grupo pré-teste e pós-teste foi empregado para testar o aumento do conhecimento ambiental após o aprendizado. O efeito estimulante são as habilidades cognitivas para superar problemas ambientais. Os participantes da pesquisa consistiram em 29 professores de biologia em treinamento cursando ciências ambientais no primeiro semestre. O conhecimento ambiental foi medido por meio de um teste de ensaio, enquanto a mensuração das habilidades cognitivas foi realizada por meio de uma rubrica com escala de classificação baseada nos resultados de investigações de problemas ambientais em campo. Verificou-se que o modelo de aprendizagem de etnossocioecologia em laboratório poderia melhorar significativamente o conhecimento ambiental. Além disso, o conhecimento ambiental está positivamente correlacionado com as habilidades cognitivas. Em geral, as habilidades cognitivas aumentam com maior conhecimento ambiental.

**Palavras-chave:** *habilidades cognitivas, conhecimento ambiental, alfabetização ambiental, etnossocioecologia, laboratório de investigação.*

**ABSTRACT**

The main point of environmental literacy is to increase individual concern towards the ecological crisis in concrete action or environmental care movement. This research aims to empower the knowledge of preservice biology teachers about the environment and its problems in environmental, and social contexts and cognitive skills to investigate and plan solutions to the issues. The quantitative research method with the one-group pretest-posttest design was employed to test the increase of environmental knowledge after learning. The nurturant effect is cognitive skills in overcoming environmental problems. The research participants consisted of 29 preservice biology teachers taking the environmental science course in the first semester. Environmental knowledge was measured using an essay test, while the measurement of cognitive skills was performed using a rubric with a rating scale based on the results of investigations of environmental problems in the field. It was found that the inquiry laboratory-based ethnosocioecology learning model could significantly improve environmental knowledge. In addition, environmental knowledge is positively correlated with cognitive skills. In general, cognitive skills increase with higher environmental knowledge.

**Keywords:** *cognitive skills, environmental knowledge, environmental literacy, ethnosocioecology, inquiry laboratory.*

## 1. INTRODUCTION:

Developing countries characterized by high population growth and economic instability encounter various environmental problems. These problems include pollution, deforestation, the decline in natural resources, climate change, and extinction. Declining environmental quality is a result of economic instability. The exploitation of natural resources to increase economic growth is not followed by efforts to rejuvenate the environment (Begon, Harper, & Townsend, 2006; Hanif & Gago-de-Santos, 2017). Indonesia is one of the developing countries with the fourth highest population in the world with Java as the most populous island. Pressure on clean water supply becomes one of the environmental problems found in densely populated areas. The clean water crisis is the impact of the conversion of green land into agricultural land, residential areas, mining, and industry. Flood is no longer a natural phenomenon, but a result of poor land management and spatial planning (Asian Development Bank, 2016).

Considering such conditions, concern for the environment should not only be a tendency towards attitude, but also be manifested in concrete actions (Mishra, Akman, & Mishra, 2014), one of which is to empower students in increasing their knowledge of the environment and applying it to overcome problems that are happening around them (Bodzin, 2016). Environmental education as an agent for formal learning is very effective for students to participate in sustainable development that prioritizes the environmental care aspect (Hoang & Kato, 2016; Varela-Candamio, Novo-Corti, & García-Álvarez, 2018).

One theme in 21<sup>st</sup>-century learning is environmental literacy (Pacific Policy Research Center, 2010) as a response to changes in environmental and socio-economic conditions. These changes stem from pressures due to population growth, urbanization, economic development, increasing inequality, and poverty rate (Delgado-Serrano, Mistry, Matzdorf, & Leclerc, 2017). Environmental literacy can be built through environmental education to gain in-depth knowledge, skills development, and authentic experience about environmental changes around students. More than that, students are expected to become part of a community that actively responds to the environmental crisis through concrete efforts (Coyle, 2005). Environmental education must use a multidisciplinary learning approach in order to produce a broad knowledge

of environmental science and skills to overcome environmental problems. Thus, environmental literacy is the highest goal of environmental education (Bodzin, Klein, & Weaver, 2010).

21<sup>st</sup>-century learning emphasizes mastery of higher-order thinking skills (HOTS) and complex cognitive processes (Greiff, Niepel, & Wüstenberg, 2015; Partnership for 21st Century Skills, 2009). These skills are supported by critical-thinking, problem-solving, communication, and collaboration so that individuals can adapt to various challenges in the globalization era (Saavedra & Opfer, 2012). Critical thinking and problem-solving are part of cognitive skills. Meanwhile, communication, collaboration, and social responsibility belong to interpersonal skills (Koenig, 2011). Creativity as a component of problem-solving skills is obtained when a person develops their thinking from various perspectives and is applied to new conditions (Partnership for 21st Century Skills, 2012).

21<sup>st</sup>-century learning is preferred to integrate approaches based on technology, inventions, problems, and HOTS (Partnership for 21st Century Skills, 2009). Growing technology facilitates students to work both independently and in groups. Technology helps in collecting relevant information, analyzing the relationship between information, constructing new knowledge, and presenting that information clearly from all aspects studied (OECD, 2008). In addition, technology is also used in the assessment of learning (Nikou & Economides, 2017). Students must be accustomed to finding answers to a problem by collecting and assessing the accuracy of the information, organizing information, and concluding (Griffin, McGaw, & Care, 2012; NAAEE, 2015).

Teachers at every level of education must possess in-depth knowledge and relevant experience relating to the environment, both the concept and the problem, before teaching the students (Nagra, 2010). This ability is significantly influenced by experiential learning such as learning that utilizes the natural environment, examines environmental problems, plays an active role in environmental management activities (environmental activists), and teaching practices on environmental education (Torkar, 2014). The important aspects to be considered in environmental education include learning relevant to everyday life, involving various parties such as society, family and role models, allowing students to interact with the social environment, direct experience, freedom to determine learning topics, studying local problems, and encouraging

community movements (Wilson, 2011). Given the importance of environmental education to improve environmental literacy in students, program or curriculum evaluations need to be carried out correctly to determine the progress, difficulties and the level of goal achievement (Spinola, 2015).

Therefore, the study aimed to empower the environmental knowledge and cognitive skills as the variables of the environmental literacy of preservice biology teachers.

## 2. LITERATURE REVIEW:

There are various definitions of environmental literacy and elements that make it up. According to NAAEE (2004), environmental literacy has four main components: (1) curiosity about the condition of the surrounding environment followed up by finding information, testing the truth and building a knowledge; (2) a deep understanding of human interaction with the environment; (3) measures to assess environmental problems and find solutions; and (4) awareness that each individual has a role to better change the environment. The first component consists of special skills, namely asking questions, designing investigations, gathering information, evaluating the truth of information, organizing information, reviewing and conducting simulations, and concluding and delivering explanations. The second component includes an understanding of the earth system, the concept of the environment, humans, and their culture and human interaction with the environment. The third component refers to the skills of analyzing and investigating environmental issues and making decisions. The fourth component includes understanding social values and principles, recognizing the rights and responsibilities as citizens, being confident and responsible for the actions taken (NAAEE, 2015).

According to Hollweg et al. (2011), the component of environmental literacy consists of knowledge, attitudes, competencies, and environmentally-responsible/friendly behaviors. Knowledge includes systems in physics and ecology and environmental issues. Attitude refers to sensitivity, environmental care, the motivation and purpose of taking action to deal with environmental issues. Competence emphasizes the skills and abilities to identify, analyze, create solutions, and evaluate actions to address environmental problems. Environmentally-responsible behavior is manifested in the form of individual or group involvement to overcome problems and prevent the emergence of new

conflicts such as environmental management activities, campaigning for environmental care, and using environmentally-friendly products.

The learning of environmental science is multidisciplinary (Miller & Spoolman, 2010). Students need to learn concepts related to ecology, economics, social, politics, and culture (NAAEE, 2015). The integration of diverse knowledge and scientific disciplines helps students analyze a problem from various perspectives. Not only do students need to master the concepts related to systems and processes that occur in the ecosystem, but they must also critically analyze how economic development, social and cultural changes, and environmental management policies can impact the environment (Kusmawan, O'Toole, Reynolds, & Bourke, 2009). Students need to be accustomed to exploring existing problems in the surrounding environment to grow their concern and awareness of the decline in environmental quality due to human interaction with the environment (Zareie & Navimipour, 2016).

The pilot study shows that the preservice biology teacher in the second semester still has a low or inadequate level of environmental knowledge. There is 63% of a preservice biology teacher who gets a score of less than six from 10 questions. Besides that, there is an inconsistency response, especially about the limitation of private land use and environmental protection of wildlife. Furthermore, the practice of environmental education needs to be improved to grow ecological literacy through the understanding of the environment and its problem and real action to respond to the environmental changes surroundings.

Developing environmental knowledge means increasing environmentally-friendly behavior as it reflects the level of one's environmental knowledge (Zareie & Navimipour, 2016). Educational institutions and the government can collaborate to increase students' knowledge about the environment that refers to the ecological and social context. Through formal efforts, the government mediates the community with academics to collaborate, share information, and conduct research. Thus, various parties contribute to achieving a balance between social and ecological aspects and sustainable development goals. Information and research results are then used as learning content for the development of environmental knowledge, stimuli of changes in environmentally-friendly behaviors, and empowering skills to cope with changing environmental conditions (Krasny, Lundholm, &

Plummer, 2010).

Individuals who care about the environment not only have a deep understanding of environmental problems and issues but also master cognitive skills in addressing environmental problems (Hollweg et al., 2011). Cognitive skills involve students to use their prior knowledge to solve new problems and build new knowledge. Students need to actively explore a problem, apply the knowledge they have learned leading to the discovery of ideas or new problem-solving strategies. Cognitive skills involve the ability to think critically to specify the problem and connect a variety of information and the ability to think creatively to find effective and innovative solutions (Koenig, 2011).

One's action on the environment from the Theory of Reasoned Action perspective is influenced or determined by several factors. The fundamental factors in determining a person's behavior include personal, social, and knowledge background factors. These factors affect one's belief in behaviors and norms that exist in society. A person's trust determines his/her attitude towards a behavior and norm and behavior control. Attitudes, norms, and behavioral control further determine or influence the purpose of an action. Through learning environmental science, students are expected to utilize their prior knowledge of the environment to be transferred into positive attitudes and behaviors towards the environment (Fishbein & Ajzen, 2010).

Applying knowledge to do a set of cognitive skills in problem-solving is an example of experiential learning. Inquiry learning is one example of experiential learning that helps students connect theory with practice. Prior environmental knowledge is enriched through the activities of investigating environmental problems in the field. The prior knowledge and knowledge gained during the investigation are interrelated to test the truth of the previous knowledge. New knowledge that is built through the process of finding information, observing, measuring, and analyzing is utilized as a new stimulus to make decisions in similar new situations. Also, the inquiry method in environmental science learning trains students to reason according to the evidence obtained during the activities of problem identification, gathering facts of the problem, planning problem-solving actions, predictions, making relevant decisions, and linking problems with the specified solutions (Dewey, 1938).

Inquiry laboratory learning is also one example of the application of meaningful learning

theory. Students build new knowledge by organizing the entire prior knowledge with the information being studied (Savin-Baden & Major, 2004). The previously-owned knowledge is adjusted to new conditions or problems in order to produce creative ideas, for example in overcoming the problem of pollution or waste (King, Keohane, & Verba, 1995). Students not only get concepts available in the form of textbooks but also learn to explore information in the field, analyze, organize, and make conclusions about environmental problems and the solutions (Ausubel, 2000).

Environmental science is interdisciplinary. Various disciplines are interconnected, for example in handling fisheries problems. To address these problems, they need to be studied from the aspects of environmental economics, political science, ecology, chemistry, anthropology, and population biology. Explaining the environmental problems at the beginning of the learning is expected to stimulate students' ability to reason from various perspectives and to recall the knowledge or experience they have. Different opinions of the students with heterogeneous academic and communication skills help them in the transfer of knowledge, enriching insight, and cognitive development in social interaction (Vygotsky, 1978). Environmental science learning in study groups encourages students to exchange opinions, consider the advantages and disadvantages of planned solutions, and make decisions based on mutual agreement (Swartz & McGuinness, 2014).

According to the socioecological theory of systems, there is a close relationship between social systems and ecology. Besides living and forming community groups, humans also depend on nature to get ecosystem services (Patten, 2016). This system aims to safeguard and enhance ecological resilience in supporting human survival by continuing to prioritize ecological principles in adaptive ecological management (Mathevet, Thompson, & Folke, 2016). This system is useful for the identification of causal relations between components in ecology and social to produce a mechanism to adapt to changes that occur in both systems (Kappeler, 1999). Local knowledge is one form of adaptive ecological management (Pauli, Abbott, Negrete-Yankelevich, & Andres, 2016).

Knowledge about the environment consists of scientific knowledge and local knowledge. The combination of both kinds of knowledge contributes to reducing the possibility of environmental damage as a result of the use of the environment (Mercer, Dominey-Howes, Kelman, &

Lloyd, 2007; Thornton & Scheer, 2012). Traditional ecological knowledge is obtained from the habit of people interacting with nature directly, including knowledge about living things and natural phenomena, as well as how to manage the environment such as farming, raising livestock, and hunting (Inglis, 1993). Local knowledge arises and develops among the people who have lived in an area for a long period and retained it because it provides benefits for their life and environment. Although local knowledge is not obtained through scientific testing, the truth of the knowledge can be scientifically proven through integrated science learning (Parmin, Sajidan, Ashadi, Sutikno, & Fibriana, 2017).

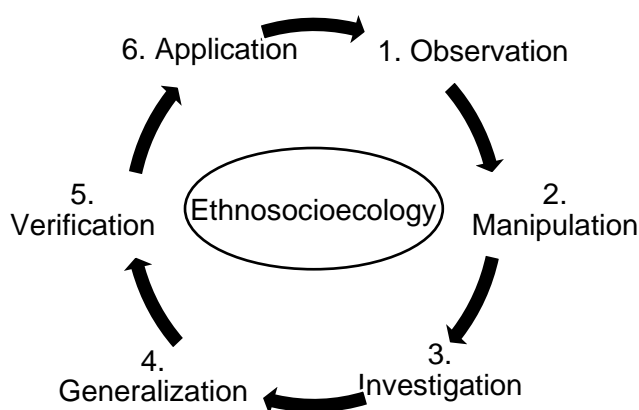

The use of local knowledge in environmental education can enrich the knowledge of preservice biology teachers related to sustainable environmental management practices. Students are encouraged to participate in overcoming global problems by utilizing local knowledge in their surroundings (Palmer, 2003). Ethnoecology is also called local knowledge, traditional knowledge, or traditional environmental knowledge, which is often used interchangeably. Ethnosocioecology is a set of knowledge and perceptions of local people in environmental management practices to adapt to changes in ecological and social systems.

Integrating local knowledge about the environment in learning has several advantages: (1) it completes and provides reinforcement about science that can generate new thinking and develop problem-solving skills (Evering, 2012); (2) it raises awareness about local knowledge; (3) it facilitates students to develop critical-thinking skills; (4) it fosters cooperation with local communities to create sustainable communities (Dei, 2000).; (5) it strengthens the character education of students (Adilah & Saputra, 2013; Marhayani, 2016); (6) it improves problem-solving skills, scientific investigations and environmental care attitudes (Dewi, Poedjiastoeti, & Prahani, 2017); and (7) it helps students apply and transfer their knowledge to everyday life (Gitari, 2010).

The inquiry laboratory is the fourth level of inquiry after discovery learning, interactive demonstration, and inquiry lessons. Inquiry laboratory has a characteristic that is to demand the independence of students in exploring their knowledge and the locus of control is entirely on students. Students are given the freedom to determine the problems and procedures used in inquiry and problem-solving. Lecturers act as facilitators who provide opportunities for students to conduct investigations and provide support or

assistance only when needed because college students are adult learners who already have the psychological ability to study independently (Flick & Lederman, 2006). The main objective of laboratory inquiry-based learning is to formulate empirical laws based on measurements of variables. The process skills needed in this research include measurement, formulation of empirical laws based on evidence and logic, designing scientific investigations using technology, and calculating (Wenning, 2005; 2010; Wenning, Khan, & Khan, 2011). However, not all students have the same level of process skills in testing or collecting data. Therefore, in this research, students are provided with guiding questions or points that need to be studied as guidance in conducting investigations. Meanwhile, problem-solving planning is entirely determined by students according to their level of critical thinking and creativity.

The inquiry laboratory-based ethnosocioecology learning model consists of observation, manipulation, investigation, generalization, verification, and application stages. The observation stage is the identification of problems in the classroom from the guiding questions raised by students under the topic or theme of learning. Based on the identified problems, students determine one main problem and design a problem investigation procedure (related to the environment) independently at the manipulation stage. The draft includes determining the location of the investigation, compiling a list of questions to gather information directly from the local community related to the topic of the problem, and planning or predicting problem-solving actions. The next stage is the investigation. Students carry out investigation activities in the field according to plan. After obtaining information through interviews and observations, students analyze the problem including the causes and effects supported by the study of relevant theories and determine solutions relevant to the problem. In the generalization stage, students formulate conclusions based on the data analysis. The problems investigated and analyzed are presented in discussions to get various information and responses from other students. This stage is called the verification stage. The application stage is the implementation of the conclusions from the results of the discussion as reinforcement and confirmation of the truth about students' prior knowledge related to environmental problems to solve problems in new situations or answer questions (Figure 1).

**Figure 1.** *The model of inquiry laboratory-based ethnosocioecology*

In addition to the independence that takes precedence in inquiry laboratory learning, the use of local knowledge content is the basis for students in conducting the stages of inquiry laboratory. Before students determine the environmental problems to be studied, they explore prior knowledge related to local knowledge on the use or management of the environment, components contained in local knowledge (knowledge, practice, and beliefs), how local knowledge arises and is transmitted over generations, and the benefits of applying local knowledge to environmental sustainability. Apart from being used to increase students' knowledge about the environment, local knowledge is also used as a basis for students to develop ideas for solving environmental problems that are further investigated. Thus, students indirectly prove the truth of local knowledge related to its role in environmental preservation.

### 3. MATERIALS AND METHODS:

To test the effect of inquiry laboratory-based ethnosocioecology learning model on the empowerment of environmental literacy, one-group pretest-posttest design was used. Before conduct the study, the researcher submits the research permit that known by the supervisor and approved by the faculty to the head of the biology education study program. The document was forwarded to the practitioner and discuss the form of collaboration between practitioners, students, and researchers along with the study. The sample consisted of 29 preservice biology teachers. As the environmental literacy construct that has been previously defined, which is a set of knowledge about the environment and its problems in ecological and social contexts and cognitive skills in problem-solving, the environmental literacy in this research consists of two variables that are

environmental knowledge (EK) and cognitive skills (CS). This research was conducted in 5 cycles (two meetings of each cycle). In each meeting, there were 29 preservice biology teachers, a practitioner/lecturer, and three observers.

Each meeting lasts for 100 minutes in the classroom. As shown in Figure 1, the syntax of inquiry laboratory-based ethnosocioecology consists of six syntaxes. In each cycle, students investigate one topic of environmental problems and design a solution. The activity of the first meeting in each cycle is observation and manipulation. Environmental problems and local knowledge that have been identified in the classroom are followed up with investigation in the field. Preservice biology teachers do the investigation and generalization syntaxes in the field. The specific problem was investigated and analyzed deeply and designed the solution. The result of field investigation was presented in a paper which consists of problem identification, problem investigation, problem analysis, and solution. Practitioners and biology preservice teachers communicate within a WhatsApp group during field investigation. Students and the lecturer could discuss the difficulties and share the information at the field in the form of pictures or videos, and the lecturer and observer could control the student progress and activity. The second meeting of each cycle is for verification and application syntax. The student reports the field investigation and solution then discuss it with other groups. The observer records the activity of learning such as how the implementation of each syntax, what difficulties, and learning progress.

The materials used in the learning module include (1) introduction to environmental science and ethnosocioecology, (2) environmental principles and ecosystem management models, (3) ethnosocioecology as an example of the application of environmental ethics, (4) components and processes in the ecosphere, and (5) ecosphere problems and the resolution efforts. Investigation topics related to these materials include (1) the problem of green land conversion, (2) environmental management and problems, (3) examples of local knowledge as a form of environmental ethics, (4) carbon cycle disruption, and (5) local environmental problems. These topics encourage students to dig deeper information from various viewpoints, experiences, and public knowledge, and observe environmental conditions directly. Students analyze the data collected with relevant theoretical studies. Based on the facts and study of the theory, students find reinforcement and confirmation of the truth related

to environmental issues that have been the subject of the global discussion. Investigation of local knowledge in the community enables students to think locally and act globally or encourages them to solve global problems by utilizing the local potential around them.

Preservice teachers were given a pretest before learning and posttest after completing learning in each cycle. Pretest and posttest were used to measure students' environmental knowledge. Pretest and posttest were given in the form of description questions that had been tested for validity and reliability. In addition to providing tests, the researcher also assessed students' cognitive skills in solving environmental problems. Cognitive skills were assessed using a rubric with a rating scale. There are 4 indicators of cognitive skills, namely problem identification, problem investigation, problem analysis, and problem-solving. These indicators were assessed through the paper resulted from field investigation. Each indicator was assessed by four rating scales 1 = unclear and irrelevant, 2 = slightly unclear and irrelevant with the problem, 3 = clear but slightly relevant to the problem, 4 = clear and relevant to the problem.

T-test was used to determine differences before and after learning inquiry laboratory-based ethnosocioecology on environmental knowledge. Before conducting the test, the data were tested for normality and homogeneity as prerequisites. To find out whether there is a positive correlation between environmental knowledge and cognitive skills, Pearson's correlation test is performed. Before the data correlation test, the data linearity and normality were tested.

#### 4. RESULTS AND DISCUSSION:

Based on the results of the normality test using the Kolmogorov-Smirnov test, the pretest and posttest data in the five cycles showed normal distribution of data ( $p > 0.05$ ) and based on the homogeneity test using Levene test, the data were homogeneous ( $p > 0.05$ ) (Tables 1 and 2).

The cognitive-skill data in the five cycles also showed normal distribution and had homogeneous variants as well as significant values of more than 0.05 (see Table 3 and 4).

After the prerequisite tests were fulfilled, the data were analyzed using paired t-test to find out whether there are significant differences before and after the application of inquiry laboratory-based ethnosocioecology on students' environmental knowledge. The data from the five

cycles were used in the paired t-test. The analysis showed that there was a significant difference between before and after the treatment ( $p < 0.05$ ) (see Table 5). Thus, the inquiry laboratory-based ethnosocioecology learning model is effective in empowering environmental literacy.

Cognitive skills were measured using an assessment rubric based on the results of investigations of environmental problems and the resolution efforts. The linearity test results from the five cycles showed that the value of deviation from linearity is more than 0.05. This means that environmental knowledge and cognitive skills have a linear relationship. After the prerequisite tests were met, the data were tested using the Pearson correlation. The Pearson correlation test results show a positive correlation coefficient close to 1 with a significance value of less than 0.05 (see Table 6).

This means that environmental knowledge and cognitive skills are positively correlated. In general, higher environmental knowledge will be followed by an increase in cognitive skills. Based on the results of the t-test, it was found that the inquiry laboratory-based ethnosocioecology learning model is effective in increasing environmental knowledge. Higher environmental knowledge will lead to an increase in cognitive skills in solving problems.

In cycle 1, the experimental-class students investigate problems related to the conversion of land use for the batik industry, tourism, shops, housing, and infrastructure. In cycle 2, students study problems regarding environmental management for animal husbandry, tourism, agriculture, and household waste treatment plants. In cycle 3, students investigate examples of local community knowledge in farming, namely the use of straw in growing rice seedlings, crop rotation, polyculture planting systems on private land, and terracing systems. In cycle 4, students conduct interactive simulation activities on carbon cycle disruption and food webs and create a design to overcome these problems. In cycle 5, students study environmental problems that have long been experienced by residents, namely water pollution and waste problems. Students analyze and communicate the results of investigations and design solutions obtained at the second meeting in each cycle.

Various solutions are produced after students analyze the problem. In cycle 1, one of the solutions designed is the use of natural materials from plants such as leaves, flowers, stems or roots, and others as natural batik dyes. The natural batik dyes can reduce water pollution

due to the batik industry with harmful chemical dyes. In connection with the problem of environmental management for cattle farming, namely livestock manure, in cycle 2, students plan a strategy in the form of using animal dung to be made composted and to be made biogas. In cycle 3, relating to examples of local knowledge, students prove the use of straw in increasing soil fertility and moisture applied in the practice of growing rice seeds. Also, students examine the effect of crop rotation and polyculture systems on soil fertility.

In cycle 4, students simulate the carbon cycle for carbon cycle disturbance material. Interactive simulations, instead of investigations in the field, involve students actively in changing certain parameters and observing changes that occur. The data collected are then analyzed to build new knowledge. Through these simulations, students can understand the process of the ongoing carbon cycle, carbon distribution in the ecosphere, and the influence of increased use of fossil fuels and carbon levels on the survival of life on land and water. After analyzing the problem, students create the design of the solution to overcome the carbon cycle problems while still referring to local environmental management practices.

In the simulation of food webs, students practice making predictions of the increase or decrease in the number of producer and consumer populations in an ecosystem. Then, they prove their predictions through simulations and make modifications to the food webs so that each trophic can maintain their survival in the ecosystem. The results of the investigation through simulations are generalized and verified in class discussions. Communicating the results of the simulation also becomes a medium for students to compare the results of their investigations with other study groups.

In cycle 5, they examine the ecosphere problem and its solution. Students study water and garbage pollution problems. Through the activities of problem identification, problem investigation in the field, literature studies, and problem analyses, students can create a water pollution problem-solving plan by utilizing natural materials namely Moringa plant seeds from the surrounding environment combined with a simple screening tool. For the garbage problem, students design solutions by replacing plastic bags with cloth bags that can be used repeatedly, using plastic waste as chairs or tables made up of eco-bricks, and processing cardboard waste into reusable items such as makeup equipment, mini cabinets, tissue

holder, and stationery.

Based on the test results in cycles 1 to 5, there is an increase in the average posttest scores in the experimental class. This shows that the ability of students to analyze and evaluate problems related to environmental management is increasing in each cycle. Besides, there is an increase in the students' ability to solve environmental problems with information obtained during the study group's investigation and discussion. After the paired t-test, it was found that there is a significant difference between the means of the posttest and pretest of environmental knowledge in the experimental class.

Based on the results of the Pearson correlation test, it is known that there is a significant positive correlation between environmental knowledge and cognitive skills. This shows that the high value of environmental knowledge, in general, is followed by the high value of cognitive skills. Thus, the inquiry laboratory-based ethnosocioecology learning model is effective in empowering environmental literacy for the aspects of environmental knowledge and cognitive skills.

Learning activities that examine the problem of land-use conversion, environmental management problems, environmentally-friendly management practices, simulation of material cycle disturbances, and environmental problem resolution help students develop their environmental knowledge (Partanen-Hertell, et al., 1999). Students practice connecting the causes and effects of environmental problems from observation and investigation activities (Erdogan, 2015). Multidisciplinary environmental science encourages students to evaluate the relationship between ecological and social aspects that contribute to the emergence of environmental problems (Steg & Vlek, 2009). Understanding these relationships becomes the basis to apply their knowledge critically in the face of environmental changes that occur (Sorensen et al., 2015). Student-centered learning activities reinforce environmental care (Bissinger & Bogner, 2017).

Studying local knowledge applied by the community such as crop rotation, intercropping system, and using straw in the farming system can foster students' awareness that the practices carried out by local communities need to be preserved. Insights into the benefits of local knowledge encourage students to develop ideas for solving environmental problems that are environmentally friendly that do not lead to new

problems and reduce the environmental damage caused by the existing technological development (Kimmerer, 2012). Learning through direct experience in the field contributes to building knowledge about the environment (Brenner, Hamilton, Drake, & Jordan, 2013; Stevenson et al., 2014).

Students' cognitive skills improve from cycle 1 to 5. The stimuli given in the form of environmental issues encourages students to have group discussions (Savin-Baden & Major, 2004). Students are trained to convey their knowledge, experience, and ideas related to issues that are of concern around them. Investigating environmental problems helps students connect their prior knowledge with information being learned to build new knowledge. Contextual learning contributes to linking theory with practice (Agung, 2015; Reyes-García et al., 2010).

Studying environmental science is not enough to master the concepts of the environment, but it is very important to deepen understanding of environmental issues or problems. An understanding of the environmental conditions around them is expected to lead students to take action. Investigation of environmental problems in the field begins with identifying the problem. Problem identification helps students determine specific problems to be studied further by gathering information in the field. The data obtained are then analyzed to deepen understanding of the cause and effect relationship. The analysis of the problem is then followed up by finding relevant and applicable solutions (Bodzin, Klein, & Weaver, 2010).

The lecturer acts as a facilitator when the students plan and carry out investigation activities. The lecturer actively accommodates students' ideas in preparing investigation plans. When students find it difficult to determine the specific topic to be studied, the lecturer provides an example of his previous experience so that students have a picture and can make decisions. Also, the lecturer provides an immediate response whenever the student needs opinions related to the topic to be further investigated. The lecturer encourages the freedom and independence of students in designing investigation activities while still providing space for discussion. The facilitation used is in the cooperative form (Heron, 1989; 1993).

During the observation and manipulation activities, verbal strategies are applied by the facilitator. The first strategy is giving questions to

train students to express ideas or prior understanding of the issue being discussed. The second is providing support and trust that students can convey their prior knowledge. The third is providing conclusions on the ideas or answers given. The fourth is giving back the questions of the students to be answered or responded by others. It aims to raise students' responsibility to explore their knowledge. In addition, verbal strategies are also carried out during manipulation and investigation. The lecturer suggests alternative ideas when students find it difficult to make decisions and control the progress of study groups in planning and conducting investigation activities (Savin-Baden & Major, 2004).

Study groups with diverse cultural backgrounds and cognitive skills facilitate students in developing their cognitive skills by sharing knowledge and experiences and help them to make adjustments to their environment (Griffin et al., 2012). The same goal to solve environmental problems with the basis of knowledge on local environmental management encourages students to discuss their prior knowledge with one another in class and link the ideas of all group members. Through the process of interactions and dialogs, students can make decisions to take action (Savin-Baden & Major, 2004).

Getting students used to study environmental problems that occur around them and to design solutions-oriented to local knowledge is pivotal in learning environmental science. Students master not only knowledge about the environment, but also skills to solve problems and foster the environment care attitude. Studying environmental problems facilitates students to get used to gathering information related to facts in the field. Based on the information obtained, students learn to develop opinions or determine attitudes towards environmental problems that occur. In addition, students are involved in linking various information about the environment, analyzing the interrelationships of causes and effects of environmental problems, and designing strategies in overcoming environmental problems (Palmer & Neal, 1994).

The integration of traditional or local knowledge in environmental science learning contributes positively (Kimmerer, 2012). First, students can get to know the traditions or habits of environmental management that have been practiced by previous generations. Second, students understand the benefits and importance of applying traditional environmental management practices to the current deteriorating

environmental conditions (Brenner et al., 2013). Third, students gain new knowledge during the process of verifying the truth of local knowledge (Hiwasaki, Luna, Syamsidik, & Shaw, 2014). Fourth, students learn to integrate local and scientific knowledge to design innovative solutions (Makondo & Thomas, 2018; Torri & Laplante, 2009). Fifth, students contribute to preserving local environmental management practices as part of cultural wealth (McCarter & Gavin, 2011). Sixth, students learn to understand the meaning of sustainable living by applying traditional management practices (Dahliani, 2015; Sumane et al., 2017).

## 5. CONCLUSIONS:

Environmental literacy is an urgent demand given the current conditions of the environmental crisis. Environment care and its problems must be instilled in each individual because human is naturally an inseparable part of nature. Growing an attitude of caring for the environment must be done in concrete action. Education as a formal environment, for example, must be able to contribute to the generations that have insight into sustainable development. One strategy is to instill an environmental care attitude through learning. Interdisciplinary learning of environmental science must be able to empower students to be active in studying environmental issues, expressing opinions from a variety of perspectives, analyzing the interrelationships among environmental problems, evaluating the truth of information from various sources, and developing innovative strategies. Inquiry laboratory-based ethnosocioecology learning is one of the strategies to involve the active role of students as independent learners in building new knowledge. New knowledge is obtained by analyzing, linking, organizing prior knowledge with information being learned in the classroom, and the surrounding environment. Students deepen their understanding of environmental issues through investigations in the field, testing the truth of local knowledge, linking the concepts of local knowledge with the conditions of environmental problems, and designing appropriate strategies. Environmental science learning through real experience is not merely memorizing existing concepts. It also allows students to learn to dig up information, to communicate, and interact with peers and the surrounding community, and to argue based on the evidence. Studying the surrounding environmental problems and learning local knowledge practices in managing the

environment, in addition to increasing knowledge about the environment, can also develop the cognitive skills of students in solving problems. Solving environmental problems is one manifestation of the environmental care attitude.

## APPENDIX

### *Questions to Measure the Environmental Knowledge*

---

#### **Cycle 1**

---

1. Environmental science is multidisciplinary. For example, the problem of decline in fisheries productivity involves collaboration from various science experts to overcome it. Why is that?
  2. Waste that pollutes the mangrove ecosystem area has an impact on increasing coastal abrasion. Besides, the decline in crab and shrimp productivity has a significant effect on the decline in income of the local community. What is the role of environmental science in efforts to improve the economic welfare of coastal communities?
  3. Local people living on the slopes of Mount Lawu reject the plan to use geothermal energy to become a geothermal power plant. What factors underlying the rejection of the use of geothermal energy to be used as a geothermal power plant were assessed from the aspect of ethnosocioecology?
  4. Land areas inhabited by local people have a high level of biodiversity. Why do cultural values play a role in protecting biodiversity?
  5. Economic growth in Indonesia increase in 2018. Gross Domestic Product (GDP) reaches 5.17%, up from 5.07% from the previous year. Java Island still contributed to the growth of gross domestic product by 57.8% (the largest), followed by Sumatra by 23.4%. On the other hand, environmental conditions in Java, especially in densely populated areas, are already alarming. Likewise, the problem of land conversion continues to increase in Java and Sumatra. What is the impact of increasing economic welfare on the environment in Indonesia?
  6. Currently air and water quality in almost all regions of big cities are very poor. Based on the results of the Ministry of Environment research, the air quality index in the DKI Jakarta area is the lowest (53.5) compared to other regions in Indonesia and far below the air quality index national level (87.03). In addition, DKI Jakarta's water quality index was 21.33 and DI Yogyakarta was 20.19. Both are far below the national water quality index which is equal to 58.68. Why is the problem of natural resources not free from population density?
  7. How to use water more efficiently in the middle to upper-income groups in daily life?
  8. What steps need to be taken so that the water supply continues to meet daily needs per person in all social strata?
- 

#### **Cycle 2**

---

1. Java is the island with the largest population of 136.6 million people with a population growth rate of 1.21% per year over the period 2000-2010. Why is a densely populated area such as DKI Jakarta often there is a limited supply of resources?
  2. BNPB showed that the conversion of forest land in Java to agricultural land can cause deviations from the principle of natural resources. Analyze the deviations in the principle of natural resources that occurred in the case.
  3. Ecosystem management is an integrated approach that involves
-

---

social, economic, ecological, and institutional perspectives. Why does ecosystem management need to involve various parties living around the ecosystem, resource users, decision-makers, people's representatives, and taxpayers?

---

4. Decision making of environmental management policies needs to involve various parties. Why are local people as one of the important actors in making decisions about environmental management?

---

5. Production forest management as one of the natural resource management policies involves communities around the forest to be able to apply the forest management paradigm and produce products based on local businesses that can compete and be accepted in the global market. Do you think that the policy meets the principles of environmental science?

---

6. Social forestry management is a natural resource management policy to improve the welfare of life for indigenous and tribal peoples. Does the policy meet the four principles of environmental science? Explain your answer

---

7. What is the action that must be taken by the community and the government if the watershed experiences a water quality crisis and habitat degradation due to land management for agriculture and animal husbandry that is not environmentally friendly?

---

8. In 2001 the local government of Nagekeo, Kupang received a refusal from the local community to build the Lambo reservoir. What is the form of approach that should be used to form good cooperation in environmental management between local communities and the government?

---

### **Cycle 3**

---

1. Why is the understanding of biocentrism considered insufficient as the highest guide in behaving and acting towards the environment as evidenced by the emergence of ecocentrism?

---

2. Kemiren Village in Banyuwangi, East Java has the Sobo River and Gulung River which are to the south and north of the village and never dry throughout the year. Also, there is a spring that is protected and preserved by residents, namely the great-grandfather of Chile. One of the rules imposed is a ban on using source water on certain days and hours and cutting down trees around springs. Why do watersheds need to be managed properly without prioritizing human interests?

---

3. What is the real form or example of anthropocentrism in daily activities that can have an impact on environmental damage (water/land area)?

---

4. Kampung Naga people, Dayak, and Banjar tribes have a tradition of land distribution for residential zones, farming zones, protected zones, and sacred zones. Why do local land divisions and land use arrangements need to be preserved?

---

5. Dayak tribes who live in Kalimantan implement a system of land rest in farming. Meanwhile, the people of West Kutai, East Kalimantan have implemented the Lembo System, which is a mixture of fruit forests and timber. Based on these examples, how can local knowledge apply the principles of environmental ethics?

---

6. The division and arrangement of land is an example of local knowledge of Kampung Naga and Kampung Kuta, which consists of

---

---

clean, sacred, and dirty areas. What is the principle of environmental ethics contained in this knowledge?

---

7. Create a plan to purify the water based on the local knowledge of your home.

---

8. Create a plan to increase the fertility of the land-based on the local knowledge available in your home.

---

#### **Cycle 4**

---

1. The food chain is composed of 4 trophic levels, namely 1-producer trophic level, trophic level 2-consumer 1 (herbivore), trophic level 3-consumer 2 (omnivore), and trophic level 4-consumer 3 (top predator). Why is there a level 2 consumer at the trophic level, omnivorous?

---

2. In a food chain, there is an energy flow from one trophic level to another trophic level. Why the more trophic levels, the less amount of biomass?

---

3. In the period of 2000-2014, Indonesia was recorded as a contributor to the loss of the largest mangrove forest in the world at 4,364 km<sup>2</sup> or around 311 km<sup>2</sup> per year. One of the threats to the decline in mangrove forests is the expansion of brackish water ponds in coastal areas for shrimp and milkfish commodities. How can brackish water ponds business affect the energy flow and material cycle?

---

4. Based on a study conducted by the World Bank, coal extraction has a serious impact on the environment and communities around the mining area. Why does mining disrupt the phosphorus cycle and cause damage to freshwater ecosystems?

---

5. The United States Department of Agriculture explains that globally 1/3 of human food is obtained from plants whose pollination is assisted by bees. In 2008, it was recorded that 36% of bee colonies were lost. The incident was caused by the use of pesticides. How is the impact caused by the decline in bee populations?

---

### RESUMO

O uso prolongado de aspirina para prevenção de eventos cardiovasculares é limitado por seus efeitos adversos gastrointestinais e, portanto, pacientes com alto risco devem receber agentes gastroprotetores. No entanto, os medicamentos gastroprotetores também apresentam alguns efeitos adversos que exigem a busca de alternativas seguras e eficazes. Os compósitos que combinam as propriedades de intumescimento das argilas e a atividade biológica dos polissacarídeos parecem ser candidatos promissores à proteção do trato gastrointestinal. O objetivo deste estudo foi caracterizar compósitos de pectina / montmorilonita e avaliar seu efeito protetor no trato gastrointestinal de ratos em uso de aspirina por um longo período. Uma série de compósitos à base de montmorilonita (MMT) e pectina com baixa esterificação (Pec) foi sintetizada usando o método de adsorção-precipitação. As razões de peso de polissacarídeo para argila foram 1:19, 1: 9 e 1: 4. Os compósitos foram caracterizados por Análise Termogravimétrica (TGA), Espectroscopia no Infravermelho (IR), Microscopia Eletrônica de Varredura (MEV) e Difração de Raios-X (DRX). A pectina foi completamente fixada em MMT e o teor de polissacarídeos nos compósitos foi de aproximadamente 5, 10 e 20% em peso, respectivamente. O deslocamento da banda de absorção do grupo C = O da pectina indicou a interação do polissacarídeo com a argila, confirmando a imobilização efetiva do Pec no MMT. A modificação com pectina alterou a morfologia e a estrutura do MMT devido ao revestimento superficial e à intercalação no espaço entre camadas. Os compósitos incharam em água acidificada (pH = 2,0) e a capacidade de intumescimento foi maior para comparar com o MMT não modificado. A capacidade de sorção dos compósitos Pec / MMT em relação ao ácido acetilsalicílico (ASA) diminuiu de 6,8 para 1,0 mg g<sup>-1</sup> com o aumento do conteúdo de pectina de 5 para 20% em peso. Os compósitos híbridos promoveram proteção do trato gastrointestinal de ratos, aos quais foi administrado ASA com Pec / MMTs por um período de 16 dias. As propriedades protetoras do Pec / MMT foram aprimoradas com o aumento do conteúdo de pectina de 5 a 20% em peso.

**Palavras-chave:** *pectina, MMT, aspirina, doença intestinal, propriedades protetoras.*

### ABSTRACT

Long term use of aspirin for prevention of cardiovascular events is limited by its gastrointestinal adverse effects, and, therefore, patients at high risk should receive gastroprotective agents. However, gastroprotective drugs also have a few adverse effects that require searching for safe and effective alternatives. The composites combining the swelling properties of clays and the biological activity of polysaccharides seem to be promising candidates for gastrointestinal protection. This study aimed to characterize pectin/montmorillonite composites and evaluate their protective effect on the gastrointestinal tract of rats taking aspirin over a long period. A series of composites based on montmorillonite (MMT) and low esterified pectin (Pec) was synthesized using the adsorption-precipitation method. The polysaccharide to clay weight ratios were 1:19, 1:9, and 1:4. The composites were characterized using Thermogravimetric Analysis (TGA), Infrared Spectroscopy (IR), Scanning Electron Microscopy (SEM), and X-Ray Diffraction (XRD). Pectin was completely fixed on MMT, and the polysaccharide content in the composites was approximately 5, 10, and 20 wt%, respectively. The shifting of the absorption band

of the C=O group of the pectin indicated the interaction of the polysaccharide with the clay, confirming effective immobilization of Pec on MMT. Modification with pectin changed the morphology and structure of the MMT due to the surface coating and intercalation into the interlayer space. The composites swelled in acidified water (pH = 2.0), and their swelling ability was higher to compare with unmodified MMT. The sorption capacity of Pec/MMT composites towards acetylsalicylic acid (ASA) was decreased from 6.8 to 1.0 mg g<sup>-1</sup> with increasing of pectin content from 5 to 20 wt%. The hybrid composites promoted the protection of the gastrointestinal tract of rats, which were administered ASA with Pec/MMTs for 16 days. Protective properties of the Pec/MMT have been improved with increasing pectin content from 5 to 20 wt%.

## 1. INTRODUCTION:

Acetylsalicylic acid (ASA, aspirin) is now a commonly used drug for the prevention of cerebrovascular and cardiovascular diseases (CVD) (Iijima, 2016; Ali & Sharma, 2018). However, daily aspirin therapy, even at a low dose, can damage the gastrointestinal tract (GI), causing Crohn's disease and ulcerative colitis (Moninuola *et al.*, 2018; Bjarnason *et al.*, 2018). This may lead patients to discontinue therapy, increasing their CVD risk (Lavie *et al.*, 2017). Co-administration of proton pump inhibitors (PPIs) in patients taking aspirin reduces the risk of aspirin-induced upper GI adverse events (Rodriguez *et al.*, 2020). However, PPIs also have adverse effects such as allergic reaction, diarrhea, changed gut microbiome, fundic gland polyp, drug interaction in the gut, etc. (Kinoshita *et al.*, 2018; Fossmark *et al.*, 2019). This requires a search for safe and effective alternatives to PPIs.

The composites combining the properties of clays and polysaccharides seem to be promising candidates for GI protection. The mineral component of such composites (clay) can act as antacid reducing the gastric acidity through adsorption of protons and release of non-toxic ions such as Mg<sup>2+</sup> and Al<sup>3+</sup> (Massaro *et al.*, 2018). The ability of natural clays to adhesion on the gastrointestinal mucosa surface, causing increase barrier thickness, is also of interest (Massaro *et al.*, 2018; Ali *et al.*, 2017). Modification of the layered silicates with polysaccharides can improve their mucoadhesive properties (Sharma *et al.*, 2018). Besides, non-starch polysaccharides provide many benefits for intestinal bowel disease treatment, including tissue healing, anti-oxidation, reduction of toxins adsorption, modulate gut microbiota, etc. (Nie *et al.*, 2017). Of note is that certain gut bacteria ferment the polysaccharides to produce short-chain fatty acids (SCFAs), which maintain the epithelial barrier function and protect against colitis (Zhang *et al.*, 2018). Biocompatible and non-toxic polysaccharide/clay composites are widely used for biomedical applications as drug

delivery systems, tissue engineering scaffolds, wound dressings and detoxifying agents (Wu *et al.*, 2019; Liu *et al.*, 2017). However, such composites have practically not been studied on alleviating ailments caused by the administration of nonsteroidal anti-inflammatory drugs (Dragan & Dinu, 2020; Meirelles & Raffin, 2017).

Long-term co-administration of pectin/montmorillonite intestinal adsorbent with aspirin in rats has previously been shown to possess a positive effect on their blood biochemical parameters (Kapysheva *et al.*, 2019). Therefore, this study aimed to characterize pectin/montmorillonite composites synthesized using a simple adsorption-precipitation method and evaluate their protective effect on the gastrointestinal tract of rats taking aspirin over a long period.

## 2. MATERIALS AND METHODS:

### 2.1. Materials

Montmorillonite (MMT), from the Tagansky deposit (Kazakhstan) produced by Sorbent (Ust-Kamenogorsk, Kazakhstan), and ethanol (96.3%), purchased from Talgar Spirt (Kazakhstan), was used without additional purification. Acetylsalicylic acid, obtained in tablet form from the Borisov Plant of Medical Preparations (Belarus), was separated from the other ingredients using recrystallization with ethanol as the solvent.

### 2.2. Extraction and characterization of pectin

Extraction of the pectin (Pec) from ripe Golden Delicious apple pomace (5 g) was carried out using water acidified with citric acid (pH = 2.0) at 80 °C for 4 hours according to the procedure described in (Devi *et al.*, 2014). The pectin yield (Y<sub>Pec</sub>) was calculated using the following equation (Eq. 1).

$$Y_{Pec}(\%) = \frac{p}{B_i} \times 100 \quad (\text{Eq. 1})$$

Where, p is the amount of extracted pectin (0.38 g), and Bi is the initial amount of apple pomace (5 g).

Characterization of the resulting pectin included determination of equivalent weight (EW), methoxyl content (MeO), total anhydrouronic acid content (AUA), and degree of esterification (DE) (Khamsucharit *et al.*, 2017). Pectin (0.1 g), ethanol (1 mL), sodium chloride (0.2 g) and carbon dioxide-free distilled water (20 mL) were dissolved and titrated against standard 0.01M NaOH until the mixture adjusted to pH 7.5-8.0. The pH values were determined using an ANION-4100 pH meter containing a glass electrode. The volume of NaOH consumed ( $V_1$ , mL) was used for determination of equivalent weight (EW), using the equation (Eq. 2).

$$EW \text{ (g mol}^{-1}\text{)} = \frac{Wt \times 1000}{V_1 \times N} \quad (\text{Eq. 2})$$

Where, Wt is weight of pectin (0.1 g),  $V_1$  is the volume of NaOH consumed for titration (20.6 mL) of free acid groups, and N is normality of NaOH (0.01 M).

The neutral solution was collected after determination of equivalent weight, and 10 mL of sodium hydroxide (0.01 M) was added. The mixed solution was stirred thoroughly and kept at room temperature for 30 min, after which 10 mL of 0.01 M hydrochloric acid was added and titrated against 0.01 M NaOH to the same endpoint as in the previous equivalent weight titration.

Methoxyl content (MeO) was calculated using the following equation (Eq. 3).

$$\text{MeO}(\%) = \frac{V_2 \times N \times 31}{Wt \times 1000} \times 100 \quad (\text{Eq. 3})$$

Where,  $V_2$  is volume of NaOH consumed for titration (9.5 mL) of de-esterified acid groups, Wt is weight of pectin (0.1 g), N is normality of NaOH (0.01 M), and 31 is the molecular weight of the methoxyl group.

Total anhydrouronic acid content (AUA) of pectin was obtained using the equation (Eq. 4).

$$\text{AUA}(\%) = \frac{176 \times 0.01 \times (V_1 + V_2) \times 100}{Wt \times 1000} \quad (\text{Eq. 4})$$

Where, 176 is the molecular weight of 1 unit of the polygalacturonic acid,  $V_1$  (20.6 mL) is the volume of NaOH from equivalent weight determination,  $V_2$  (9.5 mL) is the volume of NaOH

from methoxyl content determination, and Wt is the weight of the sample (0.1 g).

The degree of esterification (DE) of pectin was measured on the basis methoxyl and AUA content and was calculated using the following equation (Eq. 5).

$$\text{DE}(\%) = \frac{176 \times \text{MeO}}{31 \times \text{AUA}} \times 100 \quad (\text{Eq. 5})$$

Where, MeO is methoxyl content (%), AUA is anhydrouronic acid content (%), 176 is the molecular weight of 1 unit of the polygalacturonic acid, and 31 is the molecular weight of the methoxyl group.

### 2.3. Synthesis of Pec/MMT composites

Pec/MMT composites with different pectin content were synthesized as follows. Pectin (0.05, 0.11 and 0.25 g) was dissolved in water (35 mL) at 60 °C and then added to a well-dispersed MMT suspension obtained by the intensive magnetic stirring of 1 g clay in 15 mL of water. Pec:MMT weight ratios were 1:19, 1:9, and 1:4. The mixtures were stirred continuously at ambient temperature for 2 h. Then, the composites were precipitated with ethanol and dried in a weak vacuum at 60°C.

### 2.4. Characterization of Pec/MMT composites

Thermogravimetric analysis (TGA) of samples was carried out in a nitrogen atmosphere at a temperature of 30 to 1000 °C, using a Labsys Evo analyzer from Setaram (France) at a heating rate of 10 °C per minute.

X-ray diffraction (XRD) patterns were obtained on a DRON-4-0.7 diffractometer from Bourevestnik (Russia), with a Co Ka radiation at a wavelength of 0.179 nm. XRD mounts for each sample were prepared by pipetting a small amount of a water-dispersed sample onto an XRD slide and drying in ambient air at room temperature for 3 h. To ensure the comparability of the XRD measurements of the various samples, the XRD mounts were dried at the same temperature and during the same period for all samples, with the XRD measurements taken shortly afterward.

IR spectra were obtained using a Nicolet iS5 from Thermo Scientific (USA), with a resolution of 3  $\text{cm}^{-1}$  in the 4000–350  $\text{cm}^{-1}$  region. Pellets for infrared analysis were obtained by grinding a mixture of 1 mg sample with 100 mg dry KBr, followed by pressing the mixture into a mold.

Morphology and structure of MMT and Pec/MMT composites were studied using a

scanning electron microscope, JEOL JSM-6610 LV (Japan).

## 2.5. Evaluation of sorption properties

The sorption properties of the composites were studied using the following procedure: 10 mL of water were added to 0.1 g of the sorbent and mixed until a homogeneous suspension had been formed. The mixture obtained was thermostated at 36 °C in a water bath. A 10 mL hydrochloric acid solution (0.01 N) was added to 20 mL acetylsalicylic acid solution (0.53 g L<sup>-1</sup>). The resulting ASA solution with a pH of 2.0 was heated to 36 °C and added over a stirred sorbent suspension. Adsorption was carried out for 30 minutes under static conditions. Then an aliquot of the supernatant solution (10 mL) was diluted in 20 mL of ethanol and analyzed using an SF-2000 spectrophotometer (OKB Spectr, Russia), at a 275 nm wavelength (Popova *et al.*, 2016). The amount of ASA adsorbed was determined by change in concentration of supernatant solution before and after sorption.

## 2.6. Histological studies

The protective effect of Pec/MMT composites against aspirin-induced damage to the small intestine was studied in albino Wistar rats (SPF category). The studies were approved by Local Ethical Committee, S Asfendiyarov Kazakh National Medical University, Registrations No 3, and 4. In this study, 50 albino rats (220±10 g) were equally divided into five groups. Oral delivery of acetylsalicylic acid (20 mg) and sorbents (6.3 mg) was performed daily for 16 days. The control group of rats was kept in equivalent laboratory conditions and received the same diet as the experimental animals. Histological studies were carried out on small intestine tissue samples, which were fixed in 10% neutral formaldehyde and routinely processed (Korzhevsky & Gilyarov, 2010). Approximately 5µm thick serial sections were cut and stained with hematoxylin and eosin (H&E). The photos were recorded through an Axiostar plus microscope from Carl Zeiss (Germany).

# 3. RESULTS AND DISCUSSION

## 3.1. Characterization of pectin

The yield of pectin extracted from the ripe Golden Delicious apple pomace was found to be 7.6%, which is consistent with data from prior studies (Perussello *et al.*, 2017). The equivalent weight (EW), methoxyl content (MeO), total anhydrouronic acid content (AUA), and degree of

esterification (DE) of the resulting sample of pectin were found to be 485.4 g mol<sup>-1</sup>, 2.9%, 53.0%, and 31.1%, respectively. These values are comparable with parameters of apple peel pectin (EW = 652.5 g mol<sup>-1</sup>, MeO = 3.7%, AUA = 62.8% and DE = 33.4%), as previously reported (Virk and Sogi, 2004).

## 3.2. Characterization of Pec/MMT composites

Pectin extracted from apple pomace was used for the preparation of Pec/MMT composites. The composites were obtained by adsorption of the polysaccharide onto a clay mineral (Pec:MMT weight ratios were 1:19, 1:9 and 1:4), followed by precipitation of the composites with ethanol, filtration and drying. The treatment with ethanol promotes the aggregation of well-dispersed polymer-inorganic composites and greatly facilitates the filtration process. The filtrate was clear, and visible traces of pectin molecules and MMT particles were not observed.

According to previous results (Talgatov *et al.*, 2019), the mixing of commercial pectin solution and natural montmorillonite suspension led to quantity adsorption of the polysaccharide on clay mineral (more than 90%). Therefore, taking into account the treatment with ethanol, the content of pectin in the Pec/MMT composites may be assumed to be 5, 10 and 20 wt.%.

To confirm this, the composites obtained, with Pec:MMT weight ratios of 1:9 and 1:4, were studied using thermogravimetric analysis (Figure 1).

**Figure 1.** TGA of pectin (a), MMT (b) and Pec/MMT composites (c, d)

Figure 1 shows the weight loss curves of MMT, pectin, and Pec/MMT composites, which demonstrate multiphase degradation behaviors.

The thermal degradation of pectin occurred in two stages. Below 200 °C, there is an initial weight loss of 10.3%, which corresponds with the evaporation of bound water in the hydrophilic polymer and the removal of other small molecules (Ahn *et al.*, 2017). The principal weight loss (50.4%) occurs in the range from 200 to 500 °C, corresponding to the decomposition of the polymer. The residual weight of pectin at 500 °C was 39.3%. This result is not far from previously reported values (Ahn *et al.*, 2017; Minhas *et al.*, 2018), where the residual weight of commercial pectin samples was around 32-34% at 500°C. MMT also shows two stages of thermal degradation. The first stage observed below 200 °C, with a weight loss of 7.1%, was related to the evaporation of water molecules adsorbed in pores and between the silicate layers (Alshabanat *et al.*, 2013). The second thermal degradation stage of MMT, observed in the range from 500 to 750 °C, with weight loss 5.1%, can be explained by the elimination of the –OH group from the [AlO<sub>6</sub>] octahedral sheet of MMT (Yi *et al.*, 2017). These dehydration stages are observed for both Pec/MMT samples. The significant difference between the thermogram of the unmodified MMT and that of the Pec/MMT composites is that the organic constituent in the composites decomposes in the range from 200 to 500 °C (Al-Shemmar *et al.*, 2013). The weight loss in this range was found to be 7.4% and 11.2 % for composites with Pec:MMT weight ratios of 1:9 and 1:4, respectively. This suggests that the polymer was fixed entirely on the clay, as pectin lost only 50% of its weight in this temperature range.

The purity of pectin extracted from apple pomace and its interaction with MMT was evaluated using FTIR analysis, and the results are shown in Figure 2.

The spectrum of the pectin extracted (Figure 2a) showed a good match with the spectra of commercial pectin (Kumar & Chauhan, 2010; Luo *et al.*, 2019). The characteristic bands at 3432, 2939, 1749, and 1625 cm<sup>-1</sup> correspond to the stretching vibrations of –OH, –CH, C=O of ester, and C=O of acid groups in the pectin molecule, respectively (Sumathra *et al.*, 2017). The absorbance is lower at 1749 cm<sup>-1</sup> than at 1625 cm<sup>-1</sup>, confirming a low degree of esterification of the pectin. The bands in the wavelength range of 1200-1500 cm<sup>-1</sup> correspond to the stretching and bending vibrations of –C-OH, –C-H and –O-H (Thompson, 2018). The wide band in the area from 950 to 1200 cm<sup>-1</sup> are considered to be the “finger print” region for carbohydrates, because it helps in the identification of major chemical groups (–C-O, C-O-C and C-C) in polysaccharides (Urias-Orona

*et al.*, 2010). The spectrum showed in Figure 2b is typical for MMT (Dankova *et al.*, 2014). The absorption band at 3627 cm<sup>-1</sup> is due to the stretching vibrations of structural OH groups of the MMT. The characteristic bands at 1043, 915, 525 and 471 cm<sup>-1</sup> correspond to the stretching vibrations of Si–O, the bending vibrations of AlAlOH, and the bending vibrations of Al–O–Si and Si–O–Si, respectively. Water in montmorillonite resulted in broadband that peaked at 3429 cm<sup>-1</sup>, corresponding with the H<sub>2</sub>O-stretching vibrations. The shoulder close to 3240 cm<sup>-1</sup> is due to an overtone of the bending vibration of water observed at 1632 cm<sup>-1</sup> (Dankova *et al.*, 2014). The spectrum of the Pec/MMT composite was similar to unmodified MMT (Figure 2c). However, the appearance of bands at 2931, 1745, and 1200-1500 cm<sup>-1</sup> confirmed the presence of pectin. The shifting of the absorption band of the C=O group, compared to the same group in pectin, indicated the interaction of the polysaccharide with montmorillonite. A slight shift of some bands characteristic of Al–O and Si–O was also observed (Table 1).

**Figure 2.** IR spectra of pectin (a), MMT (b) and Pec/MMT composite (c)

The anisometric shape of the initial MMT was observed using scanning electron microscopy. A clay mineral consists of microaggregates with poorly traced boundaries (Figure 3a) (Kasprzhitsky *et al.*, 2013). Modification of MMT with pectin leads to a change in surface morphology (Figure 3b). The surface of the composite is more uniform, perhaps, due to the formation of a polymer film.

The results of the XRD study of MMT and Pec/MMT composites are shown in Table 2. The 001 reflection peaks at  $2\theta = 7.0^\circ$ ,  $7.2^\circ$  and  $7.5^\circ$ , corresponding to the basal spacing of calcium ( $d_{001} = 14.6 \text{ \AA}$ ), magnesium ( $d_{001} = 14.3 \text{ \AA}$ ) and sodium ( $d_{001} = 13.6 \text{ \AA}$ ) forms of montmorillonite, were observed in the unmodified MMT (Fedorenko *et al.*, 2010). The appearance of a new 001 reflection peak at  $2\theta = 6.6\text{--}6.7^\circ$  ( $d_{001} = 15.4\text{--}15.6 \text{ \AA}$ ) detected on the XRD patterns of Pec/MMT composites indicates the intercalation of pectin into the interlayer space of layered silicate (Table 2) (Mittal, 2009). The same results have been reported for MMT modified with commercial pectin, where the polysaccharide contributed to changing the surface and structure properties of the clay mineral, due to coating and intercalation, respectively (Talgatov *et al.*, 2016).

### 3.3. Sorption and swelling properties of Pec/MMT composites

Aspirin is rapidly absorbed from the stomach and upper small intestine, reaching maximum drug concentration in plasma through 15–30 minutes after oral administration (Kanani *et al.*, 2015). Therefore, the sorption process was carried out over 30 minutes in an environment simulating the stomach ( $36^\circ\text{C}$  and  $\text{pH} = 2.0$ ) (Lu *et al.*, 2010). The sorption properties of Pec/MMT composites were evaluated using the residual concentration of ASA in the supernatant, and compared with those of unmodified MMT. Results of ASA sorption on MMT and Pec/MMT composites are presented in Table 3.

According to the analysis of the supernatant solution using spectrophotometry, the sorption capacity of MMT increased from  $3.1 \text{ mg g}^{-1}$  after modification with 5 wt.% of pectin. However, further, increase in pectin content to 20 wt.% led to a decrease in the sorption capacity of the hybrid composites to  $1.0 \text{ mg g}^{-1}$ . The capacity of the sorbents towards ASA was correlated with their swelling ability (Figure 4).

Of note is that the Pec/MMT particles demonstrate an excellent dispersibility in neutral medium and swells only in acidified water.

Improving the swelling ability of hybrid composites occurs probably due to the interaction of pectin macromolecules with cations ( $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Al}^{3+}$ ) released from clay at low pH (Massaro *et al.*, 2018) and cross-linking of Pec/MMT particles (Gawkowska *et al.*, 2018) with the formation of gel-like structure. This is of interest because polysaccharide hydrogels are considered as an alternative to other gastroprotective drugs (Bor *et al.*, 2019).

**Figure 4.** Swelling of MMT and Pec/MMT composites in acidified water

### 3.4. Protective properties of Pec/MMT composites

The protective effect of the hybrid composites obtained was evaluated by observing changes in the morphological characteristics of the small intestine of the rats (3 groups), which were administered ASA (20 mg) with Pec/MMT composites (6.3 mg), in comparison with those of control rats and group of rats taking only ASA. A high dose of aspirin ( $90 \text{ mg kg}^{-1} \text{ d}^{-1}$ ) was taken to cause GI adverse events. The results of the histological studies are presented in Figure 5.

The photomicrograph of the small intestine of control rats showed a normal histological structure (Figure 5a). Oral administration of a high dose of ASA to rats for 16 days led to acute small intestinal mucosal injury, corresponding to the development of enterocolitis in test animals (Figure 5b). The mucosal injury scores of groups taking aspirin with Pec/MMT composites (Figure 5c,d,e) were decreased compared with those of rats taking only ASA (Figure 5b). Maximum protective effect demonstrated the composite with a 20 wt.% pectin content. In this case, a normal histological structure of the intestinal mucosa with minor areas of swelling and dystrophy of the parenchyma of the glands was observed (Figure 5e). ASA adsorption on Pec/MMT insufficiently

contributes to the protection of the gastrointestinal tract (Table 3). Therefore, improvement of the protective properties of Pec/MMT composites by increasing the polymer content can be explained by the biological activity of pectin, leading to wound healing (Minzanova *et al.*, 2018). The effect of polymer content on mucoadhesive properties of hybrid composite is also possible (Sharma *et al.*, 2018).

#### 4. CONCLUSIONS:

This paper presents a simple and effective method for the synthesis of Pec/MMT composites with a given biopolymer content. According to data derived from physical and chemical studies, the polysaccharide not only coated the surface of MMT, but was also intercalated into the interlayer space of the natural clay mineral.

The resulting Pec/MMT composites showed insufficient sorption capacity towards ASA molecules (1.0-6.8 mg g<sup>-1</sup>) to protect the gastrointestinal tract. However, regeneration of the small intestine of the experimental rats, which were administered high doses of aspirin along with the composites for 16 days, was observed. Optimal normalization of the morphological parameters of the small intestine was observed in rats treated with the Pec/MMT composite containing 20wt.% pectin. The protective properties of the composites were improved by increasing the pectin content, probably due to the biological activity of the polysaccharide.

It should be noted that the composites swelled in acidified water (pH = 2.0), and their swelling ability was higher to compare with unmodified MMT. This can be caused by the cross-linking of Pec/MMT particles due to the interaction of pectin with cations released from the clay, apparently requiring a separate investigation.

#### 5. ACKNOWLEDGEMENTS:

The study was funded by the Committee of Science of the Ministry of Education and Science of the Republic of Kazakhstan (grants AP05133114 and AP05131542). The authors are grateful to S. Bakhtiyarova and B. Zhaksymov for their assistance.

## ABSTRACT

O petróleo e seus derivados afetam adversamente a biodiversidade dos microorganismos e a função do solo. Em solos contaminados com óleo, desenvolvem-se comunidades bacterianas únicas, adaptadas à poluição. Neste trabalho, a estrutura bacteriana e a diversidade da comunidade microbiana foram estudadas em amostras de solos contaminados com óleo nos depósitos do Cazaquistão usando o sequenciador Illumina MiSeq. Os resultados do estudo mostraram que os representantes dos seguintes filos bacterianos dominaram nas amostras de solo selecionadas: Proteobactérias, predominantes em solos contaminados com óleo (até 48%), Actinobactérias (até 29,33%), Firmicutes (até 25,74%), Bacteroidetes (até 33,28%). Os representantes dos filos de Planctomycetes, Verrucomicrobia, Chloroflexi (0,76% -4,62%) foram encontrados em menor quantidade. Todos os solos não contaminados foram dominados pelas famílias Micrococcaceae, Flexibacteraceae, Sphingomonadaceae, Planococcaceae, Flavobacteriaceae, contaminados pelas famílias Halomonadaceae, Flavobacteriaceae, Alteromonadaceae, Dietziaceae, Pseudomonadaceae, Bacillaceae, Peptomonadaceae, Bacillaceae. No nível de gênero, amostras de solos não contaminados e contaminados também demonstraram diversidade significativa. Os gêneros bacterianos dominantes nas amostras do solo não contaminado foram Hymenobacter, Arthrobacter, Gillisia. Em solos contaminados de três depósitos, os microrganismos dos gêneros Halomonas, Marinobacter, Pseudomonas (principalmente em amostras de solo 2KO), Bellilinea e Mycobacterium (principalmente amostra Md) se espalharam mais amplamente; e uma população muito grande de microrganismos do gênero Halomonas foi encontrada na amostra de solo contaminado da região de Atyrau. Uma comparação da estrutura taxonômica das comunidades microbianas de solos contaminados com óleo indica que a composição da população microbiana muda dependendo do grau de poluição por óleo. Amostras de solos não contaminados foram caracterizadas por maior diversidade bacteriana do que amostras de solos contaminados. Os microrganismos pertencentes aos filos dominantes foram principalmente associados à decomposição de hidrocarbonetos oleosos. A caracterização das comunidades bacterianas que vivem nos solos contaminados e a avaliação de sua capacidade de decompor o óleo podem ser potencialmente um guia para a biorremediação de solos contaminados.

## ABSTRACT

Oil and oil products adversely affect both the biodiversity of the microorganisms and the soil function. In oil-contaminated soils, unique bacterial communities develop that are adapted to pollution. In this work, the bacterial structure and diversity of the microbial community have been studied in samples of oil-contaminated soils in Kazakhstan deposits using the Illumina MiSeq sequencer. The results of the study showed that the representatives of the following bacterial phyla dominated in the selected soil samples: Proteobacteria, prevailing in oil-contaminated soils (up to 48%), Actinobacteria (up to 29.33%), Firmicutes (up to 25.74%), Bacteroidetes (up to 33.28 %). The representatives of Planctomycetes, Verrucomicrobia, Chloroflexi (0.76% -4.62%) phyla were found in smaller amounts. All the uncontaminated soils were dominated by Micrococcaceae, Flexibacteraceae, Sphingomonadaceae, Planococcaceae, Flavobacteriaceae families, contaminated ones – by Halomonadaceae, Flavobacteriaceae, Alteromonadaceae, Dietziaceae, Pseudomonadaceae, Bacillaceae, Xanthomonadaceae, Anaerolinaceae, Mycobacteriaceae and Peptococcaceae families. At the genus level, samples of uncontaminated

and contaminated soils also demonstrated significant diversity. The dominant bacterial genera in the samples of the uncontaminated soil were *Hymenobacter*, *Arthrobacter*, *Gillisia*. In contaminated soils of three deposits the microorganisms of the *Halomonas*, *Marinobacter*, *Pseudomonas* (mostly in 2KO soil sample), *Bellilinea* and *Mycobacterium* (mostly Md sample) genera were spread more widely; and a very large population of the microorganisms of the *Halomonas* genus was found in the contaminated soil sample from the Atyrau region. A comparison of the taxonomic structure of microbial communities of oil-contaminated soils indicates that the composition of the microbial population changes depending on the degree of oil pollution. Samples of uncontaminated background soils were characterized by higher bacterial diversity than samples of contaminated soils. The microorganisms belonging to the dominant phyla were mostly associated with the decomposition of oil hydrocarbons. The characterization of the bacterial communities living in the contaminated soils and the assessment of their ability to decompose oil can potentially be a guide for bioremediation of contaminated soils.

## АННОТАЦИЯ

Нефть и нефтепродукты отрицательно влияют как на биоразнообразие микроорганизмов, так и на функцию почвы. В нефтезагрязненных почвах развиваются уникальные бактериальные сообщества, адаптированные к загрязнению. В данной работе исследована бактериальная структура и разнообразие микробного сообщества в образцах нефтезагрязненных почв месторождений Казахстана методом секвенирования основанного на технологии Illumina с использованием прибора MiSeq. Результаты исследований показали, что в отобранных образцах почв доминировали представители типов: *Proteobacteria*, преобладающие в загрязненных нефтью почвах (до 48%), *Actinobacteria* (до 29,33%), *Firmicutes* (до 25,74%), *Bacteroidetes* (до 33,28%). В меньшем количестве были обнаружены типы *Planctomycetes*, *Verrucomicrobia*, *Chloroflexi* (0,76%-4,62%). Изучение микробоценоза на уровне семейства и рода показало, что в не загрязненных почвах доминировали семейства *Micrococcaceae*, *Flexibacteraceae*, *Sphingomonadaceae*, *Planococcaceae*, *Flavobacteriaceae*, в загрязненных же почвах - *Halomonadaceae*, *Flavobacteriaceae*, *Alteromonadaceae*, *Dietziaceae*, *Pseudomonadaceae*, *Bacillaceae*, *Xanthomonadaceae*, *Anaerolinaceae*, *Mycobacteriaceae* и *Peptococcaceae*. На уровне рода в образцах незагрязненной и загрязненной почв разнообразие значительно отличалось. Доминантными родами в образцах чистой почвы были представители *Hymenobacter*, *Arthrobacter*, *Gillisia*. В загрязненных почвах трех месторождений более широкое распространение в образце почвы 2КО получили микроорганизмы родов: *Halomonas*, *Marinobacter*, *Pseudomonas*; в образце Md: *Bellilinea*, *Mycobacterium* и в образце At - *Halomonas*. Сравнение таксономической структуры микробных сообществ нефтезагрязненных почв указывает на то, что в зависимости от степени загрязнения нефтью изменяется состав микробной популяции. Более высокое бактериальное разнообразие наблюдалось в незагрязненных фоновых почвах по сравнению с загрязненными образцами. Микроорганизмы, относящиеся к доминирующим типам, связаны в большинстве своем с разложением углеводородов нефти. Характеристика бактериальных сообществ, живущих в загрязненных нефтью почвах, и оценка их способности разлагать нефть могут потенциально служить ориентиром для биоремедиации загрязненных сред.

## 1. INTRODUCTION:

Oil is the most valuable raw material, without which modern civilization is impossible. However, the processes of its development, transportation, storage, and processing very often become the sources of environmental contamination and acquire a catastrophic scale. The share of hydrocarbon fuel is 2/3 of the world's energy consumption. The existing demand for oil and oil products annually increases on average by 8 %, and production — by 5.5 % (Diarov *et al.*, 2006). The increasing contamination of the environment with oil and oil products leads to severe disruption in the natural ecosystems, biological balance, and biodiversity. The studies showed that soil properties, such as pH, the

presence of water, air, and nutrients, the redox potential, the presence of organic substances affected the structure of bacterial communities (Wakelin *et al.*, 2008). The abundance and diversity of the microbial communities are indicators of soil quality (Mathew *et al.*, 2012).

Thus, the problem of soil contamination with oil poses a serious environmental threat to the environment and leads to disruption in the ecological balance, to degradation, and even to the desertification of these territories. Emergency oil spills often lead to the formation of technogeneous deserts, where the process of self-healing lasts for 10 – 25 years (Parkhomenko, Soprunova, 2008; Polyanskaya, Zvyagintsev, 2005). The oil biodegradation management should be, first of all, aimed at activating microbial

communities and creating the optimal conditions for their existence. In this regard, studying the microbial complexes in the contaminated soils is of scientific and practical interest.

In Kazakhstan, oil production is concentrated in the Caspian region, in the Atyrau and Mangistau regions, and in the south in the Kyzylorda region. The climate in these regions is sharply continental and arid. The soils are characterized as highly saline gray-brown soils, salt marches, and solonchaks. The development of oilfields leads to contamination of large areas and creates environmental problems that pose a threat to public safety.

Today, in terms of proven oil reserves, Kazakhstan is among the 15 leading countries in the world, with 3% of the world's oil reserves. Oil and gas regions occupy 62% of the country's area and have 172 oilfields, of which more than 80 are under development. More than 90% of oil reserves are concentrated in the 15 largest fields - Kumkol, Tengiz, Kashagan, Karachaganak, Uzen, Zhetybai, Zhanazhol, Kalamkas, Kenkiyak, Karazhanbas, Northern Buzachi, Alibekmola, Central and Eastern Prorva, Kenbai, Korolevskoye. Deposits are located in six of the 14 regions of Kazakhstan. These are Aktobe, Atyrau, West Kazakhstan, Karaganda, Kyzylorda, and Mangystau regions. At the same time, approximately 70% of hydrocarbon reserves are concentrated in the west of Kazakhstan. It should be noted that the Aktas deposit (Mangistau region) and the Zhanatalap deposit (Atyrau region) are not the largest oil and gas deposits.

The Atyrau region possesses the most explored oil reserves. On its territory, more than 75 oilfields with industrial reserves of 930 mln t are discovered. The largest oilfield in the region is Tengiz (initial recoverable reserves are 781.1 mln t). The region ranks first in oil production in the Republic. The Zhanatalap oil and gas deposit was discovered in 1968 and is located in the Isataevsky district of the Atyrau region, 85 km west of Atyrau. The field is located in a very dry, hot, agroclimatic area. The climate is sharply continental, arid, with manifested large annual and daily amplitudes of air temperatures. Low-sulfur oil constitutes 0.12-0.38%, low-paraffin oil – 1.31-1.01%. The operating mode of the reservoir is water driven. Oilfield water contains calcium chloride, has a density of 1,177-1,184 kg/m<sup>3</sup> and mineralization of 277.4-289.2 g/l.

Kumkol is an oil and gas deposit in the Kyzylorda region of Kazakhstan. The total area of the Kumkol field is 23,143 ha. This field referred to

the Turanian oil and gas province and was discovered in February 1984. Kumkol is located 150-170 km north of the city of Kyzylorda. Hydrocarbon deposits are located at a depth of 0.9 - 1.4 km. The initial flow rate of the wells is 20 - 130 t/day. The density of oil is 0.81-0.83 g/cm<sup>3</sup>, the sulfur content is 0.11 - 0.52%, paraffins constitute 10.8-15.5%, asphaltenes content ranges from 0.11-0.92% to 5.7%, resins content – from 4.8% to 19.8%. Recoverable oil reserves at Kumkol field amount to 130 mln t; that of gas – to 15 bln m<sup>3</sup> (Bulekbaev *et al.*, 1996).

In the Mangistau region, over 70 fields have been discovered with recoverable oil reserves of 725 mln t, as well as reserves of condensate equaling to 5.6 mln t. Less than half of the fields are in operation. Most of them are in the late stages of development. The vast majority of residual reserves are classified as hard to recover. The largest deposits are Aktas, Uzen, Zhetybai, Kalamkas, Karazhanbas. The Aktas oil and gas condensate field is located in the Mangistau region, 85 km southeast of Aktau. The oils of productive horizons are heavy (horizons IV, X, XI) and very heavy (horizon III), with a density of 0.87-0.915 g/cm<sup>3</sup>, low content of sulfur (0.2%) and high content of paraffin (20% to 26.14%). The asphaltenes content varies from 2.33 to 5.6%, and silica gel resins content is within the range of 4.54 - 6.8% (Portnov, Petrov, Talerchik, 2015).

The research methods based on microbial cultivation does not provide complete comprehensive knowledge of the microbial community since most microorganisms do not grow on conventional culture media, and researchers deal only with a small fraction of the real soil microbiota (Wolińska, 2019). The widespread use of the molecular methods in studying the ecology of the microorganisms in the contaminated areas provides extraordinary opportunities for new bioremediation strategies. With the introduction of the new-generation sequencing methods in molecular ecology, it has become possible to increase the number of identified types of microorganisms (Ma *et al.*, 2015; Chakraborty *et al.*, 2014).

To comprehensively assess the potential of biodegradation in the contaminated area and the changes in the structure and functional activity of the microbial communities involved in bioremediation, we used the Illumina MiSeq method of high-throughput sequencing. This allowed obtaining a more comprehensive and updated vision of the microbial community in the studied samples.

The present work was aimed at studying the bacterial composition of the contaminated soils in the oilfields of Kazakhstan, compared to the uncontaminated soils, for understanding the dynamics of the bacterial community development using the new generation high-throughput sequencing.

## 2. MATERIALS AND METHODS:

### 2.1. Experimental site

Six soil samples from three regions of Kazakhstan were selected in sterile plastic containers for the analyses according to state standards 17.4.4.02-2017 (GOST 17.4.4.02-2017, 2017). Soil samples were taken sterile layer by layer from the depth of 0-5 and 5-20 cm by the envelope method. Each combined sample consisted of three-point samples weighing from 200 to 250 g of soil each. Samples were taken under aseptic conditions: they were taken with a sterile metal spatula and placed in sterile plastic containers. Then the samples were packed to the cooler bags at 4 °C and immediately delivered to the laboratory.

Two samples were taken from the Atyrau region, the Zhanatalap oilfield: sample **At** — contaminated with oil, sample **PI2** — from the clean area (following the WGS84 system): latitude: 44° 51' 10" N (44.8528), longitude: 65° 30' 33" E (65.5092). Two samples were taken from the Kyzylorda region, the **Kumkol** oilfield: **1KO** — uncontaminated, **2KO** — from the contaminated area (WGS84): latitude: 44° 51' 10" N (44.8528), longitude: 65° 30' 33" E (65.5092). Two samples were taken from the Mangistau region, the Aktas oilfield: **MCI** — uncontaminated, **Md** — from the contaminated area (WGS84): latitude: 43° 39' 0" N (43.65), longitude: 51° 12' 0" E (51.2).

In the area of each oilfield, soil samples were taken at various distances from the oil production zone. Directly from the oilfield, a sample was taken for obtaining soil with a high degree of contamination, and for control (clean, uncontaminated soil, background), a sample was taken from the territory of a settlement 7 km away from oil production. The soil samples were taken from the depth of 20 cm using the method of sampling from five points in three repetitions. One part of the soil was combined in a sterile bag and delivered to the laboratory with a refrigerant for studying the bacterial diversity. The other part was used for determining the oil content. Prior to the analysis, the delivered soil samples had been stored at -20°C. Before the analysis, all samples

had passed through a 2 mm sterile sieve for removing large particles and foreign objects.

### 2.2. Determination of oil content in the soil samples

The quantitative content of oil in the soil was determined by the gravimetric method (Lurie, 1984). For this purpose, 10 g weighed samples of the soil were made. They were put into funnels with filtering paper and poured with chloroform until the extract became colorless. The chloroform oil extract was collected into tared vials and naturally evaporated in a fume hood for 24 hours. The residue was weighed on an Explorer analytical weigher (Ohaus, USA). For each soil sample, three weighed samples were made.

### 2.3. Parameters of the oil from the Kumkol, Zhanatalap, and Aktas oilfields

The specific weight of the oil from the Zhanatalap oilfield was 0.87 g/cm<sup>3</sup>, the density at 20°C was 0.8437 g/cm<sup>3</sup>, the viscosity at 0 °C was 36.4 - Pa · c. The content of paraffin was 1.31 – 1.01 %, of sulfur — 0.12 %, of asphaltenes — 0.02 %, of silica gel resins — 5.62 %, and of sulfate resins — 6 %. The oilfield water was calcium-chloride with a density of 1,177 – 1,184 kg/m<sup>3</sup> and the mineralization of 277.4 – 289.2 g/l. The oil in the productive horizons of the Aktas oilfield was viscous, with a density of 0.87 – 0.91 g/cm<sup>3</sup>; it was low-sulfur (0.2 %), and high-paraffin (20 – 26.14 %). The content of asphaltenes was 2.33 – 5.6 %, and of silica gel resins — 4.54 to 6.8 %. The Kumkol oil was low-viscosity and low-sulfur, relatively light (0.81 – 0.83 g/cm<sup>3</sup>), contained many light fractions, and was distinguished by the absence of harmful impurities. The content of paraffin was 15 %, of sulfur — 0.27 %, of asphaltenes — 5.4 %, and of silica gel resins — 19.2 %. The mineralization of water (calcium chloride) in the horizons was 49.7 – 84 g/l (Nadirov, 1995).

### 2.4. Parameters of the soils in the oilfields

The soils of the Kumkol deposit are characterized as gray-brown desert sandy-clay soils, the soils of Aktas deposit of the Mangystau region are gray-brown solonchak soils, and the soils of Zhanatalap deposit of the Atyrau region are coastal meadow solonchak soils. The amount of humus in the upper soil horizon of Kumkol deposit is 0.9%, of Zhanatalap deposit -1.7%, of Aktas deposit - 1.1%. The soils of all deposits are characterized by a sulfate-chloride type of salinization. The establishment of a taxonomic affiliation (type, subtype, genus) of soils was carried out by the employees of the U.U. Uspanov

Kazakh Research Institute of Soil Science and Agrochemistry in accordance with the methods (Gavrilyuk, 1959) and the regulatory requirements approved for Kazakhstan (Scientific and methodological guidelines for monitoring the land of the Republic of Kazakhstan, 1994). The research was based on the comparative geographical method, which consisted of comparing some soils with others taking into account the conditions of soil formation. A method of obtaining the actual material was field soil studies with subsequent processing and generalization of the results of laboratory chemical analysis of the selected samples.

At the stage of conducting field studies, morphological methods were used (Rozanov, 2004), which ensured the reliability and validity of field soil diagnostics and characteristics of the main morphological properties of soils. The location of the soil section for the characterization of background soils was selected, taking into account the most typical natural conditions. Field soil studies included the laying of soil sections, then their description was made, and soil samples were taken. The location of the soil section for the characterization of background soils was selected, taking into account the most typical natural conditions. The depth of soil sections was determined by the depth of soil formation processes.

The description of the soil section included:

- location and number;
- characteristics of the terrain and underlying rocks;
- the position of the section relative to the macro-, meso- and microrelief;
- the depth of boiling, the form of carbonate emissions;
- characteristics of the soil surface;
- description of genetic horizons.

The selection and description of genetic horizons were carried out according to the following morphological indicators (Gavrilyuk, 1959; Rozanov, 2004):

- horizon thickness;
- color and character of coloring;
- moisturizing;
- structure;
- mechanical composition;
- density;

- porosity;
- allocation of water-soluble salts and other newly formed soil structures;
- the presence and type of inclusions;
- development of the root system of plants;
- the nature of the transition of one horizon to another.

Samples for analysis were taken at the most typical sections characterizing the soil cover of the territory to establish the basic chemical and physicochemical properties of soils. Sampling was carried out over genetic horizons, in a 10-cm layer in their center.

The taxonomic determination of the soil was made on the basis of the description of the soil sections in accordance with the generally accepted classification (Egorov, Ivanova, Friland, 1977) and the systematic list of soils previously developed for the study area (Soils of the Kazakh SSR: Guryev region, 1970; Soils of the Kazakh SSR: Soils of the Kyzylorda region, 1983).

The involvement of regional classifications was due to the fact that they were developed according to the results of extensive systematic soil studies of Kazakhstan; monographs were published for each region, accompanied by soil maps with the 1:300,000 scale where soil diagnostic indicators (morphological and chemical) were determined (Soils of the Kazakh SSR: Guryev region, 1970; Soils of the Kazakh SSR: Soils of the Kyzylorda region, 1983).

To obtain the actual material, field soil studies were carried out with subsequent processing and generalization of the results of laboratory chemical analysis of the selected samples. Organic matter (humus) was determined by the method of Tyurin. The method is based on the oxidation of organic matter by a solution of potassium dichromate in sulfuric acid and the subsequent determination of trivalent chromium equivalent to the content of organic matter. To assess soil salinization, anions ( $\text{CO}_3^{2-}$ ;  $\text{HCO}_3^-$ ;  $\text{Cl}^-$ ;  $\text{SO}_4^{2-}$ ) and cations ( $\text{Ca}^{2+}$ ;  $\text{Mg}^{2+}$ ;  $\text{Na}^+$ ;  $\text{K}^+$ ) of highly soluble salts were determined. The degree of soil salinization was estimated by the total content of highly soluble salts in the water extract of the soil (GOST 26213-91, 1991). It is known that saline soils include soils in which the concentration of highly soluble salts in soil solutions exceeds 5-7 g/l, i.e., soils containing 0.05-1.15% of highly soluble salts depending on their composition.

## 2.5. DNA isolation, amplification, and sequencing on MiSeq Illumina

Two hundred and fifty milligrams of the obtained soil samples were taken for DNA isolation. The general genomic DNA was isolated using a NucleoSpin® Soil kit (Macherey-Nagel GmbH & Co.KG, Duren, Germany), following the manufacturer's guidelines. The DNA concentration was measured on a Qubit® 2.0 fluorimeter using a Qubit™ds DNA HS Assay Kit (Life Technologies, Oregon, USA).

The genetic libraries were prepared for sequencing following the *16S Metagenomic Sequencing Library Preparation* guide (part no. 15044223 rev. A). Each DNA sample was amplified using the KAPA HiFi Hot Star Ready Mix (KAPA Biosystems, Cape Town, South Africa). The PCR amplification was made in Eppendorf Master ProS thermal cycler (Eppendorf AG, Hamburg, Germany). The V3 and V4 regions of the 16Sr RNA gene were amplified using universal bacterial primers with the addition of the Illumina adapters and contained the following sequences of the nucleotide pairs: 5'-TCGTCGGCAGC GTCAGATGTGTATAAGAGACAGCCTACGGG N GGWGCAG-3' for the forward primer, and 5'-GTCTCGTGGGCTCGGAGATGTGTATAAGAGA CAGGACTACHVGGGTATCTAATCC-3' for the reverse primer (Klindworth *et al.*, 2013).

The reaction mixture consisted of 2.5 µl of the DNA template, 5 µl of each primer in the concentration of 1 µM, and 12.5 µl of KAPA HiFi Hot Start Ready Mix in the 2X concentration. The amplification cycles were performed according to the following program: one cycle at 95 °C for three minutes, followed by 25 amplification cycles at 95 °C for 30 seconds, one cycle at 55 °C for 30 seconds, one cycle at 72 °C for 30 seconds, and one cycle at 72 °C for five minutes. The PCR product was purified using an Agencourt AM Pure PCR purification kit (Beckman Coulter Inc. Beverly, Massachusetts, USA). Nextera XT Index primer adapters (Illumina Inc., San Diego, CA, USA) were added to each sample through the amplification in the reaction mixture containing 12.5 µl of KAPA HiFi Hot Start Ready Mix, 5 µl of each index primer, 10 µl of water, and 5 µl of the PCR product. The amplification program included one cycle at 95 °C for three minutes, followed by eight cycles of amplification at 95 °C for 30 seconds, one cycle at 55 °C for 30 seconds, one cycle at 72 °C for 30 seconds, and one cycle at 72 °C for five minutes. The PCR product with added indices was also purified using an Agencourt AM Pure PCR purification kit (Beckman Coulter Inc. Beverly, Massachusetts, USA).

At each stage of preparing the libraries after the amplification, the concentration and the size of the obtained PCR products were determined through their detection in the agarose gel and on Agilent 2100 bioanalyzer (Waldbronn, Germany) using an Agilent DNA 1000 Kit (Agilent Technologies, Waldbronn, Germany). Each sample was diluted to a concentration of 4 nM and combined into a single pool. The pooled libraries were denatured with NaOH and diluted with the hybridization buffer. The pooled libraries were sequenced on Illumina MiSeq device using a 600-cycle MiSeq® Reagent Kit v3 (Illumina Inc., San Diego, CA, USA), following the manufacturer's recommendations.

## 3. RESULTS AND DISCUSSION:

### 3.1. Oil contents in the soil samples

The analysis showed that the oil content in the contaminated soil from the Kumkol oilfield was 7.5 %, from the Zhanatalap oilfield — 7.3 %, and from the Aktas oilfield — 7.8 %.

### 3.2. The 16S rRNA metagenomic analysis of the soils from the oilfields in Kazakhstan

#### 3.2.1. The changes in the composition of the bacterial communities at the phylum level

Microorganisms in the soil play a key role in various biogeochemical processes, and some functionally significant microbial groups can be especially vulnerable to oil spills (Urakawa *et al.*, 2012; Rodriguez *et al.*, 2015). Petroleum hydrocarbons can directly influence the microorganisms, exerting a toxic effect (especially the polyaromatic ones), or changing the physicochemical properties of the soil (reducing the availability of mineral nutrition elements, deteriorating the water and air conditions, deterioration of the nitrogen regime of soils and a decrease in the content of mobile forms of phosphorus) (Voevodina, Rusanov, Vasilchenko, 2015; Liao, Wang, Huang, 2015). As a result of oil ingress, the total population and the structure of the microbial community change. Its composition and the degree of diversity depend both on the type, concentration, and duration of exposure to the pollutant, and on the type of the soil and the state of the microbiocenosis before the ingress of the pollutant (Kirienko, Imranova, 2015; Liao *et al.*, 2015).

The structure of the microbial community was analyzed in three taxonomic categories — the

phyla, the families, and the genus. The structure of bacteriocenosis at the level of phylotypes allowed characterizing the processes in the contaminated samples. As a result of the studies, in considering the taxonomic structure of the soil microbiomes at the three deposits, the dominance of seven bacterial phyla was detected: *Proteobacteria*, *Actinobacteria*, *Bacteroidetes*, *Firmicutes*, *Planctomycetes*, *Verrucomicrobia*, and *Chloroflexi* (Tables 1, 2). All soil samples were dominated by the *Proteobacteria* (21.22 – 44.48 %), *Actinobacteria* (9.66 – 29.33 %), *Bacteroidetes* (3.9 – 33.28 %), and *Firmicutes* (12.44 – 25.79 %) phyla. These are the phylotypes that almost always dominate both in the contaminated and uncontaminated soils (dos Santos *et al.*, 2011). *Proteobacteria* are the largest group of bacteria that play an important role in the cycles of biogenic elements in nature, and are typical dominants in the contaminated soils, especially at the early stages of hydrocarbon degradation. Numerous studies showed that proteobacteria were the dominant group that decomposed PAHs (Winding, Hund-Rinke, Rutgers, 2005; Wu *et al.*, 2016). The greatest number of the microorganisms of this phylogroup was found in the contaminated soil in the Atyrau (At — 44.48 %) and the Kyzylorda regions (2KO — 42.49 %) (Table 2). Their population was two times higher compared to the soils in the Mangistau region. The results were similar to those of other studies, where the *Proteobacteria* were the dominant type decomposing the PAHs found in the contaminated samples (Dörr de Quadros *et al.*, 2016; Yadav *et al.*, 2015).

The representatives of the *Actinobacteria* phylum were the next prevailing group in the analyzed samples. *Actinobacteria* are widely spread in the soil and water contaminated with oil, and can actively decompose diesel oil, n-alkanes, phenols, and PAHs (Zhang, Mortelmaier, Margesin, 2012).

As a rule, the microorganisms belonging to this phylum are well adapted to the environment with limited resources and do not show significant changes due to contamination with xenobiotics. The *Actinobacteria* phyla prevailed in the soil from the Mangistau region (MCI — 29.33 %, and Md — 23.67 %) (Tables 1, 2). According to some researchers, the *Actinobacteria* perform anaerobic degradation of cyclic and aromatic hydrocarbons at the later stages of oil biodegradation (Pineda-Flores *et al.*, 2004). The next group in terms of the population were the microorganisms that were part of two phyla — *Bacteroidetes*, which prevailed in the soil samples from the Kyzylorda region: 1KO

— 14.78 %, 2KO — 12.20 %, and in the sample of the uncontaminated soil PI 2 (Atyrau region) — 33.28 %, and *Firmicutes*, the largest number of which was found in the contaminated soil from the Atyrau region and amounted to 25.79 % (Table 2). The representatives of these two phyla belong to the common component of the soil microorganisms and are present in all types of soils that are resistant to drying; therefore, in arid climatic conditions, they can maintain their population. As a rule, the bacteria in this group have a wide range of physiological adaptations, which allows them to occupy various ecological niches, while multi-enzyme systems ensure the utilization of various substrates as the sources of carbon and energy (Matishov *et al.*, 2013). The largest number of bacteria of the *Chloroflexi* phylum (Md — 19.42 %) was noted in the contaminated soil from the Aktas oilfield in the Mangistau region. In other soil samples, their content was quite low and ranged from 0.68 % to 0.91 %. The representatives of the *Verrucomicrobia* (3.33 % – 3.88 %) and *Planctomycetes* (0.76 % – 4.62 %) phyla were present in the uncontaminated soils from all three oilfields (Table 1). *Verrucomicrobia* are extremely widespread in nature; they amount to 1 – 10 % of the soil microbiota and have an important ecological value, while the *Planctomycetes* phylum plays an important role in the nitrogen cycle, methanogenesis, and methylotrophy (Fuchsman *et al.*, 2012). The content of other representatives of the phyla in the soil samples amounted to small fractions in the range of 0.26 – 1.05 %. The presence of the microorganisms belonging to the *Euryarchaeota* phylum in the soils from the Zhanatalap oilfield and in the contaminated soil from the Aktas oilfield raised interest. Moreover, the highest content was found in the contaminated soil from the Zhanatalap oilfield (5.56 %); besides, the representatives of the *Synergistetes* phylum were found in the contaminated soil from the Aktas oilfield in the Mangistau region (6.06 %). It is known that the representatives of the *Euryarchaeota* phylum are chemoautotrophic unicell organisms that play a significant role in the carbon and nitrogen cycles, and the *Synergistetes* phylum includes the gram-negative anaerobic microorganisms that are found in the soils from the areas of oil production.

### 3.2.2. The changes in the composition of the bacterial communities at the family level

At the family level, a complex community structure was observed (Fig. 1).

The comparison of the diversity of the families in the uncontaminated and contaminated samples from the three deposits showed that the contaminated soil from the Kumkol oilfield in the Kyzylorda region (2KO) was dominated by the *Halomonadaceae* (9.45 %), *Flavobacteriaceae* (8.94 %), *Alteromonadaceae* (5.37 %), *Dietziaceae* (3.59 %), and *Pseudomonadaceae* (5.04 %) families. The soil from the Aktas oilfield in the Mangistau region (Md) was dominated by the *Xanthomonadaceae* (4.90 %), *Anaerolinaceae* (18.85 %), *Mycobacteriaceae* (8.73 %), *Peptococcaceae* (5.27 %), and *Hydrogenophilaceae* (4.30 %) families. In the contaminated soil of the Zhanatalap oilfield in the Atyrau region (At), the *Halomonadaceae* (21.39 %), *Bacillaceae* (12.73 %), *Halobacteriaceae* (5.55 %), and *Alteromonadaceae* (4.15 %) families were identified.

It should be noted that the contaminated soils from all the oilfields differed in the diversity of the families. All the microorganisms belonging to the families named above were active oil destructors. In our opinion, the difference among the families in all the samples of the contaminated soils could be explained by the different fractional composition of the oils at all three oilfields. For example, the oil from the Aktas oilfield in the Mangistau region was heavy, with the density of 0.872 – 0.915 g/cm<sup>3</sup>; the paraffin content in this oil was high (20 – 26.14 %), while the oil from the Zhanatalap and the Kumkol oilfields was slightly viscous, low-sulfur, and relatively light.

All the uncontaminated soils were dominated by the *Micrococcaceae* (3.41 – 8.21 %), *Flexibacteraceae* (3.07 – 7.52 %), *Sphingomonadaceae* (4.75 – 4.82 %), and *Planococcaceae* (3.24 – 9.77 %) families. The last family was not found in the uncontaminated soil from the Kumkol oilfield; however, other families were found in this sample, such as the *Oxalobacteraceae* (3.72 %), *Isosphaeraceae* (3.58 %), and *Chitinophagaceae* (3.01 %) families. The *Halomonadaceae*, *Flavobacteriaceae*, *Rhodobacteraceae*, and *Verrucomicrobiaceae* families were identified in the uncontaminated soil from the Zhanatalap oilfield in the Atyrau region. The diversity of the families was higher in the uncontaminated background soils, both in terms of the qualitative and the quantitative composition. Most representatives of the *Pseudomonadaceae*, *Micrococcaceae*, *Mycobacteriaceae*, *Halomonadaceae*, *Flavobacteriaceae*, *Dietziaceae*, *Pseudomonadaceae*,

*Rhodobacteraceae*, *Verrucomicrobiaceae*, *Bacillaceae*, and other families are directly involved in oil and petroleum hydrocarbons biodegradation. These families include hydrocarbon-oxidizing bacteria, such as *Arthrobacter*, *Pseudomonas*, *Mycobacterium*, *Rhodococcus*, and others, the species of which are active oil destructors in various soil types (Bogan *et al.*, 2003; Nopcharoenkul, Netsakulnee, Pinyakong, 2013).

### 3.2.3. Changes in the composition of the bacterial communities at the genus level

The diversity of the microbial community at the genus level in the soils of all the oilfields revealed a large share of unclassified microorganisms (13.69 % – 26.87 %). According to the data in Figure 2, the dominant bacterial genera in the samples of the uncontaminated soil were *Hymenobacter* (1KO — 3.63 %), *Arthrobacter* (MCL — 6.43 %), and *Gillisia* (P2I — 16.4 %).

In the contaminated soils from all the oilfields, the microorganisms of the *Halomonas* (2KO — 8.11 %), *Marinobacter* (2KO — 5.26 %), *Bellilinea* (Md — 13.69 %), and *Mycobacterium* (Md — 8.73 %) genera were spread more widely, and a very large population of the microorganisms of the *Halomonas* genus (At — 20.32 %) was found in the contaminated soil from the Atyrau region. The increased content of the microorganisms of the *Halomonas* genus (20.32 % and 8.11 %), which dominated in the contaminated soils from the Atyrau and Kyzylorda regions, could be explained by the fact that the soils of these biotopes were salt marshes and solonchaks with a fairly high level of salinity. The representatives of this genus are characterized by growth in the presence of 5 – 25 % of NaCl.

The soils of the Aktas oilfield in the Mangistau region are dominated by the microorganisms of the *Bellilinea* genus (Md — 13.69 %), which belong to the *Chloroflexi* phylum, and by the representatives of the *Mycobacterium* genus (Md — 8.73 %). These microorganisms are relatively resistant to moisture deficiency and are widely spread in dry soils. They have a rich enzymatic apparatus, which allows mineralization of the poorly soluble organic substances, and are actively involved in the decomposition of nitrogen-containing and nitrogen-free organic substances in the soil. According to S. Y. Zhang, mycobacteria can efficiently decompose tetracyclic and pentacyclic aromatic hydrocarbons (Zhang, Wang, Xie, 2012).

The analysis of the microbial composition showed that at the genus level, the diversity in the samples of the uncontaminated and contaminated soils was significantly different. The microbial community was more diverse in the samples of the uncontaminated soil. It should be noted that there were more unclassified microorganisms in the uncontaminated soils compared to the contaminated soils. In considering the dominant genera in the contaminated samples, it is noteworthy that, along with the presence of the *Halomonas*, *Bellilinea*, *Pseudomonas*, *Marinobacter*, and *Mycobacterium* genera, which are active oil destructors in various soil types, representatives of the *Planomicrobium*, *Agromyces*, *Thiobacillus*, and other genera were also found in the samples.

#### 4. DISCUSSION

Currently, there are many studies available on various bacterial communities and the diversity of the soils contaminated with oil at a different time (Yadav *et al.*, 2015; Abed *et al.*, 2014). The abundance and the diversity of the microbial communities are indicators of soil quality (Mathew *et al.*, 2012; García-Orenes *et al.*, 2013). Oil and oil products disrupt the ecological state of the soil cover and deform the structure of the biocenoses. Therefore, restoring the soil microbial communities is important because they are responsible for the physiological and metabolic processes that are of great importance for soil quality (Rutgers *et al.*, 2016). Changing the species composition of some groups of microorganisms reveals a more definite relationship with the degree and the composition of oil pollution. A high degree of oil pollution may cause complete suppression of the growth and development of microorganisms. Upon the ingress of oil and oil products into the soil, microorganisms are involved in the process of their transformation, which should bring the soil system into equilibrium. The changes in the soil microflora may be used for biomonitoring and bioindication of oil pollution (Kolesnikov *et al.*, 2007).

The metagenomic analysis showed that it was mainly formed by the representatives of seven bacterial phyla: *Proteobacteria*, *Actinobacteria*, *Bacteroidetes*, *Firmicutes*, *Planctomycetes*, *Verrucomicrobia*, and *Chloroflexi*, with *Proteobacteria* and *Actinobacteria* dominating in almost all microbiomes. The microorganisms belonging to the listed dominant types are mostly associated with the decomposition of oil hydrocarbons. An important indicator of soil health

is the *Proteobacteria* phylum, the population of which increases markedly in disturbed soils. In analyzing heterogeneous extremal soil habitats, such as desert soils, permafrost, soils contaminated with oil products and other pollutants, these microorganisms, which, most likely, make up the core or the main part of the soil metagenome, may be detected. The absolute champions among such microorganisms are bacteria of the *Pseudomonas* (*Gammaproteobacteria*), *Arthrobacter* (*Actinobacteria*), *Sphingomonas* (*Alphaproteobacteria*), *Bacillus* (*Firmicutes*), *Rhodococcus* (*Actinobacteria*), *Flavobacterium* (*Bacteroidetes*), and some other genera (Chernov, 2016). All of them are common not only in extremal but also in all other types of soils.

Without enough information, it is difficult to comprehensively understand the structural characteristics of the soil bacterial community and the nature of the changes in its diversity. Therefore, the categories of family and genus were also considered in the analysis of the microbocenosis.

An analysis of the data about the diversity of the families in the contaminated soil from all oilfields showed that they were dominated by the *Halomonadaceae*, *Flavobacteriaceae*, *Alteromonadaceae*, *Pseudomonadaceae*, *Xanthomonadaceae*, *Anaerolinaceae*, *Mycobacteriaceae*, *Halomonadaceae*, *Bacillaceae*, *Halobacteriaceae*, and *Alteromonadaceae* families. All uncontaminated soils were dominated by the *Micrococcaceae*, *Flexibacteraceae*, *Sphingomonadaceae*, *Planococcaceae*, *Oxalobacteraceae*, *Isosphaeraceae*, *Chitinophagaceae*, *Halomonadaceae*, *Flavobacteriaceae*, *Rhodobacteraceae*, and *Verrucomicrobiaceae* families.

The above-listed microorganisms are widespread in the environment. Most representatives of the *Pseudomonadaceae*, *Mycobacteriaceae*, *Halomonadaceae*, *Flavobacteriaceae*, *Dietziaceae*, *Pseudomonadaceae*, *Rhodobacteraceae*, *Verrucomicrobiaceae*, *Bacillaceae*, and other families are directly involved in oil and petroleum hydrocarbons biodegradation. These families include hydrocarbon-oxidizing bacteria, such as *Arthrobacter*, *Pseudomonas*, *Mycobacterium*, *Rhodococcus*, and others, the species of which are active oil destructors in various soil types. Most of them are halotolerant.

As noted earlier, studying the

microbocenosis at the genus level showed a huge number of unidentified microorganisms. The comparative analysis showed that in the uncontaminated soils, the microbial community was more diverse than in the contaminated ones. While the contaminated soils were dominated by the bacteria of the *Halomonas*, *Marinobacter*, *Mycobacterium*, *Bellilinea* genera, in the uncontaminated soils from the oilfields, microorganisms of such genera as *Hymenobacter*, *Arthrobacter*, *Gillisia*, *Salinimicrobium*, *Planomicrobium*, *Planococcus*, and *Halomonas* were found. These data correlate with the studies of Lu Gan *et al.* (2018) and Sutton N.B. *et al.* (2013), who found that the presence of oil pollution had a significant effect on the structure and diversity of the bacterial communities, regardless of the type of the soil matrix. Moreover, it was proven that the uncontaminated soil samples were more diverse than the contaminated ones. Other authors, for example, Mu Peng *et al.* (2015) have shown an inverse correlation, when the microbial diversity is higher in the contaminated soils (Peng, Zi, Wang, 2015). Most likely, these kinds of discrepancies in interpreting the diversity of the microbial coenosis depend on many environmental factors (climatic conditions, soil type, temperature, pH, pollutant concentration).

A change in the population of various groups of microorganisms indicated that the soil microbiota was significantly modified upon contamination with oil hydrocarbons, and various groups of microorganisms reacted differently. The population of some of them increased, the population of some of them decreased, and that of the others remained almost constant. At present, it may be taken as the fact that oil pollution causes changes in the functioning of the soil microbiocenosis. The determination of the bacterial structure and the function in the contaminated soil is the basis for further studies aimed at identifying active bacterial strains in bioremediation.

## 5. CONCLUSIONS:

In this work, it was analyzed the bacterial diversity in the contaminated and uncontaminated soil from three oilfields in Kazakhstan, and it was presented that high bacterial diversity is observed in the uncontaminated background soils.

The characterization of the bacterial communities living in the contaminated soils and the assessment of their ability to decompose oil can potentially be a guide for bioremediation of the contaminated soils. Future studies are required for

choosing the bacterial strains that are active in the degradation of various oil fractions, especially PAHs, which may be used for active management of the bioremediation processes.

**RESUMO**

O artigo é dedicado ao estudo da influência de substâncias biologicamente ativas na regeneração de órgãos internos de mamíferos em estágios iniciais de desenvolvimento. A recuperação completa do órgão após o dano não ocorre. É necessário procurar novas maneiras que revelem os processos que contribuem para a regeneração. O estudo dos processos que ocorrem no corpo antes do nascimento dá a oportunidade de entender os mecanismos do que acontece no período pós-natal nos processos patológicos gerais. Foi estudado o dano mecânico ao fígado em fetos de ratos sob a influência dos biocorretores "Trepel" e "Suvar". Métodos morfológicos, morfométricos, histoquímicos e imuno-histoquímicos foram utilizados para o processamento do material. Os resultados do trabalho indicam que o uso combinado desses biocorretores após o desenvolvimento de um foco de necrose no fígado reduz as manifestações alteradas de hepatócitos, inibe a inflamação reativa ao redor do local da lesão, retarda o recrutamento de fibroblastos para a zona de lesão e inibe a colagenogênese. Ao mesmo tempo, os biocorretores têm um efeito estimulante pronunciado na proliferação de hepatócitos, que, no contexto de atividade enzimática aumentada, se manifesta na forma de ativação da divisão mitótica e poliploidização de hepatócitos. Apesar dos sinais de estimulação regenerativa, como resultado a recuperação completa do fígado no local do tecido morto em ratos experimentais não ocorre; há apenas uma redução de 34,7% no foco da fibrose formada no local do tecido hepático morto, em comparação aos animais de controle.

**ABSTRACT**

The article is devoted to studying the influence of biologically active substances on the regeneration of internal organs in mammals at the early stages of development. Complete recovery of the organ after damage does not occur. It is necessary to look for new ways that reveal the processes that contribute to regeneration. The study of processes that occur in the body before birth allows understanding the mechanisms of what happens in the postnatal period in general pathological processes. It was studied the mechanical damage to the liver in rat fetuses under the influence of biocorrectors "Trepel" and "Suvar." Morphological, morphometric, histochemical, and immunohistochemical methods were used for processing the material. The results of the work indicate that the combined use of these biocorrectors after the development of a necrosis focus in the liver reduces alternative manifestations of hepatocytes, inhibits reactive inflammation around the injury site, slows down the recruitment of fibroblasts to the injury zone, and inhibits collagen genesis. At the same time, biocorrectors have a pronounced stimulating effect on proliferation of hepatocytes, which, against the background of increased enzymatic activity, manifests itself in the form of mitotic division activation and polyploidization of hepatocytes. Despite the signs of regenerative stimulation, as a result, complete recovery of the liver in the site of the dead tissue in experimental rats does not occur; there is only a 34.7% decrease in the focus of fibrosis formed in the place of dead liver tissue, compared to control animals.

## 1. INTRODUCTION:

Mechanical injury hepatic does not show any regenerative progress neither in late perinatal life (Eltschaninov, 2011), nor after birth (Tournier-Thurneyssen, Feldmann, & Bernuau, 1992). The reason for this is those hepatic hepatocytes belong to highly specialized tissue, unable to regenerate through epimorphosis. Although, nowadays, searching for highly efficient means for the pacing of hepatic regeneration is still in progress, apart from the parallel investigation of stem cells (Wang, Zhao, Fish, Logan, & Nusse, 2015).

From (Sigareva, Gerashev, Svyatash, & Lucanina, 2001; Solopaeva & Solopaev, 1991; Sosina, Molotkov, & Reshedko, 1993) it is known that during long decades many attempts have been made to pace hepatic regeneration after various injuries until complete organ recovery was achieved. Forth is the purpose, to activate hepatocyte division, operating (partial hepatectomy) (Andreev, Ostroushko, Laptiyova, & Glukhov, 2018; Berg et al., 2018; Soltys & Zuevkiy, 2000) and pharmacological methods Grevtsov & Belkina, 2002; Sigareva et al., 2001; Sosina et al., 1993) were used in experimental and clinical conditions.

In present days, for veterinary medicine performance improvement (G. I. Ivanov & Grigoryev, 1998), as well as for treatment of different human diseases (Grevtsov & Belkina, 2002; L. N. Ivanov & Kolotilova, 2005; Kolotilova & Ivanov, 2003; Malov, Ivanov, & Kolotilov, 2018; Malov, Ivanov, Kolotilova, & Karpunina, 2018; Vasiliev, Skrebkov, & Pavlova, 1988), zeolites of Alatyrskoe field, Chuvash Republic of Russian Federation are used. "Trepel" is a natural loses sedimentary rock with a silicon base and rich microelement composition (Malov, 2017).

"Suvar" biocorrector is obtained in the laboratory of I.N. Yulianov Chuvash State University and represents natural terpenoids compound with significant microelement content. Technically it is conifer crude turpentine derivative product (Zazhivikhina, 1998). "Suvar" possesses a stimulating effect on human and animal organisms (Frolov, 2003; Petryankin, & Sherne, 1999; Zazhivikhina, 1998). It is proved that the joint application of "Trepel" and "Suvar" favors the development of various mammal organism functional systems, and has immunostimulating and growth promotion effect (Arkhipova, 2008; Sigareva et al., 2001; Tarasov, 2001).

This study aimed to determine the positive influence of the combined application of "Trepel"

and "Suvar" biocorrectors on rats' fetus hepatic regeneration after mechanical injury.

## 2. MATERIALS AND METHODS:

The experiment included 23 pregnant females of outbred rats 257-310 grams of weight. Rat's fetus at the prenatal stage received a mechanical injury of hepatic. Using the innovator method (Chuvash State University named after I.N. Ulyanov Patent RU 2262135, 2005), pregnant female shave undergone an autopsy of the abdominal cavity, in sterile conditions under deep ether-mask anesthesia on the 17th – 19th day of pregnancy.

Uterus, together with a fetus inside, was taken through the operating wound; afterward, along the upper pole, an incision was made. Then a steel stop needle was used (Chuvash State University named after I.N. Ulyanov Patent RU 2262135, 2005), and firstly, membrane rupture was implemented, and later on, the same procedure was made for a well visible fetus (under visual control), in the right hypochondriac region, in hepatic projection point at the depth 0.4-0.5 cm. As are sultofrupturein the hepatic, there appeared stereotypic damage is with dimensions  $3085.7 \pm 368.3 \mu\text{m}^2$ .

At the end of the rapture procedure, the needle was extracted, and the uterus incision was suture closed. After all, fetuses have systematically undergone the same process; the skin was closed with knot silk suture. At the early stages of observation (1<sup>st</sup> and 3<sup>rd</sup> day after the operation), live fetuses were extracted from the uterus employing cesarian operation; later (5 and more days after the operation), female rats independently delivered viable infant rats, which grew and developed according to age. Infant rats got ether-killed in 1, 2, 3, 4, 5, 7, 9, 11, 15, 20, and 30 days after hepatic mechanical injury operation, in the morning from 7.10 to 9 o'clock.

In total, 112 operated fetuses were taken for experiment. The investigation was conducted in accordance with the order of Ministry of Higher and Secondary Education of the USSR dated 13.11.1984 "On the rules of work using experimental animals" (Interstate Council for Standardization, Metrology, and Certification, 2016), and according to Declaration of Helsinki 1975, revision 2000 "On the rules of work using experimental animals." Stillbirth part among infant rats comprised 3% and was not included in analyzed material. Female rats bore an operation satisfactorily and soon afterward were able to pair and get pregnant again.

Rat females from the moment of operation to goether with regular feed started receiving biocorrectors "Trepel" at a dose of 1.25 g/kg and "Suvar" at a dose of 0.05 g/kg of weight. After birth and along with maturity, infant rats, apart from milk feeding, started having common feed containing biologics.

Control was performed on fetuses of the same age (p-78) similarly operated, but the dietary intake did not include biocorrectors.

Obtained material processing included histological staining with hematoxylin, eosin, and cerasine red, as well as histochemical methods. Tetrazolium method (according to Z. Lloyd) was used to determine SDH (succinate dehydrogenase), NADH (nicotinamide adenine dinucleotide, reduced form) and NADPH (nicotinamide adenine dinucleotide, reduced form). Acid phosphatase was defined through method of simultaneous combination with naphthol phosphates AS and permanent salts of diazonium (according to Z. Lloyd). Alkaline phosphatase was determined by Barston method (Lloyd, Gossrau, & Shibler, 1982).

Quantitative assessment of the enzymatic activity of hepatocytes in dynamics was carried out using photometric measurements, conducted in transmitted light on a "Micromed" microscope with a photomodule FMEL-1 and FEU-79 and an output voltage of the amplifier of 1200 V. In order to obtain a monochromatic light beam in the red region of the spectrum passing through the preparation, an interference filter was used with a maximum light transmission at a wavelength of 620 nm. The light transmission was recorded using a Sch-4300 digital voltmeter, after which, by negative decimal logarithm, the light transmission level was transformed into light absorption, which was expressed in units of optical density. According to the law of Lambert-Bouguer-Baer, the optical density of the preparation is proportional to the amount of stain. In turn, the described method meets the requirements of proportionality of stain concentration and enzyme activity. Optical density is calculated as follows:

$$O.D. = LgUi/100.$$

To detect the DNA content in the nuclei of hepatocytes, the Fölgen reaction was performed (hydrolysis in 5N HCL at 20 degrees for 20 minutes, followed by staining with Schiff's reagent for 1 hour at room temperature). The amount of DNA in the nuclei was determined using a Biolam-70 light microscope with photometry using an FMEL-1 component and an FEU-79A photometer in transmitted light with a blocking filter of maximum light transmission at a wavelength of

570 nm and a supplied voltage of 900 V. The results were subjected to the inverse decimal logarithm according to the formula:

$$A=LgUi/U_0,$$

where A – optical density;

Ui – voltage meter reading on the nucleus;

U<sub>0</sub> - voltmeter readings on unstained areas of the preparation.

Peripheral blood lymphocytes and small lymph nodes lymphocytes served as a diploid standard.

The immunohistochemical method was used to further evaluate the proliferative activity of hepatocytes after a mechanical injury to the hepatic that takes place under the use of biologically-active agents (Kumar & Rudbeck, 2011). For immunohistochemical studies, two commercial monoclonal antibodies by Santa Cruze were used: 1) Ki-67 proliferative activity marker; 2) a marker of apoptosis Bcl-2. Immunohistochemical studies were performed according to a standard protocol. Sections 3 μm thick were applied to high-adhesive glass treated with L-polisine and dried at room temperature for 24 hours. Staining was carried out manually and by hardware using immunohistochemical containers AUTOSTAINER-360 (THERMO, UK) and Leica BOND-MAX (Germany), as well as through Envision imaging systems (DACO Denmark) and NovoLincpolimer (NovoCastr, UK). Nonimmune rabbit and mouse sera, as well as sections of control hepatic tissues, served as a control of the sensitivity and specificity of the reaction. Results of the responses were evaluated by counting the number of stained nuclei per 200 hepatocyte nuclei in six fields of view. Then, the ratio of stained hepatocytes to the total number of hepatocytes was calculated, and the results were expressed as a percentage.

Statistical processing of digital data was carried out according to the particular program "Statistics" with the assistance of the Microsoft office software package (MS Word and MS Excel) on a Pentium 166 MMX computer. Statistical significance was determined by Student's t-test.

### 3. RESULTS AND DISCUSSION:

Histological changes one day after the operation were characterized by a predominance of dystrophic and necrobiotic changes in hepatocytes. Microscopic preparations of the hepatic taken from the site of injury revealed slit damage to the hepatic tissue, in which dead

hepatocytes and erythrocytes were noted. These changes have occurred in both experimental and control animals.

On the 3rd and, especially, the 5th day, a cluster of cells appeared on the periphery of the necrotic focus, represented by macrophages and lymphocytes. In control of infant rats, the intensity of the cellular inflammatory response was more pronounced in comparison with experimental animals, which visually showed a weaker presence of inflammatory cellular elements, macrophages, and lymphocytes around the injury site. On the 7th-9th day, in experimental animals, fibroblasts are fixed among inflammatory cells; fibrous connective tissue is formed 11 days after the operation. In control of infant rats, the appearance of fibroblasts is noted earlier (on the 5th-7th day), and, respectively, the formation of fibrous connective tissue occurs in them earlier - on the 9th day. Thus, among experimental rats, as well as in control, the fibrous connective tissue is found in place of the dead hepatic tissue (Figure 1). However, in experimental animals, it formed later, and the area of the connective tissue scar was 34.7% less than among control rats.

Starting from the first day after operation, hepatocyte proliferation was activated in hepatic of both experimental and control rats (Michalopoulos, 2010). Microscopic preparations revealed all phases of the mitotic cycle, from metaphases to late telophases. The number of mitoses in experimental animals was statistically significantly higher than in control animals ( $p < 0.001$ ). The peak of hepatocyte proliferation in experimental rats was observed in the period from 3 to 11 days; in control animals, the highest number of mitoses was recorded on days 3–7. Mitotic division in experimental pups was observed up to 20 days after the operation. In control, they were absent in the hepatic so far after 11 days, and until the end of the experiment.

Along with mitoses, starting from the 7th day after the operation, the number of binuclear hepatocytes in the hepatic increased; this was the case in animals of both groups, however, compared with the control, in experimental animals, there was a statistically significantly greater number ( $p < 0.001$ ). This trend was observed until the end of the experiment.

An immunohistochemical study confirmed the activation of hepatocyte proliferation: a statistically significant increase in Ki-67 positive nuclei was observed in experimental animals compared to control ones (Figure 2).

Most often, Ki-67 positive nuclei are determined on the 3.5 and 9 days after operation ( $p < 0.001$ ). Almost simultaneously with the activation of hepatocyte proliferation, their hypertrophy and polyploidy increased. From 3 days to 30 days, tetraploid nuclei began to predominate in animals. Moreover, in experimental rats, polyploidy was more pronounced, which manifested itself in the fact that tetraploid cells prevailed over diploid cells, in contrast to the hepatic of control rats. In experimental fetuses, hepatocytes of higher ploidy (8p, 16p, and even 32p) were often fixed, which was absent in control (Table 1).

Hypertrophy of hepatocytes and their nuclei began to increase from the 5th and, especially, from the 7th day, reaching the greatest value on the 20th and 30th days after the operation; in experimental fetuses, it was more pronounced. Restorative processes in the hepatic, especially in experimental rats, took place against the background of an increase in the vital activity of hepatic cells: an increase in the activity of SDH, NADH, NADPH was noted, the number of binucleate hepatocytes went up significantly, which indicates an increase in the protein-synthetic function of hepatic cells (Brodskaya et al., 2010) (Figure 3).

Electron microscopy revealed changes of two types. Hepatocytes with signs of degeneration, manifested by swelling of the mitochondria, focal enlightenment of the matrix, and also a change in the orientation of the cristae up to a decrease in their number in the cells, were observed. There was disorganization of the membranes of the organelles. At the same time, there were cells with changes that indicated the intensity of intracellular hyperplastic processes. This was manifested by hypertrophy and swelling of mitochondria, the convergence of the membranes of the endoplasmic reticulum, hypertrophy, and hyperplasia of ribosomes. These changes could be interpreted as a sign of intracellular regeneration.

Data obtained in the course of this work are generally consistent with the literature references on the morphogenesis of the healing of hepatic injury of various origins and development of regenerative manifestations (Baidyuk, Korshak, Karpov, Kudryavtsev, & Sakuta, 2012). In particular, present research revealed confirmation that healing of hepatic damage always occurs due to regenerative hypertrophy (Eltschaninov, 2011; Tournier-Thurneysen et al., 1992). Increase in the proliferation of hepatocytes was also expected, as it was repeatedly indicated in the

works of various authors (Celton-Morizur & Desdouets, 2010; Eltschaninov & Bolshakova, 2012; Malato et al., 2011; Sakuta, Baidyuk, Zhumagalieva, & Kudryavtsev, 2011; Solopaeva & Solopaev, 1991; Soltys & Zuevkiy, 2000; Yanger et al., 2014).

Also, in this study, the fact of an increasing number of binuclear hepatocytes (Berezovskiy, Yanko, Litovka, & Volovich, 2012; Stupin et al., 1995), and development of hypertrophy and polyploidy of hepatocytes (Soltys and Zuevkiy, 2000) was noted. Proliferation was activated against the background of increased protein-synthetic and enzymatic activity of hepatocytes, also earlier reported (Soltys and Zuevkiy, 2000). Even though all manifestations of a regenerative nature in experimental rats were more intense, complete organ restoration did not take place. Nevertheless, the focus of fibrosis that occurs at the site of dead hepatic tissue in experimental rats was visually much smaller than in control animals, which can be regarded as an encouraging fact, indicating that stimulation of hepatic regeneration is fundamentally possible (Koroy, Yagoda, Gilyazova, & Mukhoramova, 2014).

In previously published works (Juan, Benito, Alvarez, & Fabregat, 1992; Romanova, 2012; Romanova & Malyshev, 2012), an effect on the regeneration of fetal hepatic after a mechanical injury was studied separately for "Trepel" and "Suvar." "Trepel" when introduced into the diet of animals after the operation, is a powerful detoxification agent, which lowered the alternative processes in the hepatic of rat fetuses, suppressed the inflammatory reaction along the periphery of the injury site, and slowed the recruitment of fibroblasts into inflammatory infiltrate.

When only "Suvar" was used in the animal diet, in response to mechanical damage to the hepatic in rat fetuses, hepatocyte proliferation was activated (Romanova, 2012). Thus, "Trepel" and "Suvar", introduced into rat food in isolation, peculiarly influenced the healing morphogenesis but did not lead to a decrease in the size of the connective tissue scar that occurs in the hepatic at the area of dead tissue.

Significant in the study were the results of the combined effect of "Trepel" and "Suvar" biocorrectors on healing of mechanical injury of rat fetuses, which was realized in reducing the area of post-traumatic fibrous connective tissue by 34.7% compared with the control. This follows from the fact that combined action of "Trepel" and "Suvar" biocorrectors led to decrease in the intensity of

alternative manifestations in hepatocytes, reduced inflammatory changes around the injury site, and slowed the recruitment of fibroblasts to the area of injury, which, in turn, reduced the intensity of collagen formation. The described processes proceeded against the background of a revitalization of hepatocyte proliferation, which manifests itself in the form of activation of mitotic division, an increase in the number of binuclear hepatocytes, polyploidy and hypertrophy.

The theoretical significance of the results is that for the first time, data was obtained on the stimulating effect on rat hepatic regeneration using "Trepel" and "Suvar" biocorrectors. This may be a prerequisite for their further study in various pathological processes in mammals, both in the prenatal and postnatal periods. Successful surgical interventions in the organs of the mammals' fetuses, including hepatic (Chuvash State University named after I.N. Ulyanov Patent RU 2262135, 2005), were first performed in Russia; biocorrectors "Trepel" and "Suvar" is a purely Russian development. Literature references search established that abroad there are no works even closely related to this subject. Therefore, this study can attract attention abroad and stimulate further development of the problem.

#### 4. CONCLUSION:

Thus, in experimental animals, the size of the focus of fibrous connective tissue developing at the area of dead hepatic tissue was 34.7% smaller than in infant rats of the control group. The stimulating effect of biocorrectors on organ restoration is explained by their mechanism of action. It has been established that combined use of the "Trepel" and "Suvar" biocorrectors in veterinary medicine is accompanied by hypertrophy of the endocrine glands: adrenal glands (mainly their cortex), thyroid gland (follicular epithelium and follicles themselves), testes. This leads to an increase in production of the corresponding hormones. Female rats receiving biocorrectors as a food supplement feed their newborn rats with milk with a significantly higher hormone content.

The excess content of glucocorticoids in the body of experimental infant rats explains the absence of a pronounced inflammatory reaction around the injury and inhibition of collagen genesis. Iodine-containing thyroid hormones, activating all types of metabolism, sharply increase cellular metabolism, and stimulate the proliferation of hepatocytes. Thus, based on a change in the hormonal background of the

organism of experimental rats, it can be concluded with a high degree of probability that hypertrophied hepatic cells, while slowing down the development of connective tissue, mechanically compress the site of organ damage. Proliferating hepatocytes gradually fill the post-traumatic hepatic defect, as a result of which, along with the connective tissue, it is replaced for a considerable extent by newly formed and hypertrophic hepatocytes. This led to the fact that the size of the focus of fibrosis in experimental infant rats was 34.7% smaller than in control animals.

### RESUMO

*Salvia nemorosa* L. ou sálvia é uma fonte rica de metabólitos antimicrobianos e antioxidantes. Considerando a importância dessa planta medicinal e da diversidade fitoquímica entre suas populações para o consumo local e os adubos de reprodução, este estudo foi realizado para determinar e comparar a composição de óleo essencial (OE) das plantas sálvia coletadas em quatro regiões do noroeste do Irã, incluindo Ahar, Zonouz, Urmia e Ardabil em dois estágios de crescimento (vegetativo e florido) para finalmente demonstrar os efeitos do crescimento e localização nas características da OE. Os resultados mostraram que o teor de OE das flores nas regiões estudadas foi o mais alto em comparação com as fases vegetativa e florística. A porcentagem e o número de composições voláteis no OE de flores foram as que apresentaram a maior quantidade. Em Zonouz, 87,13% e 12 composições enquanto em Ahar, 80,20% e 19 composições. A menor porcentagem e o número de composições voláteis no OE da flor foi visto em Urmia, 78,56% e 13 composições enquanto em Ardabil, esses números foram 68,61% e 10 composições, respectivamente. O óxido de cariofileno teve o maior teor em todos os óleos essenciais extraídos, sendo o mais alto no estágio de floração das regiões de Zonouz, Ardabil e Urmia, respectivamente. Em Ahar, diferentemente de outras regiões, a maior porcentagem desse composto estava nas folhas da fase vegetativa. Os sesquiterpenos oxigenados aumentaram o teor de OE nas flores das regiões Urmia (46,31%), Zonouz 42,59% e Ardabil (45,60%). Em contraste com outras regiões, para a região de Ahar, a maior quantidade (36,18%) de sesquiterpenos oxigenados foi observada no OE das folhas do estágio de floração. Pode-se concluir que diferentes estágios de crescimento das plantas, época de colheita das plantas, condições ambientais, habitat principal e diferenças nas condições climáticas podem contribuir na concentração, tipo e porcentagem de compostos voláteis no OE da sálvia.

### ABSTRACT

*Salvia nemorosa* L. or wood sage is a rich source of antimicrobial and antioxidant metabolites. Considering the importance of this medicinal plant and phytochemical diversity among its populations for local consumption and breeding purposes this study was performed to determine and compare essential oil (EO) compositions of sage plants collected from four regions in the northwest of Iran including Ahar, Zonouz, Urmia, and Ardabil at two growth stages (vegetative and flowering) to finally demonstrate the effects of growth and location on EO features. The results showed the EO content of flowers in the studied regions were the highest in comparison with vegetative and flowering stages leaves. The percentage and the number of volatile compositions in the OE of flowers were those that presented the highest quantity. In Zonouz, 87.13% and 12 compositions while in Ahar, 80.20% and 19 compositions. The lowest percentage and the number of volatile compositions in the OE of flowers was seen in Urmia, 78.56% and 13 compositions while in Ardabil, these numbers were 68.61% and 10 compositions, respectively. Caryophyllene oxide had the highest content in all the extracted essential oils, being the highest in the flowering stage of the regions of Zonouz, Ardabil and Urmia, respectively. In Ahar, differently from other regions, the highest percentage of this compound was in the leaves of the vegetative stage. Oxygenated sesquiterpenes increased the EO content in the flowers of the regions of Urmia (46.31%), Zonouz 42.59% and Ardabil (45.60%). In contrast with other regions, for the region of Ahar, the highest quantity (36.18%) of oxygenated sesquiterpenes was observed in the OE of the leaves of the flowering stage. It can be concluded that different growth stages of plants, harvest time of plants, environmental conditions, main habitat and differences in climatic conditions can contribute to the concentration, type and percentage of volatile compounds in the EO of *Salvia*.

80.20%, and 19 compositions. The lowest percentage and the number of volatile compositions in the OE of the flowers were seen in Urmia, 78.56%, and 13 compositions, while in Ardabil, these numbers were 68.61% and 10 compositions, respectively. Caryophyllene oxide had the highest content in all essential oils extracted, being the highest in the flowering stage leaves of the regions of Zonouz, Ardabil, and Urmia, respectively. In Ahar, unlike other areas, the most significant percentage of this compound was in the leaves of the vegetative stage. The oxygenated sesquiterpenes increased in the EO content of the flowers of the Urmia (46.31%), Ardabil (45.60%) and Zonouz (42.59%) regions. In contrast to other areas, for the Ahar region, the highest amount (36.18%) of oxygenated sesquiterpenes was observed in the EO of the leaves of the flowering stage. It can be concluded that different plant growth stages, plant harvest time, environmental conditions, primary habitat, and differences in climatic conditions can contribute to the concentration, type, and percentage of volatile compounds in the *salvia* EO.

## چکیده

*Salvia nemorosa* L. یا مریم‌گلی چوبی دارای فعالیت‌های ضد میکروبی، آنتی‌اکسیدانی و منبعی غنی از متابولیت‌های فعال می‌باشند. با در نظر داشتن اهمیت این گیاه دارویی برای مصرف‌کنندگان محلی و اهداف اصلاحی این بررسی در راستای تعیین و مقایسه ترکیبات اسانس در گیاهان مریم‌گلی جمع‌آوری شده در چهار منطقه مختلف شامل زنوز، ارومیه، اردبیل و اهر و در دو مرحله رشد، رویشی و گل‌دهی صورت گرفت تا نهایتاً اثر مرحله رشد و مناطق رشد روی اجزای روغن‌های فرار تعیین گردد. نتایج نشان داد که درصد اسانس سرشاخه‌های گلدار در هر چهار منطقه مورد مطالعه در مقایسه با برگ‌های مراحل رویشی و گل‌دهی از بالاترین میزان برخوردار بودند. بیشترین درصد و تعداد ترکیبات فرار روغن‌های فرار در اندام زایشی مشاهده گردید. با 87.13% و 12 ترکیب در منطقه زنوز، 80/20% و 19 ترکیب در منطقه اهر بالاترین میزان ترکیبات برخوردار بودند. کمترین میزان درصد اسانس با 78.56% و 13 ترکیب در منطقه ارومیه و با 68.61% و 10 ترکیب در منطقه اردبیل مشاهده شد. کاربوفیلین اکساید بالاترین میزان ترکیبات فرار شناسایی شده به ترتیب در اسانس گل‌ها، برگ‌های مراحل رویشی و گل‌دهی در هر چهار منطقه بود. بالاترین درصد کربوفیلین اکساید در برگ مرحله گل‌دهی هر سه منطقه زنوز، اردبیل و ارومیه دیده شد. از سوی دیگر بالاترین درصد این ترکیب در منطقه اهر برخلاف سایر مناطق در برگ مرحله رویشی بود. سسکوئیت‌ترین‌های اکسیژن‌دار در اسانس گل‌های مناطق ارومیه (46.31%)، اردبیل (45.60%) و زنوز (42.59%) افزایش داشتند. در منطقه اهر بر خلاف سایر مناطق، بالاترین میزان سسکوئیت‌ترین‌های اکسیژن‌دار در اسانس برگ مرحله گل‌دهی (36.18%) مشاهده شد. می‌توان این‌گونه نتیجه گرفته که مراحل مختلف رشد گیاه، زمان برداشت گیاه، تاثیر شرایط محیطی، زیستگاه اصلی و اختلاف در شرایط اقلیمی می‌توانند بر نوع و درصد ترکیبات فرار اسانس گیاهان مریم‌گلی تاثیر داشته باشند.

کلمات کلیدی: *Salvia nemorosa*، متابولیت‌های ثانویه، روغن‌های فرار، کاربوفیلین اکسید، سسکوئیت‌ترین‌ها

## 1. INTRODUCTION:

*Salvia* L. is the largest genus of Lamiaceae (tribe Mentheae) with nearly 1000 species (Walker and Sytsma, 2007, Sarac and Ugur, 2007). The genus *Salvia* is derived from the Latin word "Salvare" meaning "to heal" or "to be safe and unharmed," referring to the medicinal properties of the genus (Walker *et al.*, 2004, Giuliani and Maleci Bini, 2008). The members of the genus display a remarkable diversity in growth form, floral morphology, pollination biology, and secondary compounds; they are distributed all around the world (Walker *et al.*, 2004). The genus *Salvia* is represented in Iran by 58 species, 17 of which are endemic (Mozaffarian, 1996, Ipek, 2012).

Many species of *Salvia* are used in traditional medicine throughout the world. In Iranian folk medicine, several *Salvia* species have been used as antiseptic for wounds, as a diuretic, stomach tonic, antifatulent, and constituent, and for the treatment of eye disorders, diarrhea, dyspepsia, fever, rheumatism, excessive

menstruation, common cold, coughing, pertussis, and sinusitis (Naghibi, 2005, Ozkan, 2008, Raal *et al.*, 2007). *Salvia nemorosa* L., commonly known as wood sage, is growing in central Europe and Western Asia (Skala and Wysokinska, 2004).

Leaves of *S. nemorosa* are traditionally used in Turkish folkloric medicine for stop bleeding when applied externally (Takeda *et al.*, 1997; Topcu, 2006). Also, in the Bulgarian traditional medicine, *S. nemorosa* is used mainly for the treatment of stomach ache, diarrhea, hemorrhages, and furuncles (Daskalova, 2004, Farimani *et al.*, 2013). In Russia, *S. nemorosa* is utilized for much the same ailments as *S. officinalis*. Studies have shown that *S. nemorosa* is a rich source of bioactive metabolites (flavonoids and oxygenated sesquiterpenes). Also, *S. nemorosa* exhibited considerable antibacterial, antioxidant, and enzyme inhibitory activities. In conclusion, *S. nemorosa* is a valuable source of natural products and could be used for preparing novel functional foods, cosmetics, and pharmaceutical ingredients (Bahadori, 2017,

Bahadori and Mirzaei, 2015, Wu *et al.*, 2012). In studies conducted by Coisin *et al* (2010) in the volatile oil extracted from *Salvia nemorosa* L. in plant development stage, 22 compounds have been identified. The main chemical compounds belong to monoterpenes group with having antiseptic (bactericide), carminative, antispastic and diuretic properties such as: sabinene (33.93%),  $\beta$ -cariophyllene (19.86%),  $\beta$ -cubebene (11.87%),  $\alpha$ -cariophyllene (6.37%) and other compounds included cariophyllene oxid,  $\gamma$ -terpinene, Limonene,  $\alpha$ -tujone,  $\beta$ -mircene,  $\beta$ -pinene,  $\gamma$ -terpinene, cimol, elixene, terpinolene,  $\beta$ -burbonene, alloaromadendrene oxid (1)  $\gamma$ -cadinene, alloaromadendrene oxid (2)  $\alpha$ -pinene  $\gamma$ -cadinene, pulegone,  $\alpha$ -terpinil-acetate (Coisin *et al*, 2010).

Also, a study on *S. nemorosa* showed that the chemical compositions in leaves and flowers essential oils were sesquiterpenes hydrocarbons, oxygenated sesquiterpenes, and monoterpene hydrocarbons in the highest amount and oxygenated monoterpenes, aliphatic compounds, monoterpene hydrocarbons, sabinene, and limonene were in the lowest amount. In addition, phenolic compounds of *salvia nemorosa* are gallic acid, protocatechuic acid catechin, *p*-hydroxybenzoic acid, caffeic acid, epicatechin, vanillin, *p*-coumaric acid, ferulic acid, sinapic acid, benzoic acid, *O*-coumaric acid, rutin, naringin, hesperidin, rosmarinic acid, trans-cinnamic acid, quercetin, luteolin, kaempferol, apigenin (Bahadori *et al*, 2017).

The aim of this study was to evaluate the composition and comparison of *Salvia nemorosa* essential oils of plants collected plants in four different regions (northwest of Iran) and at two growth stages. This study will allow the realization of two key scientific points in which one is determining the best time of harvest with aromatic properties (quality) or optimal therapeutic properties and the most useful plant origin on its phytochemical compositions. This may help increase the economic efficiency of the production of essential oils and the acquisition of new scientific data on the change in secondary volatile metabolites of sage plants during its phenological cycle that can be utilized by local consumers as well as medicinal plant breeders.

## 2. MATERIALS AND METHODS:

Sage plants (*salvia nemorosa* L.) were collected at two vegetative and flowering stages from four regions in the northwest of Iran including Ahar (75 km from Tabriz to Ahar) (longitude: 38.26

° E' , latitude: 47.04° N and altitude:1391m ) and Zonouz gardens (longitude: 38.26° E' , latitude: 45.46° N and altitude:1550 m) in East Azarbaijan, Urmia, Qasemlu village (longitude: 37.65 ° E', latitude: 47.05° N and altitude:1328m) in western Azarbaijan and Ardabil, Abbasabad village (85 km from khalkhal to Ardabil) (longitude: 38.13° E' , latitude: 48.19° N and altitude:1335 m) in Ardabil province (Figures 1, 2 and Table 3). Plant collection times at the vegetative stage were May 12th to May 26th, 2017, and collection times at the flowering stage were May 19th to June 5th, 2017. After collecting the plants, they were dried at room temperate.

### 2.1. Extraction and analysis of essential oils by GC-MS

After collecting plants at two growth stages (vegetative and flowering) from different regions and after drying them in the shade, essential oils extracted by water distillation using the Clevenger apparatus and then analysis by GC-MS. Therefore, flowers and leaves of plants (vegetative and flowering stages) underwent distillation using Clevenger apparatus for 4 hours. Then, essential oils were kept in the refrigerator at the 4°C and when analyzing they were separated from water and dried over anhydrous sodium sulfate and for identification of essential oils composition was injected to GC-MS (The working conditions were adjusted based on helium as the carrier gas at the rate of 2 mL.min, ionization potential of 70 eV, and mass range of 40-300 u, and column temperature programming was done with the column temperature variation of 60-280 °C at the rate of 3°.min and the injection chamber temperature of 280°C. In each case, after the injection of very small quantities of essential oil (0.1  $\mu$ L), chromatograms were obtained and the mass spectra of various compounds were examined. Then, the spectra were identified and studied. The individual compounds were identified by MS and their identity was confirmed by comparing their retention indices relatives to C8 –C32 n-alkanes and by comparing their mass spectra and retention times with those of authentic samples or with data already available in the NIST library and literature Adams (Adams, 2017).

Identification of GC/MS chromatogram spectra was performed using mass database (Adams, 2017), inhibition index, study of mass spectra of each essential oil component and comparison with standard spectra and the Quatts formula was used to calculate the inhibition index.

### 3. RESULTS AND DISCUSSION:

The results of the composition of sage (*Salvia nemorosa* L.) essential oils in two phenological stages of vegetative and flowering stages showed that in each regions (Ahar, Zonouz, Ardabil and Urmia) separately, essential oils of sage flowers had the highest percentage of components in comprising with essential oils of sage vegetative stage leaves and flowering stage leaves, in which according to Figure 3, the essential oil of *S. nemorosa* flowers had the highest percentage in comparison with the essential oils of vegetative stage leaves and flowering stage leaves in Zonouz, Ahar, Urmia and Ardabil regions so that, the essential oil of sage flowers in Zonouz region had the highest percentage and in Ardabil region showed the lowest percentage. In addition, by comparing the number, type and percentage of identified volatile compound in the essential oil of *S. nemorosa* flowers in every four regions was seen that, the essential oils of flowers of Zounoz region with 12 compounds had the highest of the percentage of essential oils (87.13%) comprising of the essential oils of flowers in other regions while, in the essential oils of flowers of Ardabil region, there were 10 compounds with 68.61% of total oils. In the essential oils of flowers of Ahar region 20 compounds with 80.20% of total oils and in the essential oils of flowers of Urmia region 14 compounds were identified with 78.56% of total oils (Tables 1 and 2; Figure 5 a, b, c, d).

The essential oil of vegetative stage leaves in Urmia and Ahar regions had the lowest percentage and the essential oil of vegetative stage leaves in Ardabil and Zonouz regions increased in comparison with flowering stage leaves (Tables 1 and 2; Figures 3 and 7 a, b, c, d).

Among identified volatile compounds in the essential oils of flowers in Ahar, Zouoz, Urmia and Ardabil regions, respectively, caryophyllene oxide, spathulenol and trans caryophyllene were the main compounds of essential oils. In addition to, compounds such as para cymene, sabinene, terpinen-4-ol, were another main compounds in the essential oils of flowers in Ahar region, para cymene, 1-octen-3-ol were another main compounds in the essential oils of flowers in Urmia region, terpinen-4-ol, camphor and para cymene were another main compounds in the essential oils of flowers in Zounoz region and 1-octen-3-ol was another main compound in the essential oils of flowers in Ardabil region (Table 1 and 2).

In the study of Kashef *et al* (2019) on growth compatibility and medicinal potential of four

*Salvia* species in Semnan climatic conditions, was observed that, in *S. nemorosa* species in seedling stage, caryophyllen (43.91%), caryophyllen oxide (19.65%) and farnesene (12.13%), in meddle of growth seasen, trans-caryophyllen (11.93%), caryophyllen oxide (37.89%) and trans-  $\beta$  farnesene (11.49%) and in the end of growth seasen, trans- caryophyllen (28.94%), caryophyllen (30.13%) and  $\alpha$ - cadinol (5.69%) were the main of composition. In *S. sclarea* and *S. officinalis* plants in seedling stage caryophyllen, caryophyllen oxide, germacrene D, in middle of growth seasen caryophyllen, caryophyllen oxide, trans- $\beta$  farnesene and  $\beta$ - bourdonen, in the end of growth seasen caryophyllen oxide,  $\beta$  farnesene and germacrene D with different percentage were the main of composition (Kashef *et al*, 2019).

In the essential oils of flowering stage leaves in Ahar region 14 volatile compounds with 69.18% of total essential oils, and in Zounoz region only one volatile compound was identified with 8.48% of total essential oils. Also, In the essential oils of flowering stage leaves in the two regions of Urmia and Ardabil, 7 and 4 of volatile compounds, respectively, were identified with almost 58.89% of total oils (Tables 1 and 2; Figure 6 a, b, c, d).

Among the identified volatile compounds in the essential oils of flowering stage leaves in each four studied regions, caryophyllene oxide then Beta- ionone had the highest percentage so that, the highest amount of caryophyllene oxide was seen with 39.40% in the essential oils of flowering stage leaves in Ardabil region and the lowest amount of caryophyllene oxide was seen with 8.48% in the essential oils of flowering stage leaves in Zounoz region. In addition to, 1-octen-3-ol and camphor in the essential oils of *S. nemorosa* L. in Ardabil and Urmia regions and camphor, trans caryophyllene ,1-Octen-3-ol in the essential oil of sages plants in Ahar region were main compound (Table 1 and 2).

Extraction and identification of essential oils volatile compounds showed existence of 10 volatile compounds with 55.54% and 63.89% of total essential oils in vegetative stage leaves of sage collected from Ahar and Ardabil regions. While, essential oil of vegetative stage leaves in Urmia region showed only two volatile compounds with 24.62% of total essential oils. In addition to, essential oils of vegetative stage leaves in Zonouz region showed three volatile compounds with 41.29% of total essential oils. Among identified volatile compounds caryophyllen oxide showed the highest percentage in essential oils of vegetative stage leaves each four regions (Ahar,

Zonouz, Urmia and Ardabil). So that, the highest percentage of caryophyllen oxide was in essential oil of vegetative stage leaves in Ardabil region (31.35%) and the lowest percentage caryophyllen oxide was in essential oils of vegetative stage leaves in Urmia (18.19%). In addition, trans-beta caryophyllen was part of main compound in essential oils of vegetative stage leaves in Ahar, Ardabil and Zonouz regions (Table 1 and 2).

It was reported that existence of compounds such as caryophyllen oxide, beta-caryophyllen, germacrene D and germacrene B were the main compounds of essential oils in *S. nemorosa* and *S. virgata* harvested from Iran (Sefidkon and Mirza, 1999).

By comparing of chemical groups in essential oils of flowers, vegetative stage leaves and flowering stage leaves in all regions (Ahar, Zonouz, Urmia and Ardabil) was observed that oxygenated sesquiterpenes in essential oils were the highest percentage of chemical groups (Figure 4). So that, the highest percentage of oxygenated sesquiterpenes were with 46.31% in essential oils of flowers of sage plants in Urmia region and the lowest percentage of oxygenated sesquiterpenes were seen with 25.60% in essential oils of sage plants in Ahar region (Table 1 and 2, Figure 4).

In essential oils of flowering stage leaves, the highest amount oxygenated sesquiterpenes were with 44.05% in essential oils of sage plants in Ardabil region and the lowest amount this chemical groups were observed with 8.48% in Zonouz region. Also, oxygenated sesquiterpenes showed the highest amount with 37.21% and 34.3%, respectively, in essential oils of vegetative stage leaves in Ardabil and Ahar regions and showed lowest amount with 18.19% in essential oils of vegetative stage leaves in sage plants in Urmia region (Table 1 and 2, Figure 4).

In a study on the composition of essential oils of some wild salvia species growing in Serbia was observed that in the essential oil of *S. nemorosa* flowers, caryophyllen oxide, beta-caryophyllen, sabinene and germacrene D and in the essential oil of *S. glutinosa* flowers, caryophyllen oxide, spathulenol, humulene epoxide were major compositions. In addition, in the essential oils of *S. nemorosa* and *S. glutinosa* plants, sesquiterpenes were the main chemical groups (Chalchat, 2004).

In Yayli *et al* (2010) study on constituents of the essential oil from the flower, leaf and stem of *Salvia viridis* L. grown in Turkey, sesquiterpenes hydrocarbons were the main constituents in organs and the major components in the essential

oils of leaf were  $\beta$ -pinene,  $\beta$ -copaene, trans-muurola-4(14),5-dien which, showed significant difference in the type and percentage of identified compound of *S. nemorosa* essential oil in this study (Yayli *et al.*, 2010).

Comparing the identified compounds in this study with other reports shows the similarities and differences in terms of the type and amount of identified composition. These differences may be due to a variety of reasons, including the time of harvested and the ecological conditions of the sage plants, which can affect the amount and type of compound and it could be due to the collection of *S. nemorosa* plants from different natural environments, which can be said that the results obtained are due to the interaction of genetic factors and the environment (Maskimovic *et al.*, 2007; Figueiredo *et al.*, 2008).

The quantity of active ingredients in medicinal plants is mainly affected by natural variables in the environment. Although the amount of secondary metabolites is under the control of genes, their quantity and accumulation are significantly affected by environmental conditions. Climatic variations and different ecological conditions have caused diversity and richness in medicinal plants throughout Iran (Ebrahimpour *et al.*, 2009, Figueiredo *et al.*, 2008, Russo *et al.*, 2013).

The major habitat conditions in different areas include height, slope direction and percentage, latitude and longitude, temperature, humidity and annual rainfall, soil characteristics, and associated species (Bakhshi *et al.*, 2010, Cheynier *et al.*, 2013, Maksimovic *et al.*, 2007). Considering the growth location of the plant in the environment is one of the main factors of great impact on essential oil and active ingredients. Some reports have expressed associations between the habitat conditions and chemical compounds of plants, manifesting a high correlation between the geographical origin of plants and their active ingredients characteristics between them (Omidbeigi, 2009, Li *et al.*, 2015, Ben farhad, 2009). Furthermore, edaphic and climatic variations and genetic characteristics may have a strong influence on the morphological, agronomic and essential oil chemical characteristics (Mossi *et al.*, 2011, Papageorgiou *et al.*, 2008).

As a result, in this study, different stage of growth of *S. nemorosa* plants, harvest times, different in climatic condition, major habitat and direct relation between ecological and genetic factors have led to differences in the type and

percentage of identified composition in the essential oils of sage plants in Ahar, Ardabil, Zonouz and Urmia regions.

#### 4. CONCLUSIONS:

On the basis of all the analyses, it could be concluded that oxygenated sesquiterpenes were the highest percentage of compounds identified in the essential oils of flowers, vegetative stage leaves, flowering stage leaves in four regions. Also, Sesquiterpene hydrocarbons, oxygenated monoterpenes, and monoterpene hydrocarbons there were in a lower percentage. The main oxygenated sesquiterpene was caryophyllene oxide in essential oils. The most number and the highest rate of the volatile compound identified was seen in essential oils of *S. nemorosa* flowers collected from Zonouz region. It confirms the influence of environmental conditions (harvested time, original habitat and differences in climatic conditions) on the nature of plant chemical composition that has the vital role in plant adaptation and speciation.

## RESUMO

Com o aumento na produção de peixes em sistemas de pisciculturas, principalmente tilápias, o uso do hormônio 17 $\alpha$ -metiltestosterona (MT) como indutor da masculinização de alevinos cresceu conjuntamente. A probabilidade de contaminação de recursos naturais também tende a aumentar e não há legislação brasileira que regulamente o teor deste hormônio em águas. O estudo da interação do hormônio com o solo típico das regiões produtoras é importante para compreender os fatores que influenciam a sua adsorção. Este trabalho utilizou duas amostras de Latossolos Vermelhos Eutroféricos e avaliaram-se as condições de interação do hormônio em processo estático (repouso) e dinâmico (agitação), utilizando-se modelos de isotermas. Os resultados mostraram que o maior teor de matéria orgânica do solo e a maior salinidade do meio aquoso aumentam a adsorção da MT em solo no processo estático. Para o processo dinâmico, o teor de Fe tem influência na maior adsorção em solo. O pH do meio não influencia na adsorção em nenhum dos processos. A adsorção possui características exotérmicas sendo que o equilíbrio de adsorção é atingido em 24 horas e o modelo de Freundlich para a amostra do solo 1 e o modelo de Temkin para a amostra do solo 2 são os que mais se adequam ao processo de adsorção. Segundo parâmetros calculados para a isoterma de Dubinin, tem-se que as adsorções dos solos possuem a tendência de apresentar interações químicas entre adsorvente-adsorvato. Estes resultados mostram a preocupação com a quantidade de hormônio adsorvida em sedimentos em tanques de pisciculturas e sua liberação para o corpo d'água, com possibilidade de contaminação de recursos naturais.

**Palavras-chave:** masculinização, piscicultura, sedimento, isoterma.

## ABSTRACT

With the increase in fish production in fish farming systems, mainly tilapia, the use of the hormone 17 $\alpha$ -methyltestosterone (MT) as an inducer of the masculinization of fry has grown together. The probability of contamination of natural resources also tends to increase, and there is no Brazilian law that regulates the content of this hormone in waters. The study of the interaction of the hormone with the typical soil of the producing regions is essential to understand the factors that influence its adsorption. This work used two samples of Eutropheric Red Oxisols and the conditions of the interaction of the hormone in static (resting), and dynamic (agitation) processes were evaluated, using isothermal models. The results showed that the higher organic matter content of the soil and the higher salinity of the aqueous medium increases the adsorption of MT in the soil in the static process. For the dynamic process, the Fe content influences the higher adsorption in soil. The pH of the medium does not affect the adsorption in any of the processes. The adsorption has exothermic characteristics, and the adsorption equilibrium is reached in 24 hours, and the Freundlich model for the soil 1 sample and the Temkin model for the soil 2 sample is the most suitable for the adsorption process. According to parameters calculated for the Dubinin isotherm, soil adsorption tends to have chemical interactions between adsorbent-adsorbate. These results show concern for the amount of adsorbed hormone sediment in fish farming tanks and their release to the water body, with the possibility of contamination of natural resources.

**Keywords:** Masculinization, fish farming, sediment, isotherm.

## 1. INTRODUÇÃO:

O crescimento populacional humano ocasionou o aumento na produção e consumo de alimentos e, entre eles, o de peixes. A piscicultura vem obtendo destaque no setor do agronegócio e em 2018 registrou a produção nacional de 519,2 mil toneladas, sendo que deste montante, a tilápia (*Oreochromis niloticus*) representou 58,4% do total da despesa brasileira (IBGE, 2019). De acordo com estudo realizado pela Embrapa, a produção de tilápia no Brasil expandiu-se 223% entre 2005 e 2015 (Araújo & Reinol, 2017).

O estado do Paraná vem se destacando cada vez mais na produção nacional de viveiros de peixes e a espécie mais cultivada é a tilápia. No estado paranaense, a produção de pescados tem suma importância nas cidades situadas no Oeste do Estado, nas quais o Valor Bruto da Produção representa 60% do total (Agência de notícias do Paraná, 2019).

Em seu *habitat* natural, a tilápia apresenta-se tanto no sexo feminino quanto no masculino, mas a superpopulação é um problema bastante comum em viveiros. Para contornar isto, técnicas de masculinização dos alevinos são adotadas, obtendo-se melhor desempenho na produção dos pescados (Baldisserotto, 2002). Do ponto de vista econômico, espécies fêmeas gastam muita energia durante a reprodução e com cuidados com a prole; já os machos têm maior peso e maior quantidade de carne, favorecendo o setor produtivo (Oliveira, Santos, Pereira & Lima, 2007).

O processo de masculinização ocorre principalmente por meio da adição do hormônio sintético 17 $\alpha$ -metiltestosterona (MT) à ração administrada aos alevinos, durante os primeiros 30 dias de vida, quando o sexo ainda não está definido (Kubitza, 2009) (Figura 1).

**Figura 1.** Estrutura molecular da 17 $\alpha$ -metiltestosterona. Fonte: ChemSpider (Copyright Royal Society of Chemistry, 2020).

No entanto, o uso intensivo de MT adicionada à ração (60 mg kg<sup>-1</sup>) em pisciculturas ainda suscita preocupações quanto aos riscos para os consumidores e para a saúde ambiental

(Mlalila, Mahika, Kalombo, Swai & Hilonga, 2015). As rotas de contaminação da água envolvem ração não consumida e a eliminação do hormônio não metabolizado (Green & Teichert, 2000). Hormônios esteroides como a MT são rapidamente absorvidos pelos sedimentos devido à sua natureza hidrofóbica e a sua eliminação por meio de processos de biotransformação ou de fotodegradação dependem de vários fatores, como pH, teor de matéria orgânica do meio e salinidade (Green & Teichert, 2000; Kolok & Sellin, 2008; Homklin, Ong & Limpiyakorn, 2011; Ong, Chotisukam & Limpiyakorn, 2012; Young, Latch, Mawhinney, Nguyen, Davis & Borch, 2013; Mlalila, Mahika, Kalombo, Swai & Hilonga, 2015).

Espécies relativamente apolares como a MT presentes nos sedimentos podem ser liberadas para o meio aquoso em reações de equilíbrio químico, ocasionando a contaminação nos tanques e consequente contaminação dos ecossistemas aquáticos, afetando o equilíbrio do *habitat* natural dos organismos ali presentes (Ribeiro, 2001; Baldisserotto, 2002). A legislação brasileira é omissa quanto aos limites máximos permitidos para este hormônio no ambiente (Brasil, 2009; Brasil, 2013).

Os trabalhos disponíveis na literatura científica sobre o processo de adsorção da 17 $\alpha$ -metiltestosterona em sedimentos são escassos e abordam solos e condições que não são típicas do clima tropical (Fitzpatrick & Contreras-Sanchez, 2000; Lee, Strock, Sarmah & Rao, 2003; Kim, Zhiqiang, Baohua & Weillen, 2007 e Ong, Chotisukam & Limpiyakorn, 2012), mostrando a importância de estudos em solos típicos das regiões nas quais se situam as pisciculturas.

Assim, este trabalho estudou o processo termodinâmico e cinético da adsorção do hormônio 17 $\alpha$ -metiltestosterona em solos padronizados por meio de método dinâmico (agitação) e estático (repouso) e a isoterma que melhor descreve o conjunto de dados obtidos.

## 2. MATERIAL E MÉTODOS:

### 2.1. Procedimentos gerais

Todos os reagentes utilizados foram de alto grau de pureza (P.A.). A água utilizada para o preparo de soluções padrões ou diluições de amostras foi destilada e purificada por osmose reversa (ADAMO, resistência da água de 5 M $\Omega$  cm<sup>-1</sup> a 25°C). Duas amostras de solos padronizados secos ao ar, com classificação de

Latossolos Vermelhos Eutroféricos, foram obtidas a partir do laboratório de solos da Cooperativa Central de Pesquisa Agrícola (COODETEC – Cascavel/PR), coletados de 0 a 20 cm de profundidade, cuja caracterização está apresentada na Tabela 1, a partir do laudo do laboratório.

A solução estoque de  $17\alpha$ -metiltestosterona foi preparada a partir da diluição de 0,0302 g do hormônio (DanubioAqua, pureza de  $101,5 \pm 2\%$ ) em 1 mL de etanol (Vetec, 95% v/v). A partir da solução estoque, transferiu-se alíquota de 20  $\mu$ L com micropipeta (Labmate,  $\pm 0,82\%$ ), para balão volumétrico de 50 mL, completando-se o volume com água purificada, com concentração final de  $3,994 \times 10^{-5}$  mol L<sup>-1</sup>. As massas do hormônio e dos solos foram pesadas em balança analítica Shimadzu ( $\pm 0,0001$  g).

As medidas de absorvâncias na região do UV-visível das soluções e dos sobrenadantes foram realizadas em espectrofotômetro Shimadzu 1800 PC com o uso de cubetas de quartzo de caminho ótico de 1,0 cm e varredura nos comprimentos de onda de 200 a 700 nm e resolução de  $\pm 0,1$  nm.

Nos sobrenadantes também se determinou o pH utilizando-se pHmetro de bancada BEL (modelo PHS3BW), calibrado com solução tampão (Buffer) pH  $4,00 \pm 0,02$  e pH  $7,00 \pm 0,02$  (DINAMICA). A condutividade foi medida por meio do condutivímetro MS TECNOPON, com eletrodo de platina (constante de celda de 0,1), calibrado com solução padrão de condutividade  $1412 \mu\text{S cm}^{-1}$  (NEON).

## 2.2. Curva padrão de $17\alpha$ -metiltestosterona

A partir da solução estoque de  $17\alpha$ -metiltestosterona, prepararam-se 13 soluções de 50 mL entre as concentrações de  $2,39 \times 10^{-8}$  mol L<sup>-1</sup> e  $3,994 \times 10^{-5}$  mol L<sup>-1</sup>, obtendo-se a curva analítica que foi utilizada para determinar a concentração de MT a partir das absorvâncias dos sobrenadantes.

## 2.3. Ponto de carga zero (PCZ) dos solos

O valor do Ponto de Carga Zero (PCZ) foi obtido pela mistura de 0,5000 g do solo estudado em 50 mL de solução aquosa de KCl (Vetec, 99-100,5%) na concentração de  $0,5 \text{ mol L}^{-1}$  em valores de pH inicial variando de 3 à 11 as quais foram obtidas com soluções de HCl (Vetec, 37%) ou NaOH (Vetec, 99%) na concentração de  $0,01 \text{ mol L}^{-1}$ . As soluções permaneceram por 24 horas

em contato com os adsorventes sob agitação em mesa agitadora (NewLab), a 110 rpm e 25°C e foram obtidos os valores finais de pH.

## 2.4. Adsorção estática

Transferiu-se 50 mL da solução padrão  $3,994 \times 10^{-5}$  mol L<sup>-1</sup> de MT para proveta de vidro de 100 mL ( $\pm 0,05$ ) contendo 10 cm<sup>3</sup> de volume do solo, tampando-se em seguida e armazenando-se em local protegido da luz. O volume utilizado foi baseado em protocolos de análise de solos (von Raij, 2001). O pH, a condutividade e a absorvância dos sobrenadantes foram determinados semanalmente pelo período de seis semanas. Para o controle utilizou-se água purificada.

A determinação de Fe total no sobrenadante foi realizada empregando a técnica de espectrometria de Fluorescência de Raios X por reflexão total (TXRF) (S2 PICOFOX, Bruker AXS Microanalysis GmbH). Adicionou-se 660  $\mu$ L de amostra em microtubos do tipo Eppendorf com capacidade de 2 mL, nos quais foram adicionados 10  $\mu$ L de solução padrão de Gálio com concentração final na amostra de  $10 \text{ mg L}^{-1}$ . Posteriormente à adição do padrão interno, 5  $\mu$ L das amostras foram pipetados sobre o centro de discos de quartzo. Os discos contendo as amostras foram secos em capela de fluxo laminar à temperatura ambiente. Previamente às análises, os discos de quartzo (30 mm de diâmetro e 3 mm de espessura) foram submetidos a procedimento de limpeza conforme descrito por Espinoza-Quñones, Módenes, de Paula & Palácio (2015).

## 2.5. Determinação do pH em cloreto de cálcio

A partir do protocolo estabelecido por von Raij (2001), transferiu-se 10 cm<sup>3</sup> do solo em recipiente de plástico, adicionando-se 25 mL de solução de cloreto de cálcio ( $\text{CaCl}_2$ )  $0,01 \text{ mol L}^{-1}$ , permanecendo em repouso durante 10 minutos. Em seguida, agitou-se a mistura pelo período de 20 minutos em 110 rpm, usando agitador com movimento circular horizontal, e deixou-se descansar novamente por 10 minutos. Mergulhou-se o eletrodo na suspensão, sem agitar a solução, de modo que a ponta do eletrodo de vidro toque ligeiramente a camada de sedimento e a saída do eletrodo de referência fique submersa. Mediu-se o pH após estabelecido o equilíbrio.

## 2.6. Medida de adsorção com o tempo

As medidas de cinética de adsorção foram realizadas em recipientes plásticos contendo 0,5000 g de cada solo e adicionando-se 50 mL da solução padrão de 17 $\alpha$ -metiltestosterona em pH 5,5 e temperatura de 25,0 °C  $\pm$  0,1 realizadas no intervalo de 1 a 27 horas.

## 2.7. Adsorção dinâmica a 25 °C

Adicionou-se 50 mL da solução padrão 3,994 x 10<sup>-5</sup> mol L<sup>-1</sup> de MT em recipiente plástico contendo 0,5000 g de cada solo estudado e transferiu-se estes para uma mesa agitadora (NewLab) a 110 rpm, controlando-se a temperatura em 25°C  $\pm$  0,1. Após o período de 24 horas de agitação, centrifugou-se as amostras durante 30 minutos a 4000 rpm.

Utilizando as concentrações finais e iniciais, determinou-se a quantidade do hormônio adsorvida por grama de cada material adsorvente ( $q_{eq}$ ), utilizando-se a Equação 1.

$$q_{eq} = \frac{(C_i - C_{eq})}{M} \times V \quad (1)$$

sendo  $C_i$  e  $C_{eq}$  são as concentrações (mg L<sup>-1</sup>) iniciais e finais do hormônio em solução respectivamente,  $V$  é o volume da solução (L) e  $M$  é a massa do adsorvente em solução.

## 2.8. Adsorção dinâmica em diferentes pHs

Em nove recipientes plásticos contendo 0,5000 g de cada solo adicionou-se 50 mL da solução padrão de MT, ajustou-se os pHs de 3 a 11 utilizando-se soluções de NaOH (Vetec, 99%) ou HCl (Vetec, 37%) 0,1 mol L<sup>-1</sup> e, em seguida, transferiu-se as amostras para uma mesa agitadora (NewLab) a 110 rpm controlando a temperatura em 25  $\pm$  0,1°C. Após o período de 24 horas de agitação centrifugou-se as mesmas durante 30 minutos a 4000 rpm.

## 2.9. Estudos de Isoterma de Adsorção

Em recipientes plásticos contendo 0,5000 g de cada solo estudado adicionou-se 50 mL das soluções de MT nas concentrações de 6,0 x 10<sup>-6</sup>, 7,0 x 10<sup>-6</sup>, 8,0 x 10<sup>-6</sup>, 9,0 x 10<sup>-6</sup>, 1,0 x 10<sup>-5</sup>, 2,0 x 10<sup>-5</sup>, 3,0 x 10<sup>-5</sup>, 4,0 x 10<sup>-5</sup> mol L<sup>-1</sup>, corrigindo-se o pH das amostras entre 5,0 e 6,0 com solução de HCl ou solução de NaOH 0,01 mol L<sup>-1</sup>. Transferiu-se estes frascos para uma

mesa agitadora (NewLab) a 110 rpm controlando a temperatura pelo período de 24 horas de agitação (período pré-estabelecido por meio de estudos cinéticos). Este procedimento foi realizado para as temperaturas de 25, 35, 45 e 55°C.

## 3. RESULTADOS E DISCUSSÃO:

A Figura 2 apresenta os espectros característicos do hormônio MT em diferentes concentrações, na região do ultravioleta-visível e a curva analítica obtida.

A curva analítica da 17 $\alpha$ -metiltestosterona (Figura 2) apresenta correlação linear entre absorvância e concentração do hormônio com equação da reta igual a  $Abs = 0,01471 + 21233,63878[MT]$  e  $R^2 = 0,9981$ , entre as concentrações de 5,0 x 10<sup>-6</sup> a 4,0 x 10<sup>-5</sup> mol L<sup>-1</sup>.

A Figura 3 apresenta os resultados das medidas do ponto de carga zero (PCZ). Para o solo 1 o valor ocorre no pH 4,63 e para o solo 2 ocorre no pH 4,71. Já a Figura 4 apresenta a quantidade adsorvida do hormônio em cada solo por agitação e em repouso. Na adsorção em repouso, os resultados mostraram que o  $Q_{eq}$  para o solo 1 foi de 0,0387 mg g<sup>-1</sup>, enquanto para o solo 2 foi de 0,0726 mg g<sup>-1</sup>. Apesar dos baixos valores, o solo 2 adsorveu 87,6% mais a 17 $\alpha$ -metiltestosterona que o solo 1.

O solo 2 apresenta maior teor de matéria orgânica (40,31 g dm<sup>-3</sup>) do que o solo 1 (32,83 g dm<sup>-3</sup>) e, segundo Ong *et al.*, (2012), a sorção do hormônio MT é impactada pelo teor de matéria orgânica nos adsorventes. Quanto maior o teor de matéria orgânica, maior o processo de adsorção da 17 $\alpha$ -metiltestosterona.

O sobrenadante no experimento com o solo 2 tem maior condutividade (2,61 mS cm<sup>-1</sup>) que o do solo 1 (0,03 mS cm<sup>-1</sup>). A salinidade do meio aquoso no qual o hormônio se encontra possui correlação com sua adsorção, já que devido ao efeito *salting-out* há o decaimento na solubilidade aquosa da MT de modo que com o aumento na salinidade da solução, a solubilidade do hormônio diminui, permitindo maior adsorção no sedimento (Ong *et al.*, 2012).

O pH do meio se manteve entre 5,49 e 5,82 (com desvio padrão relativo de 2,3%) no solo 1 e entre 5,83 e 5,90 (com desvio padrão relativo de 0,6%) no solo 2 ao longo das seis semanas de observação. Não há evidência de que o pH possa alterar a adsorção em repouso da MT.

Segundo Kim *et al.*, (2007) e Ong *et al.*, (2012), o pH não possui impacto na sorção da MT. Segundo estes autores, os valores de Kd (coeficiente de distribuição) da isoterma entre os pH 5,6 e 7,5 são similares entre si e estatisticamente não significantes.

O ponto isoelétrico (PI) da 17 $\alpha$ -metiltestosterona é 1,7 (Pubchem, 2005), indicando que em pH maior que este valor a molécula do hormônio MT apresenta carga neutra que favorece a adsorção em um meio mais apolar (com maior teor de matéria orgânica) e que tem menor solubilidade em meios mais salinos, efeito este observado neste trabalho.

Na Figura 5 observa-se que o tempo de equilíbrio pelo método dinâmico foi alcançado em 24 h de contato entre a solução do hormônio e os solos. Acima deste tempo (até 27 horas), a adsorção diminui entre 2,5 a 3,3%. O tempo de 24 h foi utilizado nos estudos posteriores.

Diferentemente dos resultados obtidos no estudo da adsorção estática, no método de adsorção dinâmica há o favorecimento das colisões entre adsorvato (17 $\alpha$ -metiltestosterona) e adsorventes (solos) ocorrendo adsorção mais eficiente, além da área de contato disponível do solo aumentar com a agitação favorecendo a interação mais intensa.

Na adsorção dinâmica, o teor de matéria orgânica e a salinidade do meio influenciam pouco no processo, mas partículas de óxidos de Fe presentes nos solos podem se caracterizar como um adsorvente importante. Hu, Liu, Deng, Chea, Luo, Sun, Yang & Yang (2011) estudaram a adsorção de 17 $\alpha$ -metiltestosterona em nanopartículas de Fe<sub>3</sub>O<sub>4</sub> (tamanho entre 40 e 100 nm) e verificaram que o processo de adsorção segue a isoterma de Langmuir e que o Q<sub>eq</sub> máximo é de 7  $\mu\text{g g}^{-1}$  do adsorvente, indicando que óxidos de Ferro podem adsorver quantidades do hormônio MT. Os óxidos de Ferro são comuns nos Latossolos vermelhos, típicos da região de coletas das amostras. No caso deste estudo, o solo 1 tem o maior teor de Fe total com 42,56 mg dm<sup>-3</sup> em sua composição e o solo 2 tem 32,76 mg dm<sup>-3</sup>. No sobrenadante do solo 1, o Fe total em concentração de 1,126 mg L<sup>-1</sup> e o solo 2 em 0,236 mg L<sup>-1</sup>, valores encontrados por TXRF.

Nos estudos de isotermas de adsorção (Figura 6), verificou-se que a capacidade máxima de adsorção do solo 1 é de 0,3615 mg g<sup>-1</sup> e a do solo 2 é de 0,2304 mg g<sup>-1</sup>.

De acordo com a classificação de Giles, Smith & Huitson (1974), tem-se que a isoterma que melhor descreve o conjunto de dados demonstrados na Figura 5 para todos os solos, é isotérmico do tipo L (Langmuir), que se baseia na movimentação das moléculas adsorvidas sobre a superfície do adsorvente, ocorrendo distribuição uniforme e formando monocamada recobrimdo toda a superfície. Já o subgrupo dos materiais adsorventes apresenta-se diferente, no qual o solo 1 é descrito pelo subgrupo 3, descreve o comportamento da adsorção por uma subida após um ponto de inflexão, enquanto o solo 2 é descrito pelo subgrupo 1, em que esta descreve que os sítios ativos que interage com o adsorvato não atingindo assim uma concentração de equilíbrio. Hu *et al.* (2011) também descreveram a isoterma de Langmuir como o modelo que mais se ajusta ao processo de adsorção da 17 $\alpha$ -metiltestosterona em Fe<sub>3</sub>O<sub>4</sub>.

A adsorção do hormônio em relação aos solos 1 e solo 2 apresentam características exotérmicas, pois nas menores temperaturas em que o sistema foi submetido, a adsorção apresentou-se máxima.

Os modelos matemáticos de Langmuir, Freundlich, Temkin e Dubinin-Radushkevich foram aplicados para ajustar a isoterma experimental. A partir dos parâmetros obtidos para cada isoterma (Tabela 2) constatou-se que o modelo de Freundlich mostrou-se mais adequado para o solo 1 e o modelo de Temkin para o solo 2 de acordo com os valores de R<sup>2</sup> mais próximos de 1.

A isoterma de Freundlich é baseada na distribuição logarítmica de sítios ativos, que consistem em tratamento válido quando não há grande interação entre as moléculas de adsorvato. Este modelo expressa também que a adsorção é realizada em múltiplas camadas. O valor de n > 1 indica que a adsorção ocorre de maneira favorável a este adsorvente (Kalavathy, Kathikeyan, Rajgopal & Miranda, 2005).

A isoterma de Temkin leva em consideração as interações entre adsorvente – adsorvato e a uniformidade da distribuição das energias de ligação (Foo & Hameed, 2010). Este modelo prediz que o calor da adsorção das moléculas na camada tende a decrescer de forma linear e não logarítmica, aumentando a cobertura do adsorvente (Aharoni & Ungarish, 1977).

A Isoterma de Dubinin é utilizada para discernir se o processo de adsorção é de natureza física ou química, sendo que o

parâmetro que descreve este comportamento é o  $E$  (energia de ligação entre adsorvato-adsorvente). O valor de  $E$  de 1 a 8 indica adsorção física e  $E > 8$  indica adsorção química. Este modelo descreve que a vizinhança da superfície do adsorvente é caracterizada por uma série de equipotenciais superficiais tendo o mesmo potencial de sorção. Esta não assume que a superfície está homogênea ou energia potencial constante (Özcan, Özcan, Tunali, Akan & Kiran, 2005; Chen, Yang, Chen, Chen & Chen, 2009).

#### 4. CONCLUSÕES:

Para os Latossolos estudados, verificou-se que estes podem adsorver o hormônio  $17\alpha$ -metiltestosterona, seja em processo estático (repouso) ou dinâmico (agitação). Maiores teores de matéria orgânica no solo e maior salinidade no meio aquoso influenciam a adsorção por método estático, mas não são importantes pelo processo dinâmico, no qual teores de óxidos de Fe tendem a aumentar a adsorção do hormônio. O equilíbrio de adsorção é atingido em 24 horas e o modelo de Freundlich para o solo 1 e o modelo de Temkin para o solo 2 são os que mais se adequam ao processo de adsorção.

A interação entre o hormônio e solos tropicais ainda é pouco explorado e mostrou que este hormônio pode se alocar em sedimentos, permanecer adsorvido e ser liberado lentamente para o corpo d'água, causando a contaminação deste recurso. Este estudo mostra também a necessidade de mais estudos na área da piscicultura no que tange a utilização de  $17\alpha$ -metiltestosterona.

#### 5. AGRADECIMENTOS:

Ao Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPQ), ao Programa Institucional de Bolsas de Iniciação Científica (PIBIC) e a Fundação Araucária.

**RESUMO**

O aprendizado da química no século XXI deve enfatizar não apenas os resultados da aprendizagem cognitiva, mas também as habilidades metacognitivas e de resolução de problemas. O metacognitivo precisa ser aprimorado para que os alunos possam praticar a organização, o monitoramento e a avaliação do processo de raciocínio na solução de problemas químicos. É necessário desenvolver a solução de problemas para treinar o aluno a tomar decisões e explicações científicas apropriadas ao encontrar problemas químicos. Com base no resultado da observação, as habilidades metacognitivas e de resolução de problemas de professores de ciências em treinamento em Malang, na Indonésia, foram baixas. As habilidades metacognitivas e de resolução de problemas são afetadas pelo aprendizado acadêmico auto-regulado (ASRL) dos alunos. O objetivo deste estudo foi conhecer o efeito da Estratégia Atende à Aprendizagem Baseada em Problemas de Tecnologia de Realidade Aumentada (SMART-PBL) e da aprendizagem acadêmica autorregulamentada (ASRL) na melhoria das habilidades metacognitivas e de resolução de problemas na aprendizagem da química. A SMART-PBL foi modificada pela estratégia de aprendizagem baseada em problemas (PBL) que auxiliou a tecnologia de realidade aumentada como mídia visual. Os sujeitos da pesquisa foram 64 professores de ciências em treinamento divididos em classe controle e experimental, respectivamente de 32 alunos. O método de pesquisa foi o delineamento quasi experimental, com fatorial de projeto de grupo de controle não equivalente 2x2. A classe experimental usou SMART-PBL, enquanto a classe controle PBL. O SMART-PBL teve uma influência significativa nas habilidades metacognitivas e de resolução de problemas em comparação com a estratégia PBL. Além disso, a abordagem SMART-PBL não interagiu com o ASRL para melhorar as habilidades metacognitivas e de resolução de problemas. A implementação do SMART-PBL aprimora não apenas as habilidades metacognitivas e de resolução de problemas, mas também desenvolve habilidades criativas e de pensamento crítico, comunicação e raciocínio científico que aparecem nos alunos durante o aprendizado de química.

**Palavras-chave:** *habilidade metacognitiva, habilidade para resolver problemas, aprendizado baseado em problemas, realidade aumentada, ensino de química.*

**ABSTRACT**

Learning chemistry in the 21st century should emphasize higher-order thinking skills such as metacognitive and problem-solving skills besides cognitive learning outcomes. Metacognitive needs to be improved so students can practice organizing, monitoring, and evaluating their thinking process in solving chemical problems. Problem-solving needs to develop to train students in making the appropriate decision and scientific explanation when encountering chemical issues. Based on observation results, the metacognitive and problem-solving skills of a pre-service science teacher in Malang, Indonesia, were low. Metacognitive and problem-solving skills are affected by academic-self regulated learning (ASRL) by students. This study aimed to know the effect of the Strategy Meets Augmented Reality Technology-using Problem Based Learning (SMART-PBL) and Academic-self regulated learning (ASRL) on improving metacognitive and problem-solving skills in learning chemistry. The SMART-PBL was modified by Problem Based Learning (PBL) strategy, which assisted by Augmented Reality technology as visual media. The research subject was 64 pre-service science teachers divided into control and experimental class, respectively, of 32 students. The research design was Quasi-

Experimental, with Nonequivalent Control Group Design using factorial 2x2. The trial class performed SMART-PBL, which showed a more significant influence on metacognitive and problem-solving skills than the PBL class. The SMART-PBL not interacted with ASRL to improve metacognitive and problem-solving skills. By implementing SMART-PBL improves not only metacognitive and problem-solving skills but also evokes creative and critical thinking, communication, and scientific reasoning skills that appear in students during learning chemistry.

**Keywords:** *metacognitive skill, problem-solving skill, problem-based learning, augmented reality, learning chemistry.*

---

## 1. INTRODUCTION:

Chemistry is a science dimension that tried to explain the occurrence of natural phenomena in the universe scientifically. One of the goals of learning chemistry is building concepts and then using them to solve various natural events in chemistry (Parlan *et al.*, 2018). The idea of chemistry was abstract (Üce and Ceyhan, 2019) and taught in hierarchical manners (Zheng *et al.*, 2017; Armengol and Plaza, 2005). It said to be abstract because it studied real objects which invisible by human vision, for example, the concept of the atom as a constituent of a chemical element. Concepts are arranged in a hierarchy from the basic into the most complex ones consisting of microscopic, symbolic, and macroscopic domains (Jong and Taber, 2007).

Since chemistry concepts were abstract and hierarchy, it considers to be hard to comprehend as a class by students, then the learning process of chemistry has been carried out by teachers with extreme care to prevent misconceptions as were widely reported (Yiin, 2010; Özmen, 2004). So learning activities tend to use a teacher-centered approach. This approach indeed helps students in accelerating in understanding concepts but is not honing their thinking abilities. Whereas higher-order thinking skills such as critical thinking and problem-solving are essential for students in the 21st century (Griffin, Patrick McGraw, 2012).

The most fundamental concept in chemistry was to learn about elements and chemical compounds (Hendry, Robin, 2006; Partington, 1948). This basic concept needs to be master because it studied the atom structure as a constituent of an element, knows the physical and chemical properties, and understands chemical elements' uses before exploring the further complicated concept. When students have mastered the basic concepts, they will find it easier to learn more complex thoughts (Jusniar *et al.*, 2020) to explain the process of occurring natural phenomena caused by the reaction of chemical elements and compounds scientifically.

To explain the process of occurrence of chemical phenomena in daily life, the student needed higher-order thinking skills (HOTS), such as problem-solving skills (Symington, 1977). Developing problem-solving skills required the ability to manage the thinking process, known as the ability to think metacognitive (Jauhangeer, Shuib, and Azizul Hasan, 2018).

Metacognitive is one of the individual thinking skills in managing the process and product of thinking and how to actively monitor and regulate their cognitive processes (Flavell, 1979). Developing metacognitive skills is crucial because it helps identify the level of consciousness, training and tracking this way of thinking, and training on how to solve the problem heuristically (Aurah *et al.*, 2011).

Information about students 'metacognitive knowledge is needed to identify and improve students' thinking patterns in studying chemical material (Parlan, 2019). It supported by research proving that metacognitive skills can help develop problem-solving skills in learning chemistry (Azizah and Nasrudin, 2019). Success in learning chemistry will produce students with analytical thinking skills and scientific attitudes to solve problems scientifically in various situations (Dasna, 2012).

Problem-solving skills also suggested developing in science students while studying chemistry (Stockwell, Stockwell, and Jiang, 2017) due to the fundamental human cognitive processes. The problem occurs when students have no clue how to solve the cases. Problem-solving was a process, consists of systematic observation and critical thinking to find an appropriate solution (Rahman, 2019).

However, based on observations on the research location found several conditions. Besides, low cognitive learning outcomes, apparently new problems were found, metacognitive and problem-solving skills were similar. The level of metacognitive thinking skills was low (51.70%); some students still mistakenly mention the halogen group's chemical elements as noble gas elements. The majority of students

still classify the chemical element of Hydrogen as an alkali metal group. If they had more profound thought about the characteristics of metals, this error would not have occurred. It indicated lower in thinking strategically. This finding supported by a previous study by Ijirana (2018) said that as much as 87% of chemistry educational students had low metacognitive thinking skills.

The level of problem-solving skills was low at (48.07%). Results of interviews with lecturers found that the majority of students still had difficulty explaining scientifically how the reaction of sulfur and other chemical elements can lead to acid rain in industrial and urban areas. This condition was consistent with the findings of Gayon (2003) reported majority high school students have low chemical problem-solving skills. It supported by a similar result by previous studies that science education students have a problem-solving ability that still needs to be improved (Widiasih, 2018).

Based on the results of interviews, students tend to collect assignments lately. It indicates that student's academic self-regulated learning in learning chemistry also found still low. Previous research reported similar findings that only 37% of students used their self-regulated learning ability to predict their performance in general chemistry courses (Miller, 2015).

Based on the explanation above, an effort should be made to develop the ability to think metacognitive and solve problems in pre-service science teachers by improving the quality of the chemistry learning process to provide better learning outcomes.

Previous research published mood for learning chemistry can be built by knowing and linking chemical issues in the history of the invention (Kupatadze, 2018). Improving the quality of learning can be done in several ways, like to empower technology or media in education (Setyosari, 2005). To learn chemistry with complicated and abstract concepts requires media assistance with high abstraction or visualization, such as Augmented Reality technology (AR).

AR was a new technology as well as a field of research sitting at the interface of Virtual Reality (VR), Artificial Intelligence (AI), and Computer Graphics (CG), which the simulated data displayed in a real-world environment. It impacted chemistry for educational purposes and enhanced the illustration of chemical communications (Steven V. Ley, 2016).

The results of a previous study proved that AR could increase interest and motivation to learn chemistry on the learner (Cai, Wang and Chiang, 2014) and help solve chemical problems (Núñez *et al.*, 2008). Besides, the success of AR has widely publicized in improving academic learning outcomes (Efimova, 2012) and chemistry learning outcomes (FS, Irwansyah. Y M, 2018). AR technology cannot be implemented individually in learning. It needed procedural steps in the form of learning strategies (Rosli, 2018). Learners who choose to use a variety of learning strategies tend to earn higher learning outcomes (Simsek, 2010).

(Dewey, 1910) postulated that the thinking process cannot happen suddenly, but can stimulate by presenting a problem, cases, questions, conflict, or confusion about something. Gao *et al.*, (2018) showed his research findings that conceptual understanding and problem-solving skills could improve by implementing learning problem based learning (PBL) strategy. Kamdi (2007) defined PBL as one of the innovative learning models for instructions. PBL famous for using real-world or concrete cases to facilitate learning through a student-centered approach (Salinitri *et al.*, 2015). PBL was modular by Self-Regulated Learning in discovering success. Learners gave responsibility for their learning process and results (Hmelo-Silver, 2004). Academic Self-Regulated Learning (ASRL) affected metacognitive and problem-solving skills. This statement supported by several studies showing the success of self-regulation in solving problems (Ahghar, 2013). The literature states that learners' self-regulation in learning was related to metacognitive skills possessed (Isaacson and Fujita, 2006).

This study implemented the *Strategy Meets Augmented Reality Technology-Using Problem Based Learning* abbreviated as SMART PBL, which integrating Generative and Problem Based Learning (PBL) strategy with Augmented Reality (AR) technology that has successfully developed in the previous study. The difference SMART-PBL from PBL has implemented chemical augmented reality technology as learning media and assignments as a method to explore prior knowledge and build new expertise while solving problems. Modifications added by providing reinforcement of motivation, giving positive perception, constructing knowledge, refining experience, and using knowledge to resolve issues adapted from generative learning theory (Wittrock, 1992).

Several studies have published research about PBL successfully enhanced metacognitive (Pratama, 2018), improved problem-solving skills (Kadir *et al.*, 2016). Generative learning increased problem-solving ability (Wittrock, 1994), increased science comprehension, and self-regulation (Lee, Grabowski and Lim, 2009; Reid and Morrison, 2014).

However, there were no studies yet reported the SMART-PBL learning strategy's success in improving metacognitive thinking and problem-solving skills. Therefore, this study aimed to know the effect of the SMART-PBL learning strategy and academic-self-regulated learning on metacognitive and problem-solving skills in learning chemistry.

## Hypothesis:

This study has six hypotheses:

**H<sub>1</sub>.** There was a significant difference in the metacognitive skill of learners who taught by using the SMART-PBL strategy compared to the PBL strategy.

**H<sub>2</sub>.** There was a significant difference in the metacognitive skill of learners with high ASLR skills and low ASLR skills.

**H<sub>3</sub>.** There was a significant interaction between learning strategies and ASLR's skills to learners' metacognitive skills.

**H<sub>4</sub>.** There was a significant difference in learner's problem-solving skills, which taught using SMART-PBL compared to the PBL strategy.

**H<sub>5</sub>.** There was a significant difference in learner's problem-solving skills with high ASLR skills and low ASLR skills.

**H<sub>6</sub>.** There was a significant interaction between learning strategies and ASLR's skills to learners' problem-solving skills.

## 2. MATERIALS AND METHODS:

### 2.1. Research Design and Samples

This study used a Quasi-experimental design. Following the variables studied, the factorial design used was 2x2 by multivariate analyzes, with Nonequivalent Control Group Design used to play the effect and interaction effect on the dependent variable (Table 1).

The trial class treated using the SMART-PBL strategy with generative assignments, while the control class treated with a PBL strategy

without any task. The research subjects involved 64 pre-service science teachers in Malang, Indonesia, on chemical elements and compounds. All participants have agreed to participate as subject research in each class. Trial and control class each comprised 32 students.

The procedure to implement SMART-PBL learning strategy consists of ten phases namely: (1) attentional focusing and motivational process; (2) problem orientation; (3) student orientation; (4) fact identifications; (5) generate hypothesis; (6) identification knowledge deficiencies; (7); knowledge creation process; (8) generation process; (9) apply new knowledge; (10) abstraction (Figure 1).

### 2.2. Data Collection Tools and Analysis

The statistical test in this study carried out using statistical data processing software in the form of IBM SPSS Statistics 21 using MANOVA parametric analysis. Quantitative data obtained using MAI (*Metacognitive Awareness Inventory*) by Schraw & Denison with a range scale of 1-5. The metacognitive knowledge data obtained using the rubric by Rompayom on a range scale of 0-2. Data on problem-solving skills were collected using the problem-solving rubric by Greenstein on a range scale of 1-4.

## 3. RESULTS AND DISCUSSIONS:

The Shapiro-Wilk's normality test results showed the acquisition of a significant value of metacognitive skills of 0.06 in the experimental class and 0.12 in the control class. The acquisition of the problem-solving skills in the trial class was 0.587, while in the control class was 0.146. The overall value was more significant than the standard criteria ( $\text{sig} > 0.05$ ), so it can conclude that the data distributed. Levene's test showed the acquisition of metacognitive skills of 0.111 and problem-solving skills of 0.596. While the Box's M test was 6.784 with a significance value of 0.709, obtaining all the significance values were more significant than the standard criteria ( $\text{sig} > 0.05$ ), so the data can be said to be homogeneous and come from the same variant, so it is worth to compare.

The hypothesis test performed using; 1) Multivariate analysis to examine the effect of strategy on metacognitive and problem-solving skills simultaneously. This test aimed to assess the significance of the difference in scores between the SMART-PBL group on the metacognitive and problem-solving skills variable

due to the primary influence and interaction between the independent variables. Results showed that each learning strategy's main effect obtains a probability value smaller than the standard criteria (sig)  $0.000 < 0.005$ . The result of ASLR was  $0.705 > 0.005$ , so it concluded that ASLR does not affect metacognitive and problem-solving simultaneously.

After knowing the presence or absence of the influence from each independent variable on the dependent variable, then performed 2) Hypothesis test using a *Test of Between-Subjects Effects* to determine the effect between subjects by testing the comparison between the average scores estimated average and interactive influence analysis in Table 2.

### 3.1. Hypothesis Testing 1

Data results from table 2 showed a significant difference in metacognitive skills among learners taught using SMART-PBL. PBL strategies due to both of the acquisition of significant value were smaller than the standard criteria ( $0.000 < 0.005$ ). The addition of metacognitive awareness scores of students treated using the SMART-PBL strategy increased from 2.58 to 4.18. Whereas in the PBL class, the average value increased from 2.39 to 3.84 (Figure 2). The data analysis results showed that the gain score in the SMART-PBL was 66.04%, with quite a practical interpretation (56-76%). While the PBL class obtained a gain score of 55.37% in the correct interpretation category (40-55%). It concluded that the SMART-PBL strategy was more effective in increasing students' metacognitive awareness than the PBL strategy.

There was a significant difference between before and after implementing the SMART-PBL strategy on the acquisition of an average score of metacognitive knowledge. The increase in the average value of the metacognitive abilities of the trial class from 0.97 to 1.191 while increasing the control class from 0.60 to 1.50 (Figure 3). There was a significant value difference in the aspect of metacognitive knowledge between the SMART-PBL with higher grades than the PBL class. It means the SMART-PBL strategy could increase learners' metacognitive skills more effectively than the PBL strategy.

Several phases on the SMART-PBL strategy contributed to enhancing metacognitive skills for students, that's; **Phase 1**, (Attentional Focusing & Motivational Processes). Before learning begins, students gave generative assignments to draw a mapping concept or to summarize related to the

next meeting material. Tasks were optional according to students' learning preferences to help students collect initial information on these materials (*declarative knowledge*).

This phase was successfully improving student metacognitive skills. The study (Astriani *et al.*, 2020) reported concept mapping applied in the syntax of learning models could improve the metacognitive skills of science students. **Phase 2** (Problem Orientation). Students presented several cases caused by chemical elements in the alkali metal group and others.

At this stage, students practiced thinking about solving problems by identifying what kinds of chemical elements are involved in every case. Students also started practicing metacognitive thinking way by asked themselves how to resolve the issues (*procedural knowledge*). Problems to be solved were products from developing textual concepts became contextual concepts. It could provide a better chemistry learning experience and a positive effect on content comprehension (Silva, Daniele dos Santos; Yamaguchi, 2018).

Some assistance (scaffolding) included in every case. The latest research supports that increasing chemistry learning motivation could use experiments based on concrete evidence (Lima, Alessandra Rodrigues; Silva, Flávia Cristiane Vieira da; Simoes Neto and Euzebio, 2019). Scaffolding also improves metacognitive skills and interest in learning chemistry for learners with a profound understanding of science (Tosun and Senocak, 2013). Cases presented in Table 3.

### 3.2. Hypothesis Testing 2

Data analysis results showed no significant difference in metacognitive skill among learners who had a high level of ASLR and low level of ASLR skills; this was due to the acquisition of considerable value higher than the standard criteria ( $0.690 > 0.005$ ). Results of previous studies showed that there was an effect of one's Self Regulated Learning ability on metacognitive skills. However, in this study, ASRL skills did not significantly influence metacognitive skills. Data in Figure 4 showed learners with a low level of ASRL reached metacognitive value almost equals with high-level ASRL student groups in PBL class. Interestingly, a similar result found by (Nietfeld, 2015) the group with the low academic ability could obtain a higher value of the metacognitive ability (conditional knowledge aspect) than the group with high ones. The high level of ASLR learners described as disciplined and always

active individuals. They have a good strategy in remembering subject matter; a brief target goal should achieve, a structured plan in attaining these goals, and proper evaluation in measuring the progress of learning. They also have a high effort in seeking help for the needs of the learning process either through literature, friends, teachers, and even parents actively, make arrangements or a suitable provision of the learning environment to obtain comfort and focus during learning. They have high priority in completing school assignments and finishing as soon as possible. While the characteristics of groups of students with low ASRL levels are less active in doing these things, it concluded that a high level of ASRL students tended to have higher physical activity in regulating their learning process than the lower level of ASLR students.

The research results from the *Journal of Health Psychology* (Mcelroy, Dickinson and Dickinson, 2015) psychologically explained these findings; they reported that individuals who tend to reduce physical activity appeared to have higher thinking activity. Instead, they were more likely to use this time to think efficiently. They practiced becoming strategic thinkers who can find smart shortcuts to solve problems, save time, and generate innovative ideas. This condition happened to the groups of students with low ASRL capability. They lack physical activity in regulating the learning process, but reportedly high-value metacognitive skill.

Meanwhile, groups of students with high activity (high ASRL) said they were easily bored when they had to sit still and observe their abstract thoughts. Instead, they prefer to stimulate their minds by doing physical activities, such as doing assignments, organizing the study room to be comfortable, making a list of study plans, and other physical activities. The low level of ASRL only indicates the low physical activity in the self-regulation of learning and not as a measure of the low activity (ability) of thinking. It concluded that the low-level ASRL student group had higher thinking skills and was equivalent to the high-level ASRL group. As a result, there was no significant difference between the level of ASRL and metacognitive skills.

### 3.3 Hypothesis Testing 3

The results showed no interaction between SMART-PBL strategy and ASLR skills towards metacognitive skills; this is due to the acquisition of significant value was higher than the standard criteria ( $0,463 > 0,005$ ). These results indicated that the SMART-PBL strategy not

influenced by the ASRL skills of students in improving metacognitive skills. The findings of this study reported that in certain circumstances, SRL also found no effect on the school's academic abilities and learning outcomes (Johny and Magno, 2012). SMART-PBL not affected by ASRL to enhance metacognitive skills; this strategy emphasized training how to know what concepts to learn, how to rearranged thinking ways to solve a problem, and why to choose and use this knowledge and procedures through a series of learning steps that have developed.

### 3.4 Hypothesis Testing 4

The analysis showed a significant difference between student ability to solve problems treated using SMART-PBL and PBL strategy due to the significant value was smaller than the standard criteria ( $0,000 < 0,005$ ). The acquisition of problem-solving skills in the trial class 85.10, with a standard deviation of 1.38 (Figure 5). From the results of the analysis, the ability of the experimental class taught by using the SMART-PBL strategy obtained higher average value than the control class taught by using the PBL strategy.

Several phases in SMART-PBL designed to enhance problem-solving skills in learning, such as **Phase 3** (Students Orientation). A division of the groups has aimed to make students able to solve cases collaboratively. Many advantages if learning sets in teamwork (collaborative) will support sharing knowledge and developing communication skills. Next was **Phase 4** (Facts Identification). Students practiced to identify solutions by looking for facts can be in their prior knowledge or clues that contribute to solving cases. The information obtained at this stage was general and original (authentic) then continued in the next phase. **Phase 5** was (Generate Hypotheses). Students practiced finding the solution of the cases by predicting some of the elements involved in the given problems. In the group, students with the correct hypothesis continued to prove their hypotheses scientifically. Similar things applied to groups with false assumptions. They studied more deeply to find why their predictions cannot be accepted scientifically. At this stage, all students training their conditional knowledge to evaluate the solutions by using their critical thinking and scientific reasoning skills.

**Phase 6** (Identification Knowledge Deficiencies), at this stage, students got a new learning experience. The limited knowledge in

formulating hypotheses completed at this stage. Through the process of searching for information that still needed to build appropriate explanations for solving the problem correctly. Students used mobile Augmented Reality technology in the form of a scanner application to present the desired elements of information. The information displayed is 3D visuals represented the physical form of chemical elements (solid phase, gas phase, liquid phase), atomic number, a symbol of the elements, and the general properties of the elements accompanied by audio when the information is displayed. Data obtained through the interview method as much as 80% of the students like this media, 20% still prefer to use the periodic table element as data collection instruments. These results were similar to research findings, which reported that Augmented Reality could provide an authentic new learning experience (Suartama, Kadek Setyosari, and Ulfa, 2019).

Figures 6 - 9 showed the activities of students when involved with the mobile Augmented Reality. AR technology used in this study took the form of mobile Augmented Reality application using an application on a smartphone equipped with cards containing chemical element information. The mobile Augmented Reality chosen in this study supported by literature, which stated that the form of mobile learning media had a significant impact on learning success due to its ability to take over the role of computers in the speed of accessing information as a learning source (Ulfa, 2013).

**Phase 7, (The Knowledge Creation Processes).** This stage was crucial because students carried out the process of constructing knowledge. (Wittrock, 1992) stated that the knowledge construction process occurs when students manage to connect old information (fundamental knowledge, clues, and hypotheses) that they have with new information obtained. The success of the knowledge construction was if students can explain how to solve the problems and found the chemical elements involved in the case. They analyzed the suitability of new with old information in the form of instructions found. At this stage, students defend solutions by using their creative and critical thinking skills.

**Phase 8 (The Generation Process).** This phase also called the refinement or maturation of knowledge. Students directed to make a categorization or classification of elements been found based on group, nature, and usefulness.

**Phase 9 was (Apply New Knowledge).** This stage

tested the new knowledge that students have about elements and compounds by giving further questions about daily life problems compared to the character of chemical elements found. This phase tested whether students can use their knowledge in solving problems.

**Phase 10 (Abstractions).** Students and lecturers conducted to join evaluations related to chemical elements, and compounds learned on that day. In this last stage, students practiced maintaining their solutions by making deductive or inductive conclusions related to the case resolved. This conclusion makes ensured students had solved the problem correctly, and students have understood the concept thoroughly and anticipated the occurrence of misconceptions.

### 3.5 Hypothesis Testing 5

The analysis showed no significant differences in the problem-solving skill of students who had a high and low level of ASLR due to the acquisition of considerable value that is greater than the standard criteria ( $0,476 > 0,005$ ) (Figure 10). The addition of the ability to solve problems among high and low ASRL student groups had a small difference, so it concluded that there were differences, but otherwise not significant. Several findings reported similar things (Barış, 2018). Research of Nurhayati and Retnowati (2018) found that students with low SRL abilities could solve problems better than the high one. In other words, the high and low level of SRL was not significantly different in solving problems.

SMART-PBL strategy was not depending on how the high-low quality of self-regulation (ASRL) of students will enhance problem-solving skill, and this strategy had phases which designed to improve problem-solving ability. One of them was at the stage of the *Attentional Focusing & Motivational Process*. Pre-meeting assignments must complete before the class meeting; this task optionally gave in the form of making a general description related to the next subject matter could be to draw a concept map or make a summary. The optionally tasks done so that students were more motivated to work on tasks. Summarizing techniques make a significant contribution to students in understanding information, transferring it to long-term memory, and improving memory and knowledge by ensuring practical mental skills (Özdemir, 2018). Wammes, Meade, and Fernandes (2015) found that students who given the task to draw the word (mapping concept) can remember twice as high as those who wrote it. When it completed, unconsciously, students with high and low ASRL levels already have the

same composition of prior knowledge as a knowledge saving in the process of constructing knowledge to help them solve problems during learning. Thus, this explained why students who have high and low ASRL abilities found to have a similar ability to solve problems in this study.

### 3.6 Hypothesis Testing 6

The results showed no interaction between SMART-PBL strategy and ASLR ability to problem-solving skills due to the acquisition of significant value was higher than the standard criteria ( $0.743 > 0.05$ ). ASRL level less considered implementing the SMART-PBL strategy in the future because it was not proven to provide significantly different learning outcomes in solving problems. Following research (F Sulistyowati, B Budiyo, 2017), SRL was not effective in improving problem-solving skills. There was no interaction between SRL on students' mathematical communication and problem-solving abilities. SMART-PBL not influenced by the quality of self-regulation (ASRL) to improve problem-solving skills, but emphasized the process of motivating and focusing the attention of students before starting learning, introducing the content in the form of contextual cases, analyzing cases to collect clues, looking for facts through various learning sources, observing chemical elements in 3D, and learning to formulate hypotheses.

The main results from this study found that; (1) There was a significant difference in metacognitive skills in groups of students who taught using the SMART-PBL and PBL strategies during learning. (2) There was no significant difference in metacognitive skills in students with high ASRL levels and low ASRL levels. Student groups with low ASRL levels provide a higher value of metacognitive skills. (3) There was no significant interaction between learning strategies with ASRL's ability to metacognitive skills. (4) There was a significant difference in problem-solving skills in groups of students who taught using the SMART-PBL and PBL strategies during learning. (5) There was no significant difference in problem-solving skills in groups of students with high ASRL levels and low ASRL levels. (6) There was no significant interaction between learning strategies with ASRL's ability to problem-solving skill.

### 4. CONCLUSIONS:

SMART-PBL learning strategy has successfully improving metacognitive and

problem-solving skills in learning chemistry. Besides developing those skills, SMART-PBL also evokes other higher-order thinking skills such as creative thinking and critical thinking skills. Furthermore, communication skills, scientific reasoning skills, teamwork also appeared in students during solving chemical problems. Problem-solving skills mainly needed critical and creative thinking ability, while scientific reasoning and communication skills required for metacognitive skills.

Metacognitive thinking skills are not affected by academic-self-regulated learning but influenced by the ability; to solve real-world chemical problems; to collect prior knowledge; to identify facts; to build and prove the hypothesis. Similarly, problem-solving skills are also not affected by ASRL skills but by various efforts such as doing collaborative-teamwork, collecting more facts and clues, making hypotheses, finding new information needed, and constructing knowledge, applying new knowledge into real-world life, and concluding a solution.

Chemical augmented Reality (AR) technology can evoke student motivation for learning chemistry; students engaged in meaningful learning with a new learning experience.

a. R Squared = .916 (Adjusted R Squared = .912)

b. R Squared = .928 (Adjusted R Squared = .925)

**R-Square** – This is the proportion of variability in the dependent variable (useful) that can be explained by the model. It is the ratio of the model sum of squares to the total sum of squares.

**Source** – This is the source of the variability in the specified dependent variable.

**Dependent Variable** - This is the variable observed for the effect of treatment on MANOVA.

**Type III SS** – This is a type of sum-of-squares calculation. SS gives the sum of squares that would be obtained for each variable if it were entered last into the model. That is, the effect of each variable is evaluated after all other factors have been accounted for.

**df** – This is the number of degrees of freedom in the model.

**Mean Square** – This is the sum of squares divided by the degrees of freedom.

**F** – This is the approximate F statistic for the given effect and test statistic.

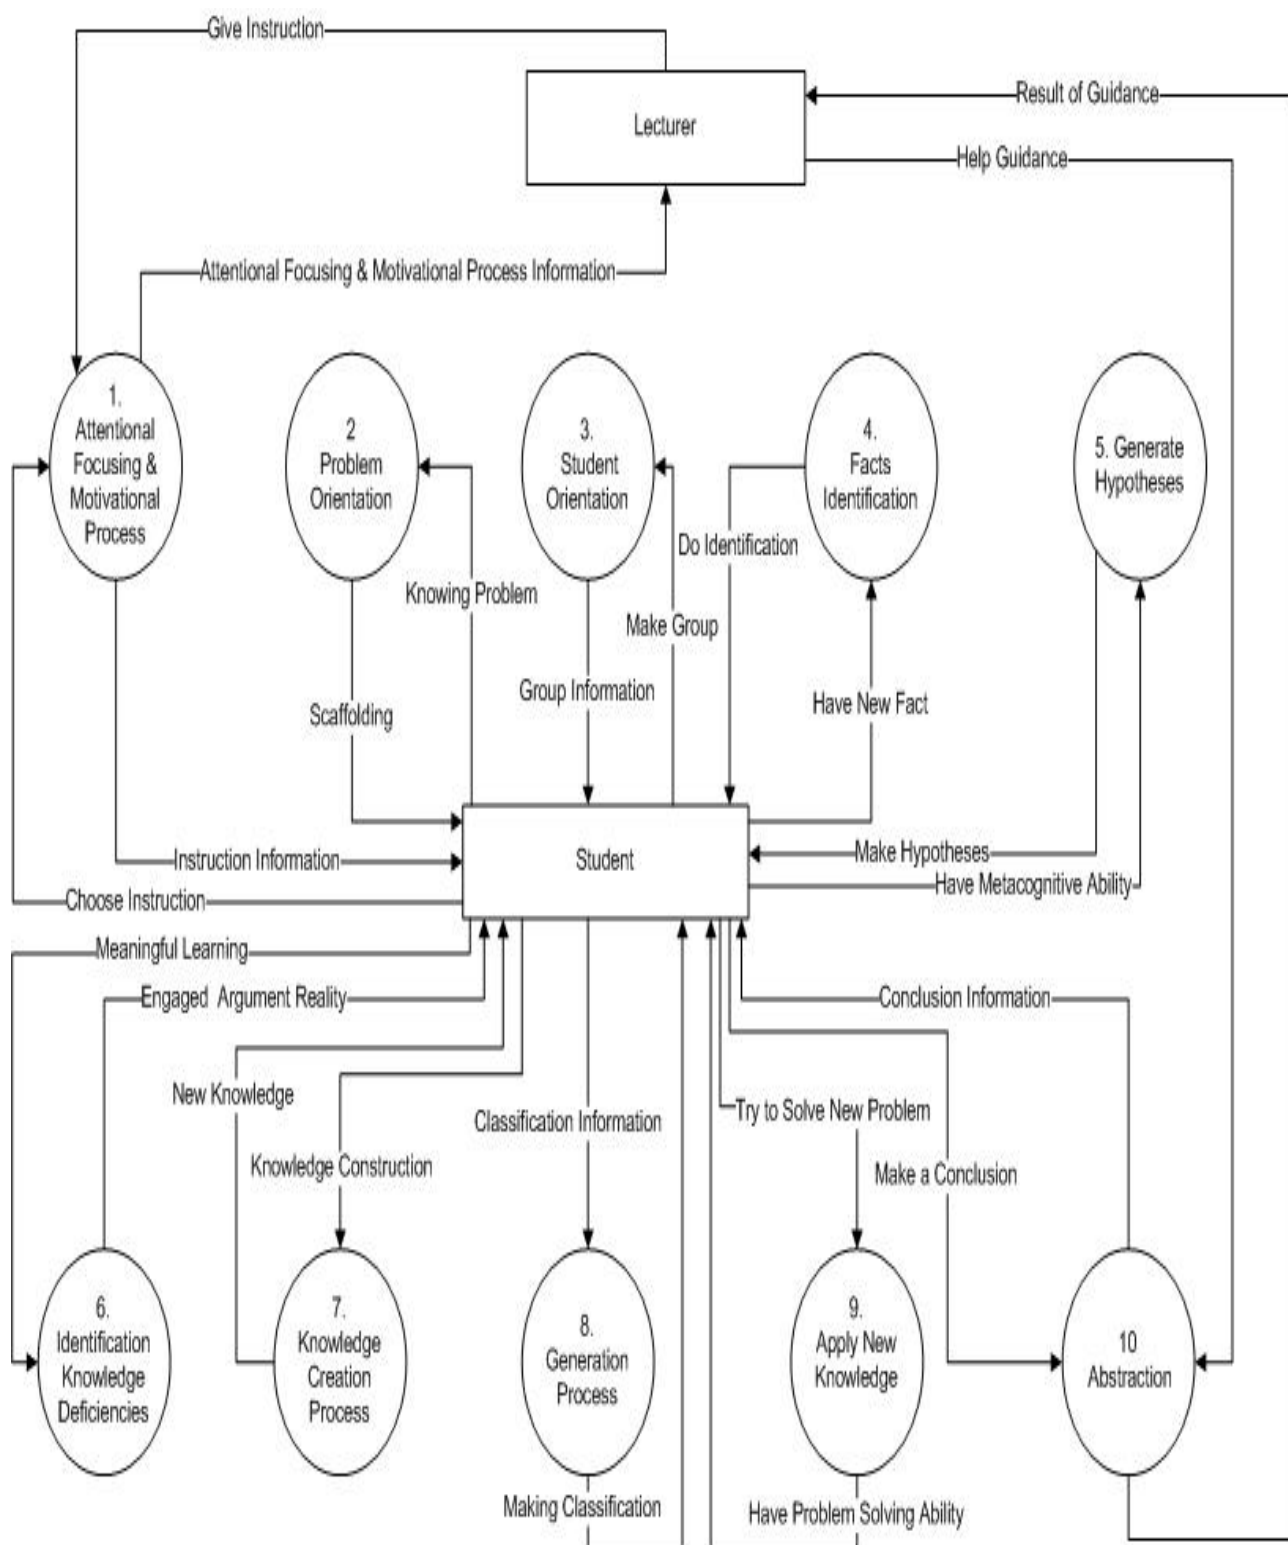

**Sig.** – This is the p-value associated with the F statistic and the hypothesis and error degrees of freedom of a given effect and test statistic. The null hypothesis that a given predictor has no effect on either of the outcomes is evaluated with regard to this p-value. For a given alpha level, if the p-value is less than alpha, the null hypothesis is rejected and accepted  $H_1$ . If not, then we fail to reject the null hypothesis.

**Partial Eta Squared** - The ratio of variance associated with an effect, plus that effect and its associated error variances.

Asterisk (\*) shows signs of interaction between strategy and ASRL. In this study there was no interaction occur due to significant value was higher than 0.005 as standard value (sig.0.463>0.005); (sig.0.743>0.005). as it can be seen in result & discussions of Hypothesis Testing 3 and Hypothesis Testing 6.

**Table 3.** Real-world Chemical Problems as Learning Materials

| No | Real-World Chemical Problems To be Solved  | Chemical Elements Involved That Must Be Found                 | Chemical Elements Concepts To Learn More  |
|----|--|---|---|
| 1  | Investigate the chemical elements in the form of compounds in cooking ingredients that can cause high blood pressure if consumed in excessive amounts.               | Na in the form of Sodium Chloride (NaCl)                      | Sodium (Na): atomic structure, physical properties, and chemical properties                 |
| 2  | Investigate the chemical constituents contained in bananas that can save the brain by preventing blood clots if consumed regularly.                                  | Potassium (K)   | Potassium (K): atomic structure, physical properties, and chemical properties               |
| 3  | Investigate the chemical element known as white fire, which will cause a big explosion if given water—formerly used as a war bomb during World War II.               | Magnesium (Mg)  | Magnesium (Mg): atomic structure, physical properties, and chemical properties              |
| 4  | Investigate the chemical elements in the form of carbonate compounds contained in oyster shells and can produce beach sand into pearls.                              | Calcium in the form of Calcium carbonate (CaCO <sub>3</sub> ) | Calcium (Ca): atomic structure, physical properties, and chemical properties                |
| 5  | Investigate the chemical elements that can nourish human teeth—usually contained in toothpaste at the right levels.  | Fluoride (F <sup>-</sup> )                                    | Fluorine (F <sub>2</sub> ): atomic structure, physical properties, and chemical properties  |
| 6  | Investigate the chemical elements in the gaseous form. World War I used as a yellowish-green colored poisonous gas that could attack the enemy's respiratory system. | Chlorine (Cl <sub>2</sub> )                                   | Chlorine (Cl <sub>2</sub> ): atomic structure, physical properties, and chemical properties |
| 7  | Investigate the chemical elements in seaweed and other seafood, which, if routinely consumed with the right amount, can prevent hyperthyroid disease.                | Iodine (I <sub>2</sub> )                                      | Iodine (I <sub>2</sub> ): atomic structure, physical properties, and chemical properties    |

**RESUMO**

O objetivo do estudo foi examinar a influência dos padrões de comportamento no desenvolvimento de doenças cardiovasculares em diferentes perfis profissionais de pessoas em idade de aposentadoria. Métodos: a base clínica de 500 pensionistas (111 homens e 389 mulheres) ligados a uma das clínicas de Moscou foi usada no estudo. Os documentos médicos foram analisados, a avaliação de especialistas foi realizada, a experiência de vida foi pesquisada e as características comportamentais foram autoavaliadas. A gravidade das doenças cardiovasculares foi tomada como uma variável independente e os perfis profissionais foram utilizados como variáveis adicionais, como segue: perfil realista, perfil convencional e perfil social. Padrões de comportamento foram sendo utilizados como variáveis dependentes. A análise de variância (ANOVA) (um fator e dois fatores) foi usada como método de processamento dos dados. Resultados: maus hábitos (alcoolismo, tabagismo, supernutrição), e agressividade aumentam a gravidade das doenças cardiovasculares entre os aposentados, enquanto a existência de *hobbies* e otimismo diminuem. Nos pensionistas de perfil Realista, os *hobbies* esportivos aumentaram o risco, mas os passa tempos e o bordado diminuíram. Nos aposentados de perfil Social, os hobbies esportivos reduziram ainda mais o risco. Nos aposentados do tipo Convencional, a atividade profissional reduziu o risco, enquanto a presença de uma família, filhos, comunicação e vários hobbies a aumentaram. A supernutrição e a agressividade não produziram um efeito adverso significativo. Conclusão: juntamente com os pré-requisitos comportamentais gerais para a ocorrência de doenças cardiovasculares, os indivíduos dependem do perfil profissional da pessoa. Pesquisas adicionais são necessárias para refinar esses resultados.

**Palavras-chave:** *hábitos comportamentais, hobbies comportamentais, idade da aposentadoria, doenças cardiovasculares, tipos profissionais.*

**ABSTRACT**

The study has been aimed at examining the influence of behavior patterns on the development of cardiovascular diseases in different professional types of retirement-age people. Methods: the clinical base of 500 pensioners (111 men and 389 women) attached to one of the Moscow clinics has been used in the study. Medical documents have been analyzed, the expert assessment has been carried out, the life experience has been surveyed, and behavioral features have been self-assessed. The severity of cardiovascular diseases has been taken as an independent variable, and the professional types have been used as the additional variables as follows: Realistic type, Conventional type, and Social type. Behavior patterns have been used as the dependent variables. Analysis of variance (ANOVA) (one-factor and two-factor) has been used as the data processing method. Results: bad habits (alcoholism, tobacco smoking, overnutrition), aggressiveness increase the severity of cardiovascular diseases among pensioners, whereas the existence of subject hobbies and optimism reduce it. In the pensioners of the Realistic type, sports hobbies have increased the risk, but subject hobbies and needlework reduced it. In the pensioners of the Social type, sports hobbies have further reduced the risk. In the

pensioners of the Conventional type, the professional activity has reduced the risk, whereas the presence of a family, children, communication, and various hobbies have increased it. Overnutrition and aggressiveness have not produced a significant adverse effect. Conclusion: along with general behavioral prerequisites for the occurrence of cardiovascular diseases, individual ones are depending on the person's professional type. Additional research is needed to refine these results.

**Keywords:** *behavioral habits, behavioral hobbies, retirement age, cardiovascular disease, professional types.*

## АННОТАЦИЯ

Цель исследования – изучить, как влияют особенности поведения на развитие сердечно-сосудистых заболеваний у разных профессиональных типов людей пенсионного возраста. Метод: мы использовали клиническую базу пенсионеров, прикрепленных к одной из московских поликлиник – 500 человек (111 мужчин и 389 женщин). Проводился анализ медицинских документов, экспертная оценка, анкетирование жизненного пути и самооценка особенностей поведения. В качестве независимой переменной мы взяли степень сердечно-сосудистых заболеваний, дополнительными переменными являлись: профессиональные типы: Realistic type, Conventional type, Social type. Зависимыми переменными являлись: особенности поведения. Метод обработки данных – дисперсионный анализ ANOVA (однофакторный и двухфакторный). Результаты: степень сердечно-сосудистых заболеваний у пенсионеров увеличивают: вредные привычки (алкоголизм, табакокурение, переедание), агрессивность; снижают: наличие предметных увлечений и оптимизм. У пенсионеров Realistic type усиливали риск: спортивные хобби, а снижали риск предметных хобби и рукоделие. У пенсионеров Social type дополнительно снижало риск наличие спортивных хобби. У пенсионеров – Conventional type снижала риск профессиональная активность, наличие семьи, детей, общения, наличие различных хобби усиливали риск, а переедание и агрессивность не оказывали значимого негативного эффекта. Выводы: наряду с общими, существует индивидуальные поведенческие предпосылки к возникновению сердечно-сосудистых заболеваний, зависящие от профессионального типа человека. Для уточнения этих результатов необходимы дополнительные исследования.

**Ключевые слова:** *поведенческие привычки, поведенческие хобби, пенсионный возраст, сердечно-сосудистые заболевания, профессиональные типы.*

## 1. INTRODUCTION

There are behavioral traits that affect the life expectancy of all people and the development of cardiovascular diseases in them (Berezina and Mansurov, 2015). Such bad habits include alcoholism, tobacco smoking, and overnutrition. The negative effect of bad habits is manifested in all people, regardless of their psychological type or age. At the young age, the risk factors for cardiovascular diseases include excessive weight (20.06 % of cases), tobacco smoking (35.1 % of cases); the adaptive potential of the circulatory system in people with nicotine addiction and those with the excessive weight is significantly lower, systolic hypertension occurs significantly more often (1.5 times), as well as diastolic hypertension (3.1 times) (Ponomareva and Moskalenko, 2016). In the old age, bad habits lead not only to the development of coronary heart disease but also to increase the mortality of heart disease sufferers (Robert *et al.*, 2005).

There are also typological features affecting the development of the cardiovascular disease. Behavioral types with an increased risk of heart disease were identified. The study of M.

Friedman and R. Rosenman is the most famous in this area (Friedman and Rosenman, 1974). Two types of behavior were distinguished in the study: type A – "fight-or-flight" and type B – "hiding". At the same time, the predominance of type A behavior in human life correlates with the risk of cardiovascular disease. Empirical studies confirmed this pattern. In the study, including more than 3,000 people, the authors described the results of an eight-year longitude according to which there were two times more cases of coronary heart disease among the men with the type A personality (Friedman and Rosenman, 1974). In women, type A behavior also contributed to the development of coronary heart disease (Haynes, 1990).

Type A behavior is characteristic of people with the professional Enterprising type, according to John Holland (1973). Such people are set up for competition and success; they feel shortage of time, it is difficult for them to relax, and they become impatient and angry when faced with time delays or with people they consider incompetent. They seem confident, but they are constantly tormented by the feeling of insecurity; they force themselves to do more in less time (Barefoot *et al.*,

1989). It is also known that the psychological traits of a type A patient influence the efficiency of hypertension treatment for some groups of patients (Chumakova *et al.*, 2014).

However, there is no unequivocal evidence of the connection between professional Enterprising type and cardiovascular diseases. Other authors claimed that the features of the emotional sphere rather than the style of professional activity had an influence on the risk of cardiovascular diseases (Spielberger *et al.*, 1985). Moreover, the main factor in the development of cardiovascular diseases was the emotions associated with hostility but not those associated with competition (anger, irritation) (Keith *et al.*, 2017). For example, the 25-year study of 118 male lawyers revealed that those who were more hostile in a law school as per personal questionnaire were more likely to die before the age of 50 years from heart disease than their less-so-hostile fellow students (Barefoot *et al.*, 1989).

Later, another behavioral type – "distressed personality" (D) – was distinguished, which was characterized by a constant intense experience of negative emotions and a tendency to hide them from others because of the fear of being rejected. The representatives of this type are bad-tempered and moody, their attitude to themselves and the world is characterized by constant negativity, they are unable to cope with their negative emotions and cannot share them with other people, which is also considered as a pathogenic factor in the development of cardiovascular diseases (Staniute *et al.*, 2015). It can be noticed that the personal characteristics of such people are opposite to the professional Artistic type according to the John Holland's typology. The representatives of the Artistic type, on the contrary, tend to show their feelings to the whole world. It can be assumed that the risk of cardiovascular disease will be reduced in this type opposite to the "distressed personality" type.

For some other behavioral characteristics, different authors obtained different data. This applies, for example, too optimistic or pessimistic behavior, as well as lifestyle (lonely or with a wide social circle). Some researchers have noted the positive effect of optimism and a wide social circle on the functioning of the cardiovascular system. Researchers at Harvard University demonstrated a positive effect of optimism (Kim *et al.*, 2017). They studied the health data of more than 70 thousand American women of middle and old age that had been obtained as part of mass monitoring among nurses. The researchers found that the most optimistic women had died, on average, 30

% less than their peers and colleagues in a depressed spirit. Also, cancer appeared in them less than usual by 16 %, heart disease – by 38 %, stroke – by 39 %, lung disease, and infection – by 38 % and 52 %, respectively (Kim *et al.*, 2017). There is also evidence of the positive effect of a sense of humor on human health. The 15-year study of life, carried out by Norwegian researchers on 53 thousand participants, showed that the sense of humor was positively related to life expectancy, reduced the risk of death from cardiovascular and infectious diseases in women and the risk of death from infectious diseases in men (Romundstad *et al.*, 2016). Most authors also consider the person's sociability and their wide social circle to be a positive resource. As noted by American researchers, life expectancy is positively related to the frequency of socialization with neighbors, religious participation, and proposal (Cornwell *et al.*, 2008).

Other authors, on the contrary, claim the positive effect of pessimism and a lonely lifestyle. For example, the author of the monumental "The Longevity Project" Lewis Terman and his students, is based on the longitude study that had lasted more than half a century, argued that the pessimism was the key to longevity, whereas the premature death, including that from cardiovascular diseases, was more likely in particularly cheerful and humorous project participants with a wide social circle (Friedman and Martin, 2012). According to their data, hunks and skeptics are more likely to reach older age, since an optimistic view of life often leads to arrogance; optimists lose their sense of prudence: they like to drink, smoke and do not care at all about a healthy diet, and rarely visit doctors (Friedman and Martin, 2012). It turns out that optimists, especially elderly ones, harder bear their misfortune when their optimistic predictions about health turn out to be false. The results of an empirical study of the health status of optimists and pessimists showed that repeated unsatisfied health expectations could undermine motivational resources and accelerate the deterioration of physical condition at the end of life (Hamm *et al.*, 2017).

The authors believe that some of the contradictions of the literature data can be explained by the typological features of a person. Different behavioral factors are favorable for different types of people. In other words, in different types of people, different behavioral patterns can have an effect on the progression of cardiovascular diseases. Professional types are the most important types of mediating the action of

behavioral factors.

The **aim** of the study was the examination of behavioral patterns of different professional types of people (according to Holland's typology), having an effect on the progression of cardiovascular diseases in old age.

**Hypothesis.** The authors have hypothesized that in people engaged in various professional activities during life, various behavioral patterns (hobbies, life path features, attitude to life, and other people) will have an effect on the progression of cardiovascular diseases at the old age. Some behavioral features will be favorable for the specific type of people since they reduce the risk of the disease. Others will be unfavorable for this type and will increase the likelihood of the development of the diseases.

## 2. MATERIALS AND METHODS

### Methods.

1. Analysis of documents. Examination of medical records, medical books, and health certificates. Gender, age, health indicators, and diagnosis were determined based on this.

2. An expert assessment of the severity of diseases by a geriatrician based on clinical trials and data from a medical examination carried out by four experts – neurologist, ophthalmologist, cardiologist, and pulmonologist.

Three levels of severity were distinguished for cardiovascular diseases, as follows: first – low, certain symptoms of cardiovascular pathology were recorded, second – medium, with the history of acute micro-impairments of cerebral or cardiac circulation (first – the second degree of severity), and third – high, cerebrovascular or circulatory disorders of third-degree of severity, third functional class effort angina.

3. Life experience survey. Original development. The subjects were asked to name their profession, level of career achievements, the presence of family and children, religiosity, and to list their interests and hobbies that had taken place throughout life and were preserved. Further, the number of interests and hobbies was calculated in the intellectual, creative, sports, and subject (needlework, hand-made) groups.

4. The Dembo-Rubinstein method of self-assessment of personality characteristics as modified by the authors. The subjects were asked to evaluate personality characteristics, such as activity, aggressiveness, sociability, optimism, and

carefulness (the presence of an object of care). The development of these indicators during life and at the moment was assessed. Subsequently, self-assessment of indicators was reduced to three levels: low, medium, and high.

5. Mathematical statistics methods. One-factor and two-factor Anova (Statistika-12) was used. The severity of cardiovascular disease served as an independent variable. The dependent variables included personality traits and the life paths thereof, namely education, the existence of a family, children, religiosity, number of relocations, continued work at the retirement age, occupation types according to John Holland (Realistic type, Investigative type, Artistic type, Social type, Enterprising type, Conventional type) (Holland, 1973), level of career achievements, bad habits (tobacco smoking, alcoholism, overnutrition), self-assessment of personality characteristics, namely the activity, sociability, optimism, aggressiveness, and carefulness.

6. The professional type served as an additional variable in the two-factor analysis.

**Subjects.** Five hundred retirement-age people, of which 111 men over 60 years of age and 389 women over 55 years of age, all were residents of Moscow, attached to the city polyclinic of the southeastern district and regularly visiting a doctor at least once every two months; 456 subjects were in the medical follow-up due to cardiac disease, and four were not followed-up.

Table 1 presents a detailed gender and age composition of the sample.

## 3. RESULTS AND DISCUSSION

At the first stage, the authors studied how the behavioral characteristics of Russian pensioners influenced the development of cardiovascular diseases in the entire sample. The results are shown in Table 2.

As it follows from the table, all bad habits (alcoholism, tobacco smoking, overnutrition) significantly increase the severity of the cardiovascular diseases at the retirement age, and aggressiveness significantly reduces optimism.

In the second stage, the authors studied the influence of professional types on the progression of cardiovascular diseases (Table 3).

In the third stage, the authors studied the influence of the person's behavioral characteristics on the progression of cardiovascular diseases in the most numerous professional types of the

sample (Realistic type, Social type, and Conventional type).

**Realistic type.** The representatives of this type have higher severity of the cardiovascular disease than all others ( $F(1.494) = 6.7262$ ,  $p = 0.00978$ ).

For the representatives of this type, the authors discovered several additional behavioral patterns. Firstly, it is favorable for them to have substantive hobbies, both during life ( $F(2.494) = 5.4519$ ,  $p = 0.00455$ ) and at the retirement age ( $F(2.494) = 5.0469$ ,  $p = 0.00676$ ). Secondly, the presence of sports hobbies is not favorable for them (at the trend level  $F(4.490) = 2.2382$ ,  $p = 0.06390$ ). See details in Tables 4, 5, and 6.

As it follows from the table, the representatives of the Realistic type with no subject hobbies have the highest severity of cardiovascular diseases. The presence of subject hobbies reduces the severity of the diseases in the representatives of this type (in the table, these are groups 4, 6). For the other types, the presence of subject hobbies is favorable only in relation to the representatives of the Realistic type with no subject hobbies.

As it follows from the table, the same pattern is preserved. The highest severity of cardiovascular disorders was observed in the representatives of the Realistic type with no subject hobbies. The presence of subject hobbies in the representatives of the Realistic type (group 3) significantly reduces the severity of the cardiovascular disorders both in relation to other professional types having such hobbies (group 3) and in relation to their own type with no such hobbies (group 2).

As it follows from the table, the representatives of the Realistic type with many sports hobbies have the highest level of cardiovascular disorders (group 8). It is significantly higher than in many other groups. Also, the presence of sports hobbies significantly increases the severity of cardiovascular disorders in the representatives of the Realistic type (group 6) in relation to other professional types (group 5).

**Social type.** For the representatives of this type, the authors discovered several additional behavioral patterns.

Firstly, it is the link to sex. It is favorable for men to have a profession of the Social type since it reduces the severity of the cardiovascular disorders ( $F(1.496) = 4.7774$ ,  $p = 0.02930$ ). Secondly, for all representatives of the Social type, it is favorable to have sports hobbies throughout

life ( $(4.490) = 2.6221$ ,  $p = 0.03422$ ), and at the retirement age, completeness persists only as a trend. Thirdly, the availability of subject hobbies is not favorable for them at the trend level both during life ( $F(2.494) = 2.5215$ ,  $p = 0.08137$ ) and at the retirement age ( $F(1.495) = 3.3266$ ,  $p = 0.06877$ ). Reliable patterns are presented in Tables 7 and 8.

As it follows from the table, the highest severity of cardiovascular disorders is observed in the men working in other areas (non-Social type) – group 3. In the men of the Social type, the severity of cardiovascular disorders does not differ from that in the women.

As it follows from the table, the representatives of the Social type with one sports hobby (group 4) have lower severity of the cardiovascular disorders than all other groups. It is significantly lower than that of the representatives of other professional types (groups 3 and 6).

**Conventional type.** For the representatives of the Conventional type, the greatest number of patterns was found.

Firstly, for the representatives of the Conventional type, correlation with age is evident. In some age groups, they have lower severity of the cardiovascular disorders ( $F(3.492) = 2.7456$ ,  $p = 0.04249$ ).

Secondly, the existence of a family ( $F(2.494) = 4.4053$ ,  $p = 0.01270$ ), children ( $F(1.496) = 5.1180$ ,  $p = 0.02411$ ), a high level sociability throughout life ( $F(2.494) = 8.9792$ ,  $p = 0.00015$ ) and at the retirement age ( $F(2.494) = 6.8030$ ,  $p = 0.00122$ ) are favorable for the representatives of the Conventional type.

Thirdly, the presence of a variety of hobbies for this type does not have a positive effect. The presence of a large number of intellectual hobbies increases the severity of cardiovascular diseases ( $F(3.492) = 2.8606$ ,  $p = 0.03646$ ). The presence of creative hobbies increases the severity of cardiovascular diseases at the trend level ( $F(1.495) = 3.5924$ ,  $p = 0.05863$ ). In the representatives of this type, the presence of sports hobbies increases the severity of cardiovascular disorders compared to those without sports hobbies ( $F(3.491) = 3.7472$ ,  $p = 0.01106$ ).

Fourthly, some behavioral characteristics harmful to all people are less harmful to the representatives of the Conventional type. For them, the average severity of overnutrition at the retirement age does not have a harmful effect ( $F(2.493) = 3.4019$ ,  $p = 0.03409$ ). Also, a high level

of aggressiveness does not have a harmful effect ( $F(2.494) = 3.3022$ ,  $p = 0.03762$ ) for them.

The most significant differences are shown in Table 9.

As it follows from the table, social characteristics are favorable for the representatives of the Conventional type. The existence of a family, children, and social circle reduces the severity of cardiovascular disorders in the representatives of this type. Also, at the age of 75 – 85 years, cardiovascular diseases are less pronounced in the representatives of this type. A variety of hobbies does not have a positive effect on this type. The presence of intellectual, sports, and creative hobbies does not reduce the severity of cardiovascular disorders. At the same time, some harmful behavioral characteristics (overnutrition, aggressive behavior) do not increase the severity of cardiovascular diseases in the representatives of this type.

In the study, the representatives of the Realistic type, which included all working and technical specialties, turned out to be the most vulnerable to the development of cardiac pathology. In general, both negative professional factors described in the literature affected this group, namely, the work stress associated with increased requirements for work and low ability to influence something, and the imbalance between efforts and rewards. The first one is the demand-control working stress model (by R. Karasek), where the work, which requires great diligence, is the most unfavorable for the cardiovascular system, and at the same time, it has a low decision-making level (Karasek *et al.*, 1998). This applies specifically to the representatives of the Realistic type. This model is supported by the results of the longitudinal study, in which 1,928 working men had been observed for six years, where for the workers performing an unfavorable type of work, the risk of coronary death was six times higher than for the rest (Ushakov *et al.*, 2016).

The second is the effort-reward imbalance model (by J. Siegrist), where the work that requires greater returns and does not give a decent reward is the most dangerous for the development of cardiovascular diseases and atherosclerosis (Siegrist *et al.*, 2004). In summary, the authors emphasize the importance of chronic occupational stress as a factor affecting the development and course of cardiovascular diseases (Gilbert-Quimet *et al.*, 2014), especially if the work is not accompanied by career growth (Berezina and Mansurov, 2015). The professionals related to the

representatives of the Realistic type in the study were also subjected to this type of stress.

However, this study was able to find resource areas that could help the representatives of the Realistic type to reduce the risk of cardiovascular disease. Needlework is positive for this type. Therefore, the psychologists involved in the rehabilitation of retirement-age heart disease sufferers, in this case, recommend developing a person's interests and subject hobbies as a self-help measure. Sports, intellectual and creative hobbies are not associated with the risk of cardiovascular diseases in the representatives of this type. This is mainly because these are mostly the people involved in physical labor, and the positive effect of physical exercises is implemented through labor, and intellectual and creative hobbies are simply expendable.

However, for the representatives of the Social type, which include the representatives of the service sector, teachers, medical workers, a completely different scenario is observed. General psychological patterns (needlework and the development of optimism as the factors reducing the risk of cardiovascular diseases) do not work for them, and it is unlikely that the psychological rehabilitation in this direction will be favorable. However, it should be noted that the level of optimism among employees has been quite high and even slightly above the average for the sample, and it is possible that the positive strength in the representatives of this type has already been involved and an additional increase in optimism would not add anything. To reduce the risk of cardiovascular disease development among the retirees of this group (often leading a sedentary life), it is recommended to practice gymnastics and develop sports hobbies.

For the representatives of the Conventional type, the physical health of a person does not depend on whether he/she is engaged in any hobby or not. For the psychological rehabilitation of workers in this area, it may be effective to turn to their professional activities: continuing to work at the retirement age, acting as an expert or mentor, etc. For the representatives of this type, the resource area is the social one, namely the extension of social circle, increasing the time spent with family and children. In the literature, the presence of kinship at the retirement age is a traditionally favorable factor that reduces the risk of diseases and increases life expectancy (Cornwell *et al.*, 2008). Loneliness is a negative factor since people living alone are less likely to care about their health, and as a result, have a greater risk of developing cardiovascular diseases

and premature death (Jain *et al.*, 2017). The authors have shown that this is true for at least one of the professional types.

#### 4. CONCLUSION

Behavioral factors influence the onset, development, and severity of cardiovascular diseases at the retirement age. Thus, the person's bad habits (alcoholism, smoking, overnutrition), aggressiveness as a personality trait, and a profession related to the Realistic type worsen prognosis, and optimism and the presence of subject hobbies improve it.

Additional positive and negative factors have been discovered for various professional types. In the pensioners of the Realistic type, needlework has a positive effect on the development of substantive interests and hobbies. For the pensioners of the Social type, physical education, sports, and physical activity have a positive effect, whereas optimism and needlework have no effect. For the pensioners who worked with documents – office workers (Conventional type) – engaging in any hobby has no effect, and professional activity and social activity have a positive effect.

**RESUMO**

Os materiais compósitos de carbono-carbono são caracterizados por alta resistência ao calor e estabilidade térmica, para as quais, devido a maioria de suas características físicas e mecânicas, podem ser atribuídos aos materiais mais promissores. Aproximadamente 81% de todos os materiais compósitos de carbono-carbono são utilizados na fabricação de discos de freio para aeronaves, 18% - na tecnologia de foguetes espaciais e apenas 1% - para todas as outras áreas de aplicação. Embora a necessidade de materiais compósitos para tecnologia de foguetes espaciais esteja constantemente diminuindo – o volume de produção de discos de freio para aeronaves está em constante crescimento e, portanto, estudos de propriedades dos materiais compósitos de carbono-carbono sob condições de carga térmica de alta intensidade são extremamente urgentes hoje em dia. Este artigo considera o método para a introdução de silicatos e óxidos nos MCCC, que os endurecem, com a adição de elementos químicos resistentes ao calor. Testes de pontas do MCCC foram realizados sob condições de carga de calor de alta intensidade. Os objetivos do experimento foram obter as formas queimadas do modelo de ponta e registrar a temperatura na superfície durante a ação de um jato que sai do bico do sistema de propulsão. A ponta do MCCC é soprada por meio do sistema de propulsão com um fluxo supersônico de gás contendo oxigênio de alta entalpia. Os resultados de estudos experimentais foram determinados usando gravação de vídeo com base em qual as sequências de quadros foram obtidas. De acordo com os quadros mencionados as formas queimadas foram construídas. Usando medições de imagem térmica, o campo de temperatura na superfície do modelo foi determinado durante todo o tempo em que a superfície do modelo foi exposta ao fluxo de gás supersônico.

**Palavras-chave:** material compósito de carbono-carbono, revestimento com proteção térmica, motor de foguete de propulsão líquida, modelo de ponta, características físicas e mecânicas.

**ABSTRACT**

Carbon-carbon composite materials are characterized by high heat resistance and thermostability for which they, in most of their physical and mechanical characteristics, can be attributed to the most promising

materials. Approximately 81% of all carbon-carbon composite materials are used for the manufacture of brake rotors for aircraft, 18% – in space rocket technology, and only 1% – for all other areas of application. While the need for composites for rocket and space technology is constantly decreasing – the volume of production of brake disc rotors for aircraft is steadily growing, and therefore research on the properties of carbon-carbon composite materials (CCCM) under conditions of high-intensity thermal loading is extremely urgent at the moment. In this paper, we consider a method for introducing silicates and oxides hardening them with the addition of refractory, chemical elements into CCCM. Tests of tips from CCCM were carried out under conditions of high-intensity thermo-force loading. The objectives of the experiment were to obtain scalded forms of the tip model and to record the temperature on the surface during the action of a jet flowing out of the nozzle of the propulsion system (PS). The tip of the CCCM is blown by means of a propulsion system with a supersonic flow of a highly enthalpy oxygen-containing gas. The results of experimental studies were determined using video recording on the basis of which sequences of frames were obtained on the basis of which the burning forms were built. Using thermal imaging measurements, the temperature field on the model surface was determined during the entire time the supersonic gas flow was exposed to it.

## АННОТАЦИЯ

Углерод-углеродные композиционные материалы характеризуются высокой жаропрочностью и термостойкостью, за что их, по большинству своих физико-механических характеристик, можно отнести к наиболее перспективным материалам. Примерно 81% всех углерод-углеродных композиционных материалов используется для производства тормозных дисков для самолетов, 18% – в ракетно-космической технике и только 1% – для всех остальных сфер применения. В то время как потребность в композитах для ракетно-космической техники постоянно снижается – объем производства тормозных дисков для самолетов стабильно растет, в связи с чем исследования свойств УУКМ в условиях высокоинтенсивного термосилового нагружения на сегодняшний момент крайне актуальны. В данной работе рассматривается метод введения в УУКМ упрочняющих их силицидов и оксидов с добавлением тугоплавких химических элементов. Проведены испытания наконечников из (УУКМ) в условиях высокоинтенсивного термосилового нагружения. Целями эксперимента являлось получение обгарных форм модели наконечника и регистрация температуры на поверхности в процессе воздействия на неё струи, истекающей из сопла двигательной установки (ДУ). Наконечник из УУКМ обдувается при помощи двигательной установки сверхзвуковым потоком высокоэнтальпийного кислородосодержащего газа. Результаты экспериментальных исследований определялись с помощью видеорегистрации на основе которой были получены последовательности кадров, на базе которых были построены обгарные формы. С помощью термовизионных измерений определялось поле температур на поверхности модели в течение всего времени воздействия на неё сверхзвукового потока газа.

**Ключевые слова:** *углерод-углеродный конструкционный материал, теплозащитное покрытие, жидкостной ракетный двигатель, модель наконечника, физико-механические характеристики.*

## 1. INTRODUCTION

Carbon-carbon composite materials for most of their physical and mechanical characteristics (FMC) can be attributed to the most promising materials. CCCM are characterized by high heat resistance and thermostability. With intense aerodynamic heating of the thermal protection of hypersonic aircraft, the properties of FMC can change (Bulychev and Kuznetsova, 2019; Ryapukhin *et al.*, 2019; Kozorez and Kruzhkov, 2019; Shen *et al.*, 2019). This is due to the processes of the dynamic interaction of a high-temperature gas flow with the surface of the material. Composite materials of the carbon-carbon system were first created in the early

1960s, simultaneously with the advent of high-strength carbon fibers (Anikin *et al.*, 2019). Obtaining CCCM is based on the principle of heating organic fibers under certain conditions, not destroying them, but turning them into carbon fibers (Kolesnikov *et al.*, 2017; Reznik *et al.*, 2017; Stepashkin *et al.*, 2018). Almost all industrial fibers, as well as a number of specially prepared fibers, were tested as feedstock for these purposes. However, most of them did not meet the requirements, the main of which were the non-meltability or ease of imparting it, the yield of the finished fiber, and its high performance. At the same time CCCM contain a carbon reinforcing element in the form of discrete fibers, continuous filaments, and bundles, as well as various

volumetric frame structures (Song, 2009; Babaytsev *et al.*, 2017; Akhmetzhanov *et al.*, 2018; Yin *et al.*, 2018; Evdokimenkov *et al.*, 2019a; Evdokimenkov *et al.*, 2019b; Formalev *et al.*, 2019; Stepashkin *et al.*, 2019).

The advantage of CCCM is that it is able to perceive various external loads due to the fact that the carbon matrix combines the reinforcing elements in a composite (Mohammed *et al.*, 2019). The properties of CCCM vary over a wide range, and its strength characteristics are especially important (Skvortsov *et al.*, 2014; Orlov *et al.*, 2003). To increase the strength of the composite, carbonization of its polymer matrix is carried out by high-temperature heat treatment in a non-oxidizing medium, and then its graphitization is carried out. It is known that the strength of CCCM based on high-strength carbon fibers is higher than the strength of a composite material based on high-modulus carbon fibers obtained at various processing temperatures. Some CCCM, especially those obtained by carbonizing carbon fiber based on organic polymers, are characterized by an increase in strength with an increase in operating temperature up to 2700 °C. At temperatures above 3000°C, CCCM are efficient for a short time, since intense graphite sublimation begins (Kabanov *et al.*, 2019; Kolotyryn *et al.*, 2019; Radyuk *et al.*, 2019).

Physico-mechanical characteristics of carbon-carbon composite materials are significantly reduced in oxygen-containing environments when exposed to relatively low temperatures (Doretta *et al.*, 2017; Volovik *et al.*, 2018; Piat *et al.*, 2019). Among the special properties of CCCM are low porosity, low coefficient of thermal expansion, maintaining a stable structure and properties, as well as product dimensions. Here, we consider the development of a method for introducing silicides and oxides hardening them with the addition of refractory, chemical elements into the CCCM, which allows us to ensure the functioning of the fired forms of the tip models and to record the temperature on the surface in the process of exposure to a high-enthalpy stream of the oxygen-containing gas.

The mechanical strength of solids is determined by the strength of the interatomic bond. Of the natural bodies, diamond has the highest hardness, in which there are carbon-carbon interatomic bonds. Carbon-carbon bonds are also present in graphite; it has a layered structure. There are strong carbon-carbon bonds inside the layers. These bonds are used to create high strength materials. One of the important problems of creating designs of aviation, aircraft

and rocket engines is the development of new materials used for the manufacture of the most loaded parts operating under high temperatures (Djugum and Sharp, 2017; Wu and Yan, 2018; Wang and Zhu, 2018; Xie *et al.*, 2019).

Carbon-carbon composite materials – a new class of structural materials designed to create heat-loaded, durable, tough products operating in aggressive environments (Chen *et al.*, 2018; Zhang *et al.*, 2019). Products from similar materials are used to create parts for aircraft, rocket devices, and engines. They have a unique ability to maintain high strength and stiffness at temperatures up to 2700 °C, and coating provides performance in an oxidizing environment. Multidimensionally reinforced CCCM are materials based on a carbon matrix and a woven frame of three- or four-dimensional carbon fiber structures. Designed for use in rocketry products operating at high temperatures. It is produced in the form of cylindrical billets and parallelepipeds using serial technologies. Antioxidant coatings are applied to parts operating under high-enthalpy flow products (Mei *et al.*, 2017; Wang *et al.*, 2019). These coatings consist of adhesive and erosion resistant antioxidative layers. The adhesive layer is made on the basis of tantalum carbide, which provides high mechanical bond strength of the erosion-resistant antioxidant coating with CCCM. The main method for testing products is to create conditions as close as possible to the conditions in which the product will work. This is gas-dynamic heat load, creation of an oxidizing environment, vacuum (Davydovich *et al.*, 2017).

## 2. MATERIALS AND METHODS

A tip model made of the composite material was manufactured for the experiment. An antioxidant coating was applied to the tip. Material characteristics are as follows:

- density, 1.67 g / cm<sup>3</sup>;
- porosity 2.5%;
- thermal conductivity 2.6 W / m;
- ultimate tensile stress at 260 MPa;
- tensile modulus 75 MPa;
- breaking stress at compression 140 MPa;
- Poisson's ratio 0.12.

To create a high-temperature free flow from the engine nozzle to the tip on the stand, a liquid rocket engine operating on liquefied oxygen-hydrogen gas is used. The engine using oxygen-

hydrogen fuel in specific impulse is approximately 30% higher than oxygen-kerosene.

The engine consists of a mixing head with pressure jet atomizers, a combustion chamber, and a nozzle. The engine uses a Laval nozzle. It represents a gas channel of a special profile having a narrowing to change the speed of the gas stream passing through it. It is an important part of modern rocket engines. For a video recording of experiments, two video cameras were used, with a recording rate of 30 frames per second, network cable, two opto-digital converters, neutral light filters.

Temperature measurements were made with a thermal imager. Thermal radiation from the surface of the cone passes through the filters and through the lenses of the lens, which forms the image of the cone on the camera matrix. Each matrix element forms a signal proportional to the perceived radiation energy. This signal is digitized and transmitted to the computer via the USB port. On a computer using software, the data is processed, and the thermal radiation of the object is visualized in real-time. Video recording was carried out with a shot breakdown of 30 frames per second, which allowed the construction of combusted forms.

The start of thermal registration was carried out before the start of the experiment. A thermogram was shown on the computer with the maximum tip temperature recorded during the experiment. Thermal registration allowed us to determine the maximum surface temperatures achieved during the experiments. The pressure in the chamber and at the nozzle exit was registered by sensors.

Additional methods using plasmotrons and other equipment were not used.

### 3. RESULTS AND DISCUSSION:

The schematic diagram of the video and thermovisual fixation of the experiment is shown in Figure 1, which shows the overtaking flow coming out from the nozzle of a propulsion system (PS) (1), the investigated model of CCCM (2), a quartz optical window (3), a VideoScan-415 camera (4), a Nikon NIKKOR-52AF lens (5), a filter package consisting of a cut-off filter LP850 and a neutral filter ND8 (6), moreover, objects 4, 5 and 6 together constitute the Tandem VS-415-V2 thermal imager, camera-controller connection 5 m long (7), a laptop with the TERMO-6 thermal imager software installed and data recorded (8), a network cable ~ 60 m long connecting the

recording and controlling laptops (9) located in the control room at a distance of ~ 50 m from the laptop from which control of a laptop connected to a thermal imager is carried out, including data logging control (10).

The video recording complex consists of a laptop, from which data of video cameras are recorded, a network cable-twisted pair (12), with which the laptop was connected to a fiber optic path, which consisted of analog-to-digital converters (13) and fiber itself (14). The cameras (16, 17) were connected to an analog-to-digital converter using network cables-twisted pairs (15). The distance from the cameras and the thermal imager to the model was ~ 4 m. Both devices were located in a separate room next to the stand on an isolated foundation, which allowed to reduce the level of equipment vibration.

Tip models were tested on a bench stand. The bench setup included: an oxygen-hydrogen chamber with a critical section diameter of 92 mm, a holder, an ignition unit, and spark plugs. The model was attached to the stand holder through a spacer. The spacer on the outside was covered with a fairing. The distance of the model from the nozzle exit before testing was  $40 \pm 0.5$  mm.

The duration of the propulsion system in a given mode was 10 s. Samples were measured after testing. The propulsion system worked at the set modes, the temperature at the cut of the chamber was 2780°C, the discharge velocity was 1742 m/s. The objective of the experiment was to obtain scalded forms of the tip model and to register the temperature at the surface during the action of a jet flowing from the remote-controlled nozzle. To achieve these goals, thermal imaging measurements and video recording of the experiment process were carried out as part of the CCCM test program.

The purpose of the video recording is to obtain a sequence of frames on the basis of which the burning forms are built. Using thermal imaging measurements, the temperature field was determined on the model surface during the entire time the jet was exposed to it. The models were a cone with spherical blunting. The half-angle of the cone solution was 7°, and the radius of the spherical blunting was 36 mm. The total length of the model was 125 mm. It should be noted that the models consisted of three parts: the tip of the CCCM material, the stern, and the conical insert along the central axis.

For a video recording of experiments, two video cameras were used. One recorded the general view of the stand during the tests (SONY),

and the second fixed the sample from the angle as close as possible to the thermal imager (JAI), which is designed for non-contact measurement of the temperature of the studied objects. The thermal imager was connected via a communication cable to a PC with the installed VS2001 controller, on which the TERMO 6 software was installed, and on which the obtained thermal images were recorded. PC data management was carried out remotely from the stand control center (Krayushkina *et al.*, 2019).

Thermal radiation from the surface of the object under study passed through the filters and through the lenses of the camera, which forms the image of the object on the CCD matrix of the camera. Each element of the CCD matrix forms a signal proportional to the perceived radiation energy. This signal is digitized and transmitted to the computer via a USB port. On a computer using the TERMO 6 software, the obtained data is processed, and the thermal radiation of the object is visualized in real-time, as well as the reproduction of single thermal images and sequences of thermal images in video mode, as well as a retrospective analysis of the obtained data. It must be clarified that after processing the signal of the TERMO 6 software, a thermogram is formed with temperatures corresponding to the brightness temperature adjusted for the degree of blackness of the test sample (Yuilin *et al.*, 2019).

Further, the term "true temperature" will be used for this temperature. In this case, the actual temperature of objects in some cases may differ from the true temperature recorded by the thermal imager. The video recording was launched by the clock signal received directly from the stand with the following parameters:

- registration speed ~ 6 frames per second;
- degree of blackness – 0.9;
- ambient temperature – 17°C;
- $\lambda$  is the specified coefficient of the medium transmittance (quartz window) – 0.93;
- distance to the sample – 4 m.

The start of thermal registration was carried out manually, before starting. Figure 2 shows a sample before starting. The initial shape of the sample and its position relative to the nozzle are clearly visible. Figure 3 shows a thermogram with temperature decoding. The temperature profile in the "Profile XY" window (3) is calculated along the horizontal line visible on the thermogram (1). In the rectangular region (2), the maximum temperature, the average value, and the number of parameters are calculated. The recorded true

temperature of the gas in the shock layer (6) reaches 1900 °C. In region (6), a jet is seen flowing out of the propulsion system nozzle.

During the experiment, video recording and thermal recording were carried out, which allowed us to construct the diagrams shown in Figure 4 and build the charred forms. Here is a diagram of the distribution of the temperature field ( $T_a$ ) and the flow velocity at the nozzle exit ( $W_a$ ) at different points in time. Figures 5-6 show the appearance of the tip model before and after the test.

As a result of the high-intensity effect of gas-dynamic and thermal loads, the material was carried away from the tip. The ablation of the material largely depends on the heat resistance, heat resistance, and mechanical strength of the tips, which largely depends on the weaving of the fabric, the number of layers of their orientation, epoxy fillers, hardening of products by coating tantalum carbide, silicon. All of the above properties affect the physical and mechanical characteristics. Thanks to video cameras, frames were sequentially obtained on the basis of which rainfed forms were built. Thermal imagers measured the temperature fields on the surface of the tips during the entire time the jet was exposed to them. Tips made of aluminum alloys, stainless steel, titanium could not withstand such loads when conducting similar experiments.

#### 4. CONCLUSIONS:

Therefore, on the basis of the experimental studies carried out in the work, the following data is obtained: experimental dependences of the burning forms of the models on time, data on the distribution of temperature and velocity of the jet outflow on the surface of the models. A diagram of the distribution of the temperature field and the flow velocity as a function of time is shown, from which it can be seen that the jumps in the temperature field are synchronized with the jumps of the velocity vector at times of 3.5 and 5 min. It also illustrated the process of ablation of the mass of the tip when exposed to high-speed high-enthalpy gas flow.

It can be seen from the experimental work that the CCCM retains high heat resistance and heat resistance at high gas-dynamic loads and high temperatures. Experiments have shown that CCCM accepts temperature and gas-dynamic loads due to the fact that the carbon matrix combines the reinforcing elements in CCCM. To increase the strength of CCCM, carbonization of its matrix was carried out, due to which the heat

resistance, heat resistance, erosion resistance of the products were significantly increased.

## 5. ACKNOWLEDGMENTS:

### RESUMO

Com o desenvolvimento da química, substâncias naturais foram ativamente substituídas da vida humana por produtos químicos. No entanto, apesar do enorme progresso nessa área, nas últimas décadas, os problemas de graves efeitos colaterais dos produtos químicos sintéticos no meio ambiente tornam-se cada vez mais pronunciados. Foram utilizados os métodos de cromatografia bidimensional e unidimensional de papel, cromatografia de adsorção em coluna, cromatografia gasosa e espectroscopia de infravermelho. O objetivo do artigo é estudar a composição química da planta de *Linosyris villosa* por métodos físico-químicos de análise e criar formas de dosagem baseadas nela. O problema do artigo é a busca e criação de medicamentos baseados na flora do norte do Cazaquistão. A novidade científica reside no fato de que a composição química e a atividade biológica da planta *Linosyris villosa*, que cresce no território do norte do Cazaquistão, estão sendo estudadas pela primeira vez. De acordo com os resultados da análise, em 13% dos pacientes o efeito do tratamento é insignificante e em 87% dos pacientes houve uma melhoria nas contagens sanguíneas (aumento da hemoglobina, aumento no número de glóbulos vermelhos, quase todos os pacientes retornaram a contagem normal de cores), o número de leucócitos aumentou para normal e a fórmula de leucócitos melhorou. Portanto, o medicamento “Vitin”, que é um extrato de água-álcool da planta *Linosyris villosa*, é um medicamento eficaz para o tratamento de pacientes com anemia de várias gravidades. O significado prático do trabalho é definido da seguinte forma: os compostos biologicamente ativos da planta *Linosyris villosa* foram obtidos com o objetivo de estudá-los e aplicá-los na medicina e na agricultura.

**Palavras-chave:** planta de *Linosyris villosa*, flavonóides, frações de miricetina, filmes de drogas, atividade antianêmica, pesticidas.

### ABSTRACT

With the development of chemistry, natural substances were actively supplanted from human life by chemical products. However, despite the enormous progress in this area, in recent decades, the problems of serious side effects of synthetic chemicals on the environment have become more and more pronounced. Methods of two-dimensional and one-dimensional paper chromatography, column adsorption chromatography, gas chromatography, and IR spectroscopy were used. The purpose of the article is to study the chemical composition of the *Linosyris villosa* plant by physicochemical methods of analysis. Creation of dosage forms based on it. The problem of the article is the search and creation of drugs based on the flora of Northern Kazakhstan. The scientific novelty lies in the fact that the chemical composition and biological activity of the *Linosyris villosa* plant, growing in the territory of Northern Kazakhstan, is being studied for the first time. According to the results of the analysis, in 13% of patients the treatment effect is insignificant, and in 87% of patients there was an improvement in blood values (increase in hemoglobin, an increase in the number of red blood cells, almost

all patients returned color index of blood), the number of white blood cells increased to normal, and the WBC differential improved. Therefore, the drug "Vitin", an aqueous-alcoholic extract of the *Linosyris villosa*, is an effective drug for the treatment of patients with anemia of varying severity. The practical significance of the work is defined as follows: biologically active compounds from the *Linosyris villosa* plant were obtained for the purpose of studying and applying them in medicine and agriculture.

**Keywords:** *Linosyris villosa* plant, flavonoids, myricetin fractions, medicated films, antianemic activity, pesticides.

## АННОТАЦИЯ

С развитием химии, природные вещества активно вытеснялись из жизни человека продуктами химического производства. Однако, несмотря на огромный прогресс в этой области, в последние десятилетия все настоятельнее заявляют о себе проблемы серьезных побочных воздействий синтетических химических препаратов на окружающую среду. Были использованы методы двумерной и одномерной бумажной хроматографии, адсорбционной хроматографии на колонках, газовая хроматография, ИК-спектроскопия. Целью статьи является изучение химического состава растения *Linosyris villosa* физико-химическими методами анализа. Создание на его основе лекарственных форм. Проблемой статьи является поиск и создание лекарственных препаратов на основе флоры Северного Казахстана. Научная новизна заключается в том, что химический состав и биологическая активность растения *Linosyris villosa*, произрастающего на территории Северного Казахстана, изучается впервые. По результатам анализа у 13% больных эффект лечения незначительный, а у 87% больных отмечалось улучшение показателей крови (увеличение гемоглобина прирост количества эритроцитов, почти у всех больных нормализовался цветной показатель крови), увеличилось количество лейкоцитов до нормы, улучшилась лейкоцитарная формула. Следовательно, препарат «Витин», представляющий собой водно-спиртовой экстракт растения *Linosyris villosa*, является эффективным препаратом для лечения больных с анемией различной тяжести. Практическая значимость работы определяется в следующем: получены биологически активные соединения из растения *Linosyris villosa* с целью изучения и применения их в медицине и сельском хозяйстве.

**Ключевые слова:** растение *Linosyris villosa*, флавоноиды, мирицетиновые фракции, лекарственные пленки, антианемическая активность, пестициды.

## 1. INTRODUCTION

A person uses plants not only as food but also as therapeutic agents, as well as in perfumes and as dyes. With the development of chemistry, natural substances were actively supplanted from human life by chemical products. However, despite the enormous progress in this area, in recent decades, the problems of serious side effects of synthetic chemicals on the environment have become more and more pronounced. For example, prolonged use of pesticides in agriculture has caused serious harm to nature and human health (Kumar and Kumar, 2019).

In the field of pharmacology, plants have been the basis for the creation of highly effective medicinal drugs and dietary additives that are used to correct human health. In the field of agriculture, insecticides of new generations, defoliants, attractants, many of which are of plant origin, have been obtained. Active substances from plants are necessary for various fields of industry, as well as promising for use in biotechnology (Fakheri *et al.*, 2011).

The growing amount of information on the diversity of biological activities in plants requires not only an assessment of the role of metabolites in their life and protection against biotic and abiotic stresses but also encourages a comprehensive study of the chemical composition of wild plant species, depending on their habitats. To replenish the assortment of plants, the rigorous and comprehensive studies of the chemical composition and biological properties of individual compounds and phytocomplexes are necessary. The theoretical aspects of the study of secondary plant products as growth regulators, gene expression modulators, and signal transmitters are of great interest. The study of this problem is promising from the point of view of evolutionary transformations of the molecules of secondary compounds and, possibly, the mechanisms of their action on various organisms. According to WHO, the pharmaceutical market in some countries is already 80% represented by plant preparations. Moreover, the production of herbal preparations in the world reaches 60 billion US dollars (WHO traditional..., 2002; Willcox and Bodeker, 2004). Currently, plants containing

flavonoids (biologically active compounds belonging to the class of plant polyphenols) are considered to be the most promising as a source of drug raw materials. Due to the wide variety of their structures and the wide distribution in various plants, flavonoids, and plants containing them are increasingly being studied as a source of phytopreparations in pharmacy (Harborne and Mabry, 1982; Wagner, 1993; Kurkin, 2009; Makarova and Makarov, 2010; Kurkina, 2012; Abdrakhmanova *et al.*, 2019).

Flavonoids belong to natural compounds and are part of many phytopreparations that exhibit specific biological activity of a targeted action (Abhay, 2013; Karak, 2019). Flavonoids in the human body act both on enzyme systems and immune and metabolic processes, causing various effects positive for the body (Hoensch and Oertel, 2015; Panche *et al.*, 2016). Many scientists argue that the diversity of the biological effects of flavonoids is due to their antioxidant activity (Pandey *et al.*, 2010; Kurkin *et al.*, 2013; Mishra *et al.*, 2013). Flavonoids also have antimicrobial, anti-inflammatory, wound healing, vessel-strengthening, antitumoral, antiulcerogenic, and other actions. Flavonoids can be a free radicals scavenger and inhibit lipid peroxidation (Gerdin and Srenso, 1983; Cowan, 1999; Cushnie and Lamb, 2005; Nagendra Prasad *et al.*, 2010; Zandi *et al.*, 2011). Flavonoids as antioxidants play an important role in preventing violations of the structure and functions of the liver in various pathologies, accelerating the regeneration and restoring the functional activity of hepatocytes, especially in the treatment of acute and chronic hepatitis and cirrhosis (Chen *et al.*, 2014; Sánchez-Salgado *et al.*, 2019). The most active were flavonols quercetin and myricetin, which showed high antiviral activity (Kaul *et al.*, 1985; Wu *et al.*, 2008). Currently, flavonoid preparations in the form of various dosage forms are widely used in medical practice: tablets, ointments, tinctures, extracts, powders, dragees, and capsules (Pashtetskiy *et al.*, 2020).

Modern wound coverings include films. The wound covering, as a dressing, must meet the following requirements: create an optimal microenvironment for wound healing, prevent the penetration of microorganisms into the wound, have elasticity, the ability to model surfaces with complex relief, without pyrogenic, antigenic and toxic effects, local irritating and allergic actions. Also, for artificial wound coverings, the following properties are highly desirable: transparency, the ability to observe a wound, the ability to be a drugs

vehicle (antibacterial, reparants), ease of use of films for medical personnel, easy removal of the film from the surface of the skin.

Kazakhstani scientists are also intensively searching for new effective, environmentally friendly medicines based on herbal raw materials. Northern Kazakhstan is the richest region of the medicinal flora habitat, which is represented by *Linosyris villosa*. The chemicals included in the medicinal plant *Linosyris villosa* are currently equally interesting as objects of study in phytochemistry, pharmacy, and medicine (Nazarova *et al.*, 2013; Ramilyeva *et al.*, 2019).

The object of study: *Linosyris villosa*, collected in the flowering phase in Northern Kazakhstan (Korulkin *et al.*, 2007). This is a perennial herbage plant with numerous stems and a horizontal rhizome 30-40 cm high. The leaves are oblong-linear, sessile, whole-cut. The flowers are collected in a cymose inflorescence of yellow color. The plant blooms in late July and early August. *Linosyris villosa* grows in the European part of Russia, Western Siberia, the Caucasus, Ukraine, and Kazakhstan.

The chemical composition of the plant has not been studied. In folk medicine, *Linosyris villosa* is used in the treatment of bronchial asthma, angina pectoris, toothache, and rheumatic pains (Kyusev, 2002). The following dosage forms were obtained based on *Linosyris villosa*: ointment, tinctures, adhesive plasters, which have antidermatitis, anti-inflammatory, and antiseptic effects, so further study of the plant is of extreme interest (Nazarova and Bakumova, 2015; Nevkrytaya *et al.*, 2020).

The problem of the article is the search and creation of drugs based on the flora of Northern Kazakhstan. The scientific novelty lies in the fact that the chemical composition and biological activity of the *Linosyris villosa*, growing in the territory of Northern Kazakhstan, is being studied for the first time. The practical significance of the work is defined as follows: biologically active compounds from the *Linosyris villosa* plant were obtained for the purpose of studying and applying them in medicine and agriculture.

The purpose of the article is to study the chemical composition of the *Linosyris villosa* by physicochemical methods of analysis, as well as the creation of dosage forms based on it.

## 2. MATERIALS AND METHODS

The extraction of biologically active substances from the plant was carried out in a

Soxhlet's apparatus using various solvents (96% aqueous solution, 70% aqueous solution). Extraction was carried out at a temperature of 40 °C for 7 days. Aluminium oxide and nylon as adsorbents were pre-established and used for the separation of flavonoids contained in extracts of the *Linosyris villosa* plant.

Determination of pesticides in alcohol fractions of *Linosyris villosa*. The ECD\_pesticides (HOP).M method was calibrated to detect organochlorine compounds for the following pesticides: hexachlorocyclohexane (HCH) and its isomers: alpha-HCH, beta-HCH, gamma-HCH; 4,4-dichlorodiphenyltrichloroethane (DDT) and its metabolites: 4,4-dichlorodiphenyldichloroethylene (DDE), 4,4-dichlorodiphenyldichloroethane (DDD). The calibration of the pesticide mixture was carried out at 3 levels. Calibration solutions were prepared from standard pesticide samples (pesticide solutions in hexane with a concentration of 100 µg/ml), from which calibration solutions with concentrations of 16.667 µg/ml (level 3), 8.333 µg/ml (level 2) were prepared by sequential dilution 4.167 mcg/ml (level 1). To carry out the calibration,  $5 \cdot 10^{-3}$  cm<sup>3</sup> of the solution was sequentially introduced into the chromatograph evaporator using a microsyringe for each calibration concentration. Each solution was chromatographed twice, calculating the average peak area value of the determined organochlorine pesticide in the chromatogram. The correlation coefficients for the calibration lines for all three concentrations (3 levels) were: 0.99986 for α-HCH, 0.99575 for β-HCH, 0.99942 for γ-HCH, 0.99912 for DDE, 0.99969 for DDD.

The studies were carried out on an Agilent Technologies 7890B GC System gas chromatograph with an electron capture detector (ECD) and a nitrogen phosphorus detector (NPD), on an HP-5 capillary column.

The concentration of residual amounts of organochlorine pesticides, mg/kg, in the analyzed sample, was calculated following the calibration curves. The arithmetic mean value of the results of three parallel determinations was taken as the final analysis result. The discrepancy between the parallel determinations did not exceed the repeatability limit. The repeatability limit for all determining organochlorine pesticides is 20%. The results were considered reliable if the discrepancy between parallel determinations did not exceed the repeatability limit. The repeatability limit for all detectable organochlorine pesticides on a gas chromatograph with an electron-capture and nitrogen-phosphorus

detector is 20% according to the determination method of ST RK 2011-2010 "Water, food, feed and tobacco products. Determination of organochlorine pesticides by chromatographic methods".

The toxicity of polymer films was determined using an AT-05 image toxicity analyzer. This indicator is an alternative to the "local skin irritant action" indicator and does not require the use of experimental animals during testing (Kurkin *et al.*, 2013).

The separation of the substances from the aqueous-alcoholic extract was made using the method of column adsorption chromatography. Aluminum oxide, nylon, and polysorb were used as adsorbents. The best separation results were achieved on nylon and aluminum oxide. On nylon, carbohydrates were separated as related substances, aglycones and glycosides of flavonoid nature were separated.

Aglycones were separated on an aluminum oxide column, in particular, myricetin-containing fractions were obtained. To identify the aglycon, myricetin, it was accumulated, dissolved in 96% alcohol, and rechromatographed on an aluminum oxide column. The resulting eluate was evaporated to dryness and crystallized many times from 80% ethanol in the presence of activated charcoal during which received yellowish crystals with a melting point of 318-320°C. The substance was investigated by two-dimensional paper chromatography in I R<sub>f</sub> = 0.50 and II R<sub>f</sub> = 0.00 systems (Figure 1).

During the study, 4 options for films that differ in composition and production technology were obtained.

**Option 1.** A portion of polyvinyl alcohol (PVA) weighing 1 g was poured into 40 ml of distilled water and left to swell for 24 hours. Then the PVA solution was heated on a tile with an asbestos mesh for 30 minutes. Subsequently, 1 ml of glycerol was added and heated for another 10 minutes. The resulting solution was poured onto a fat extracted base glass lubricated with glycerol. The film dried in 24 hours. The film was thin, transparent, and elastic. The main disadvantage of the film obtained is that it was not well fixed on the skin.

**Option 2.** A portion of PVA weighing 1.25 g was poured into 40 ml of distilled water and left for 24 hours to swell. Then the PVA solution was heated on the tile for 30 minutes. Subsequently, 1 ml of glycerol was added and heated for another 10 minutes. To the obtained carrier, when

heating, 1 ml of alcohol was poured and left to dry. Such a film dried longer than a film obtained from a carrier.

**Option 3.** To the carrier of the film obtained in option 2 was added 1 ml of water while heating. The resulting carrier was poured onto a base glass for drying. The film did not dry for a week. The resulting films did not meet the requirements since their drying time increased in several times.

**Option 4.** The carrier was prepared according to option 1, then, when heated, 2 ml of glycerol was added to the prepared carrier. The resulting solution was poured onto fat extracted base glass, lubricated with glycerol. The film dried in 24 hours. Such a film was thin, transparent, elastic, easily fixed on the skin and did not deform when moving.

Then, the active substance (*Linosyris villosa* extract) was added dropwise to the resulting solution while stirring. The resulting solution was poured onto a fat extracted base glass, lubricated with glycerol. The film dried in 24 hours. The addition of the active substance did not change the properties of the film. The substance was distributed evenly over the entire area of the film. It was concluded that the addition of alcohol and water to the film carrier increased the drying time of the film. Such films do not meet the requirements. The film carrier, with the addition of glycerin and the active substance, meets all the requirements for medicated films and has a prolonged effect (Smiyan *et al.*, 2018).

The test of the obtained films was carried out in an experiment on the skin of patients of the surgical department, after surgical interventions, by such indicators as drying time, film quality, and fixation on the skin (Table 1).

To verify the safety of the obtained medicated film, four aqueous extracts from a polymer film were prepared according to option No. 4, 2 aqueous extracts without an active substance and 2 aqueous extracts with the addition of an active substance with a different concentration, one for each concentration of the active substance (*Linosyris villosa* extract). Previously, it was necessary to evaluate the toxicity of the polymeric material (PVA) used to prepare the films. According to the methodology, an extract from the granules of the polymer material is prepared as follows: the M/V ratio of the PVA granules to distilled water should be 0.1 g per 1 ml of water. For testing, 100 ml of extract was prepared. 10 g of PVA was poured into 150 ml of water and kept in a thermostat at a temperature of 70 °C for 24 hours. After that, the

extract was passed through a paper filter to relieve the swollen PVA. In parallel, the same volume of distilled water was thermostated under the same conditions to obtain a control sample (K).

The obtained extracts were kept in a thermostat at a temperature of 70 °C for 24 hours. In parallel, the same volume of distilled water was thermostated under the same conditions to obtain a control sample (K). The degree of toxicity was determined by comparing the value of the selected test parameter of the test sample (solution) and the value of the same test parameter of the control sample (solution). When determining the toxicity index on the AT-05 image toxicity analyzer, the time-weighted average of the advancement of the sperm suspension was chosen as a test parameter. For the experiment, it was prepared the control and experimental solutions. The experimental solution is prepared from the calculation: 10 ml of aqueous extract, 0.4 g of glucose, 0.1 g of sodium citrate. The control solution is prepared similarly to the experimental one, but instead of the aqueous extract of the polymer film it includes 10 ml of distilled water. After preparation, the control and experimental solutions using a 0.4 ml dispenser were placed in thin section test tubes. The tubes are closed with stoppers and installed in the sample preparation unit (SPU).

The preparation of a uterine sperm suspension was carried out as follows: 1.5 ml of a control solution (solution for sperm thawing) was placed in a test tube using a dispenser. A tube with a solution for thawing is installed in the SPU and warmed up to 40 °C for at least 5 minutes. Then, we removed "straw" with sperm from the Dewar flask using surgical forceps, the end of which is cooled in liquid nitrogen. Holding the straw in the middle with forceps, we cut the polymer packaging on both sides with scissors and place the straw in a test tube. After 10-15 minutes, when the contents of the "straw" completely goes into solution, the tube was shaken several times and returned to its place for further heating. The contents of the tube were warmed for 5-7 minutes and periodically shaken. After that, 0.1 ml of the uterine sperm suspension was added to the tubes with control and experimental solutions using a dispenser. The contents of each tube were mixed. After thorough mixing, the capillaries of the device were filled with work solutions.

The capillaries were filled as follows: the capillary was taken in the right hand so as not to touch the central part of the working surface of the

capillary. The forefinger of the right-hand clamps the end of the capillary and dip the opposite end into a test tube with a work solution with cells to a depth of at least 5 mm. Then the clamped end of the capillary was released. Due to the capillary effect, the solution fills the capillary. The filling process is monitored visually. The capillary is removed from the tube, the wet end is wiped with dry gauze, and the capillary is placed in the carriage at the appropriate position. The carriage is closed with a lid and placed in the analyzer block. 5 capillaries filled with a control sample and 5 capillaries of a test sample were placed in the analyzer unit. 5 cycles of measurements were carried out. The toxicity index was calculated according to the following formula (Equation 1), where  $I_t$  is the toxicity index,  $t_{tw}^o$ ,  $t_{tw}^k$ , are the time-weighted averages of the mobility time of the sperm suspension in experimental and control capillaries with solutions, respectively.

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study.

### 3. RESULTS AND DISCUSSION:

#### 3.1. Obtaining myricetin fractions from the *Linosyris villosa* plant

The object of study was the *Linosyris villosa* plant, the aerial part of which was collected in Northern Kazakhstan during the flowering phase. The moisture content of the raw materials is 8.10%, the ash content is 4.45%. The number of extractives, depending on the type of solvent, is presented in Table 2. Subsequently, to obtain extractives, 70% ethanol was used as the best extraction solvent for the *Linosyris villosa* plant, according to the results of Table 2. In order to establish the composition of the aqueous-alcoholic extract, a qualitative analysis was carried out using specific reagents (Table 3).

Analyzing the results presented in Table 3, it should be concluded that flavonoids are contained in all extracts obtained from the *Linosyris villosa* plant. In the interaction of ammonia vapors with the extract, a yellow color develops, indicating the presence of flavonoids in the extract, the molecule of which contains a carbonyl group that reacts with ammonia to form yellow imines. When the extract interacts with an

alcoholic solution of aluminum chloride, yellow color forms, indicating the presence of flavonoids containing hydroxyl groups in 3 and 5 positions, due to which complex compounds colored in yellow forms. As a result of the interaction of a 1% aqueous solution of lead acetate with the extract, an orange-yellow precipitate forms, indicating the presence of flavones and flavanols in the aqueous-alcoholic extract. During the interaction of a 1% alcohol solution of ninhydrin with the extract, a blue-violet color develops when heated, due to the formation of a blue-violet Ruehmann purpura, indicating the presence of amino acids in the extract. During the interaction of a 1% solution of ferrous ammonium sulfates (FAS) with the extract, green color was observed, and when left to stand, a dark green precipitate formed, indicating the presence of hydrolyzable and condensed tannins in the extract.

Thus, on the basis of qualitative analysis, it can be assumed that the following classes of compounds are present in the extract: flavonoids (flavones, flavonols), tannins, amino acids, carbohydrates, and other compounds. The aqueous-alcoholic extract was also studied by two-dimensional paper chromatography (PC) in systems B:A:W (butanol-acetic acid-water) in the ratio (4:1:5) (I) and 2% acetic acid (II). According to OFS.1.2.1.2.0002.15 "Chromatography on paper", two-dimensional paper chromatography allows us to establish the authenticity, purity, and quantification of the substance sampled involves the sequential passage of the released substances on a sheet of filter paper when moving the mobile phase in two perpendicular directions along the capillaries of the paper, which allows for a clearer separation of the mixture of analytes. Five substances related to flavonoids (aglycones, glycosides), phenolic acids, as well as carbohydrates, amino acids, and traces of tannins were found on the chromatogram.

For aglycon, the IR spectrum was taken in Kbr tablets. In the IR spectrum there were absorption bands in the range of  $1650\text{ cm}^{-1}$  (C=O);  $3450\text{ cm}^{-1}$  (-OH); in the region of in the range of  $2850\text{ cm}^{-1}$ ,  $2940\text{ cm}^{-1}$  (C-H) of the E-ring; in the range of  $1480$ ,  $1520$ ,  $1610\text{ cm}^{-1}$  (C=C) of the E-ring. Thus, on the basis of identification tests, melting point, comparison with myricetin marker, literature data, and IR spectroscopy, the obtained aglycon was identified as myricetin (Figure 2).

#### 3.2. Determination of the toxicity of myricetin fractions produced from the *Lynosyris villosa* on the content of pesticides

To study myricetin fractions, pesticides were selected, which occupy one of the leading positions in terms of hazard and prevalence in the environment. The danger of HCH and its isomers, as well as DDT and its metabolites, is that they are able to persist and accumulate in environmental objects for a long time. And despite the fact that they have not been used for a long time in Kazakhstan, however, they can still be found in environmental objects due to their high persistency.

Determination of pesticides in alcohol fractions of *Linisyris villosa*. The ECD\_pesticides (HOP).M method was calibrated to detect organochlorine compounds for the following pesticides: hexachlorocyclohexane (HCH) and its isomers: alpha-HCH, beta-HCH, gamma-HCH; 4,4-dichlorodiphenyltrichloroethane (DDT) and its metabolites: 4,4-dichlorodiphenyldichloroethylene (DDE), 4,4-dichlorodiphenyldichloroethane (DDD). The studies were carried out on an Agilent Technologies 7890B GC System gas chromatograph with an electron capture detector (ECD) and a nitrogen phosphorus detector (NPD), on an HP-5 capillary column.

According to the results of three parallel studies of myricetin fractions, the organochlorine compounds were not found in the samples; there were no peaks on the chromatogram corresponding to the determined pesticides (Figure 3).

### 3.3. Study of the safety parameters of medicated films based on the *Linisyris villosa* plant

The specified interval of the toxicity index is  $70 < I_t < 120$ . Belonging to this specified interval allows the tested products to be considered non-toxic. The boundaries of the interval are established on the basis of the analysis of the results of parallel tests on animals and on the semen of a bull, which made it possible to find a range where the toxic effect is not found in animal tests. The results of the analysis of the PVA toxicity are presented in Table 4.

Calculation of the toxicity index for PVA polymer material based on the results of 5 cycles (Equation 2). Since the value is  $70 < 84.3 < 120$ , therefore, the polymer material can be considered safe for use and the manufacture of polymer films. Next, the film was prepared according to the recipe of experiment No. 4. We prepared a polymer film and an extract from it: Sample No. 1 ( $O_1$ ) is the polymer film without adding an active substance; Sample No. 2 ( $O_2$ ) is the polymer film with an active substance; Sample No. 3 ( $O_3$ ) is the

polymer film with an active substance, the dose of which is doubled.

An extract for dressings in contact with human skin is prepared as follows: S (area) of the test film is taken to V (volume) of distilled water in ratio 1/1 cm<sup>2</sup>/ml. Moreover, both surfaces of the polymer film are taken into account. To obtain the desired volume, we took 3 samples of a film measuring 10 x 10 cm and filled in a beaker with 200 ml of distilled water. A beaker was covered with a watch glass, and extraction was carried out at a temperature of 40 °C for 7 days. In parallel, the same volume of distilled water was thermostated under the same conditions to obtain a control sample. Samples were taken, and the toxicity index was measured on the 1st, 3rd, and 7th days of extraction. The results of the experiment on the toxicity of polymer extracts after extraction on day 1 are presented in Table 5.

Calculation of the toxicity index for 3 samples according to the results of 5 measurements:  $I_t(O_1) = \frac{185}{226} \times 100\% = 81.9\%$ ,  $I_t(O_2) = \frac{177}{226} \times 100\% = 78.3\%$ ,  $I_t(O_3) = \frac{177}{226} \times 100\% = 78.3\%$ . The results of toxicity after extraction on the 3rd day are presented in Table 6.

Calculation of the toxicity index for 3 samples according to the results of 5 measurements, after 3 days of extraction:  $I_t(O_1) = \frac{255}{315} \times 100\% = 80.9\%$ ,  $I_t(O_2) = \frac{251}{315} \times 100\% = 79.6\%$ ,  $I_t(O_3) = \frac{251}{315} \times 100\% = 79.6\%$ . The results of toxicity after extraction of polymer films extracts for 7 days are presented in Table 7.

The toxicity index was calculated for 3 samples according to the results of 5 measurements, after 7 days of extraction:  $I_t(O_1) = \frac{271}{348} \times 100\% = 77.9\%$ ,  $I_t(O_2) = \frac{271}{348} \times 100\% = 77.9\%$ ,  $I_t(O_3) = \frac{271}{348} \times 100\% = 77.9\%$ . The results showed that PVA-based polymer films with and without the addition of the *Linisyris villosa* extract do not exhibit toxic effects.

### 3.4. Determination of the skin irritant action of medicated films based on the *Linisyris villosa* plant

The skin irritant action of the films was tested in parallel on 3 samples:

– sample No. 1 ( $O_1$ ) is the polymer film

without adding an active substance;

- sample No. 2 (O<sub>2</sub>) is the polymer film with an active substance;

- sample No. 3 (O<sub>3</sub>) is the polymer film with an active substance, the dose of which is doubled.

The action was studied on white mice by immersion of the tails in the extract. The result was compared with a control sample (distilled water). To obtain 1200 ml of the extract, a total of 600 cm<sup>2</sup> of each sample was taken, the film was placed in a beaker covered with a porcelain dish, extraction was carried out at a temperature of 40 °C for ten days. In parallel, the same volume of distilled water was thermostatically controlled under the same conditions to obtain a control sample. Within ten days, samples were taken, and studies were conducted.

White mice were fixed in special cages so that their tails were immersed 2/3 in the solution. The exposure was carried out for 2 hours. The reaction was taken into account immediately after the end of the exposure by the presence of local skin changes (Tables 8-10).

The data showed that the polymer film does not have a skin irritant action and is safe to use.

### 3.5. Study of the drug "VITIN" regarding antianemic activity

The drug "Vitin" obtained by aqueous-alcoholic extraction of the *Linostyris villosa* plant. The following classes of natural compounds were found in the preparation by phytochemical analysis using specific reagents: flavonoids, essential oils, carbohydrates, amino acids, phenolic acids, vitamins, trace elements, and tannins in the form of traces. The drug was studied in the toxicology laboratory "Deri-Dermek" for toxicity, irritating, healing effects, and blood formation. Analysis of the data obtained indicates that Vitin is non-toxic, stimulates the healing process, has an antiseptic effect, and normalizes blood formation.

The effect of the Vitin drug on blood formation was investigated on the basis of a regional hospital on patients in the hematological department during inpatient treatment and during outpatient treatment after the discharge of patients from the hospital. More than 30 patients with anemia and diseases of the internal organs were examined (Table 11).

Studies were performed on 30 patients (22

women and 8 men) aged 17 to 70 years (mean age 40 ± 3.5 years) (Table 12). The patients were divided into 3 groups. Patients of the 1st group took Vitin as a monotherapy, patients of the 2nd group took Vitin in combination therapy with iron preparations. The control group 3 consisted of patients taking iron preparations without Vitin.

Evaluation of the drug effectiveness was carried out after a 2-3 week course of treatment according to the indicators of a complete blood count for two months. Prior to inclusion in the study protocol, at the entrance to its completion, and at the end of the study, all patients underwent a complete blood count to calculate the number of red blood cells and hemoglobin, color index, white blood cell count, and WBC differential. The treatment was stopped when achieving normal blood counts and performance status.

## 4. CONCLUSIONS:

The object of the study was the *Linostyris villosa* plant, collected in the flowering phase in Northern Kazakhstan. To establish the quality of raw materials, pharmacopoeial indicators were determined: humidity (8.10%), ash content (4.45%), and the amount of extractives (16.88%). The optimal flavonoid extractant for the *Linostyris villosa* was experimentally established, which is the aqueous-alcoholic solution (70% ethanol). Using sequential extraction methods and two-dimensional paper chromatography in systems-I (butanol-acetic acid-water) (B:A:W) in a ratio of 4:1:5 and system II (2% acetic acid) the presence of flavonoids in all extracts was observed. Using adsorption chromatography on aluminum oxide, and then distribution chromatography on nylon, a flavonoid aglycone was isolated, the structure of which was proved by physicochemical methods of analysis. Based on qualitative reactions, melting point, comparison with a marker, literature data, and IR spectroscopy, the isolated substance was identified as a flavonoid-based aglycone – myricetin.

The aqueous-alcoholic extract from the *Linostyris villosa* plant was studied for safety by the residual amount of organochlorine pesticides in the extract. There were no pesticides in the studied extract; a conclusion was drawn about the possibility of using plant materials based on *Linostyris villosa* for the manufacture of dosage forms. Polyvinyl alcohol-based medicated films were obtained with the addition of an active substance based on myricetin containing extracts from the *Linostyris villosa* plant. A study of the obtained medicated films for the presence of toxic

and skin irritant actions were conducted. The results showed that polyvinyl alcohol-based polymer films with and without the addition of *Linostyrus villosa* extract did not exhibit toxic effects. The reaction to skin irritant action was zero points (reaction – negative).

The aqueous-alcoholic extract of the *Linostyrus villosa* plant was investigated for the presence of antianemic activity. According to the results of the analysis, in 13% of patients the treatment effect is insignificant, and in 87% of patients there was an improvement in blood values (increase in hemoglobin, an increase in the number of red blood cells, almost all patients returned normal color index), the number of white blood cells increased to normal, and the WBC differential improved. The conclusion was made that the aqueous-alcoholic extract of the *Linostyrus villosa* plant is an effective drug for the treatment of patients with anemia of various severity.

**RESUMO**

O objetivo do estudo foi realizar uma pesquisa de mercado e uma avaliação das preferências do consumidor relacionadas ao uso de aplicativos móveis de saúde (mHealth) na Rússia para apoiar e promover a adesão dos pacientes aos medicamentos. Materiais e métodos. A pesquisa envolveu 1.099 consumidores de saúde móvel de dois segmentos-alvo. O primeiro segmento (S1) incluía consumidores intermediários: real (264 farmacêuticos de 22 regiões da Rússia) e potencial (293 estudantes com especialização em Farmácia). O segundo segmento (S2) incluiu 542 consumidores finais, ou membros do público em geral, de 28 regiões da Rússia. Os estudos de campo foram conduzidos usando os métodos de pesquisa oral (27%) e pesquisa baseada na web (73%) com um questionário estruturado. O método qualitativo com um gráfico de percepção bidimensional e o método quantitativo de estimativas pontuais individuais com o cálculo de indicadores integrais foram utilizados para o posicionamento. Resultados e discussão. O estudo de marketing da adesão a medicamentos revelou que mais de 50% dos entrevistados no S2 têm baixo grau de adesão. As formas mais comuns de apoiar a adesão foram tomar medicamentos como parte da rotina diária normal (87,1%) e usar aplicativos móveis de saúde (66,4%). De acordo com 98,2% dos farmacêuticos e estudantes (S1), os aplicativos mHealth poderiam ser mais amplamente recomendados para uso. As dificuldades técnicas foram a principal barreira para sua implementação (32,5% para o S1 e 59,8% para o S2). Os líderes entre aplicativos móveis para controle de drogas na Rússia foram estabelecidos como resultado do posicionamento usando métodos qualitativos e quantitativos. Foi proposto um mecanismo para promover a saúde móvel, a fim de satisfazer mais plenamente as preferências dos consumidores. Conclusão. Os resultados obtidos fornecem a base para o desenvolvimento de um conjunto de medidas estratégicas para o desenvolvimento adicional do segmento básico do mercado de aplicativos móveis de assistência médica para apoiar a adesão a medicamentos e aumentar as vantagens competitivas do mHealth, que contribuirão para o tratamento eficaz e prevenção de doenças crônicas na Rússia.

**ABSTRACT**

The goal of the study is to conduct a market research and an evaluation of the consumer preferences related to the use of mobile healthcare apps (mHealth) in Russia to support and promote patients' adherence to drugs. Materials and methods. The survey involved 1,099 mHealth consumers from two target segments. The first segment (S1) included intermediate consumers: real (264 pharmacists from 22 regions of Russia) and potential (293 students with major in Pharmacy). The second segment (S2) included 542 final consumers, or members of the general public, from 28 regions of Russia. Field studies were conducted using the oral survey (27 %) and web-based survey (73 %) methods with a structured questionnaire. The qualitative method with a two-dimensional perception chart and the quantitative method of individual point estimates with the calculation of integral indicators were used for positioning. Results and discussion. The marketing study of drug adherence has revealed that over 50 % of the respondents in S2 have low degree of adherence. The most common ways to

support adherence were to take medications as part of the normal daily routine (87.1 %) and to use mobile healthcare apps (66.4 %). According to 98.2 % of the pharmacists and students (S1), mHealth apps could be more widely recommended for use. The leaders among mobile apps for drug control in Russia have been established as a result of positioning using qualitative and quantitative methods. A mechanism for promoting mHealth has been proposed in order to more fully satisfy consumer preferences. Conclusion. The obtained results provide the basis for the development of a set of strategic measures for the further development of the basic segment of the mobile healthcare app market to support drug adherence and to increase the competitive advantages of mHealth, which will contribute to the effective treatment and prevention of chronic diseases in Russia.

## АННОТАЦИЯ

Цель – провести маркетинговое исследование и оценку потребительских предпочтений использования мобильных приложений здравоохранения (mHealth) в России для поддержки и продвижения приверженности пациентов к лекарственным препаратам. Материалы и методы. В опросе участвовали 1099 потребителей mHealth из двух целевых сегментов. Первый сегмент (S1) включал промежуточных потребителей: реальных (264 фармацевта из 22 регионов России) и потенциальных (293 студента, обучающихся по направлению подготовки «Фармация»). Ко второму сегменту (S2) были отнесены 542 конечных потребителей, или представителей широкой общественности, из 28 регионов России. Полевые исследования проводили методом устного опроса (27%) и web-опроса (73%) с использованием структурированной анкеты. Позиционирование осуществляли качественным методом с использованием двумерной карты-схемы восприятия и количественным методом индивидуальных балльных оценок с расчетом интегральных показателей. Результаты и обсуждение. Маркетинговое исследование приверженности к лекарственным препаратам показало, что более 50% респондентов сегмента S2 имеют невысокую степень приверженности. Наиболее распространенными способами поддержки приверженности являлись прием лекарств в рамках обычного ежедневного режима (87.1%) и использование мобильных приложений здравоохранения (66.4%). По мнению 98.2% фармацевтов и студентов (сегмент S1) приложения mHealth могли быть более широко рекомендованы к применению. В результате позиционирования качественным и количественным методами были установлены лидеры среди мобильных приложений по контролю приема лекарств в России. Предложен механизм продвижения mHealth с целью более полного удовлетворения потребительских предпочтений. Выводы. Полученные результаты дают основание для разработки комплекса стратегических мероприятий по дальнейшему развитию базового сегмента рынка мобильных приложений здравоохранения для поддержки приверженности к лекарственным препаратам, повышению конкурентных преимуществ mHealth, что будет способствовать эффективному лечению и профилактике хронических заболеваний в России.

**Ключевые слова:** *mHealth, приверженность к лекарственным препаратам, потребительские предпочтения, мобильные приложения, маркетинг.*

## 1. INTRODUCTION

The problem of insufficient patient adherence to therapy is among the most urgent ones in the modern medicine and society. This problem is especially acute in the treatment of chronic diseases that require a long (often lifelong) intake of drugs and compliance with a list of medical recommendations (McCabe *et al.*, 2017; Nikishchenkova and Nikiforov, 2018; Norberg and Gustafsson, 2018; Rosenberg *et al.*, 2020; Salimzadeh *et al.*, 2019; Schinköthe, 2019). It is believed that low adherence is the main reason for reducing the manifested therapeutic effect, it significantly increases the likelihood of complications of the underlying disease, and leads to a decrease in the living standards of patients and to an increase in treatment costs (Babaskin *et al.*, 2019a; Lukina *et al.*, 2017).

Today, there is no single effective strategy for increasing adherence to therapy; no method is absolutely reliable. The most common ways to support patients' adherence to medication regimens are reminder systems, including tips through written notes, diaries, special packages, smart watches, smart patches, and daily routines (Davies *et al.*, 2015; Henriksen *et al.*, 2018; Skrzypecki *et al.*, 2019). The use of mobile healthcare apps has significantly increased for these purposes in recent years (Bachiri *et al.*, 2016; Brzan *et al.*, 2016; Haase *et al.*, 2017; Sharp and O'Sullivan, 2017). According to analysts of Research and Markets and Research2Guidance, the global market for these apps annually increases by 25 % on average (Sydow, 2019). Mobile apps can give consumers a notification about taking a specific drug at a certain time, its dosage, a reminder to purchase a new drug

package, information on its use, and are also able to control physiological parameters (García *et al.*, 2019; Hansen *et al.*, 2018; Helbostad *et al.*, 2017; Hristoforova *et al.*, 2019; Istepanian and Al-Anzi, 2018; Jeffrey *et al.*, 2019; Jogova *et al.*, 2019; Kagen and Garland, 2019; Nikolaou and Lean, 2017; Peake *et al.*, 2018; Mariblanca and Cano de la Cuerda, 2017; Santo and Redfern, 2019; Stubberud and Linde, 2018). However, they are not able to solve such issues as educational barriers and medical literacy of the population. These barriers can be overcome with the support of patients by pharmacists as the most accessible public health workers (Spears *et al.*, 2020). Pharmacists play a key role in integrating mobile apps in this area. New technologies of mobile apps in healthcare can both increase patients' commitment to therapy and improve the pharmacists' work – make it more automated and effective.

It is necessary to focus primarily on meeting the needs of the population in order to successfully advance patient adherence to drugs and increase the competitiveness of mobile healthcare apps. This requires to conduct research on consumer preferences for using mobile apps to control the administration of drugs and the factors that shape these preferences.

The purpose of the study is to conduct a market research and an evaluation of the consumer preferences related to the use of mobile healthcare apps (mHealth) in Russia in order to support and promote patients' adherence to medication regimens.

## 2. MATERIALS AND METHODS

The objects of research were mHealth apps popular in Russia and used for supporting and promoting drug adherence: Course Pill - medicine intakes, Dosecast - Medication Reminder, Med Helper Pill Reminder, Medisafe Pill Reminder, Mr. Pillster - pill reminder, My pill reminder, MyTherapy Pill Reminder, Pill in Time - reminder and drug take schedule, Pill Reminder and Health Tracker, RX2 - Meds and Pill Reminder L.

A descriptive marketing research – a survey involving 1,099 mHealth consumers – was conducted to support and promote drug adherence from two target segments. The first target segment (S1) included intermediate mHealth consumers: real (264 pharmacists from 22 regions of Russia and 235 business entities with various forms of ownership) and potential

(293 students with major in Pharmacy from the I. M. Sechenov First Moscow State Medical University). It is generally accepted in pharmaceutical marketing that the intermediate consumers are persons who prescribe or recommend medicines (doctors or pharmacists, accordingly) (Skorobogatykh *et al.*, 2018; Smith *et al.*, 2002). The second target segment (S2) included 542 mHealth end users, or members of the general public, from 28 regions of Russia. Real and potential mHealth consumers older than 18 who were ready to participate in the survey, with the exception of pharmaceutical workers and medical students, were included in S2. The participation was anonymous and voluntary, and respondents were fully aware of the purpose, nature, potential benefits, and risks of the survey. The study was conducted in accordance with the principles stipulated by the Helsinki Declaration and the ICC/ESOMAR International Code on Market, Opinion and Social Research and Data Analytics (ICC and ESOMAR, 2016). The sample size of each target segment was determined by time and resource constraints.

The field study was carried out in March – June 2019 by the personal oral interview (27.2 %) and web-based survey (72.8 %) methods using a structured questionnaire (Appendix 1). The questionnaire contained 20 questions regarding the characteristics of respondents, their consumer preferences in using mobile apps to support drug adherence, factors that shaped those preferences, and evaluation of the need satisfaction. Some questions were focused only on the S1 or S2 consumers. This was due, for example, to the professional activities of pharmacists (work experience in the specialty) or the training of students (training course). In the questionnaire, such questions were noted with the words: "If you are a pharmaceutical worker ..." or "If you are a representative of the general public ...". A cover letter with information for the survey participants was attached to the questionnaire (Appendix 2). All questionnaires were coded for tracking purposes, the codes were securely stored.

The questionnaire included questions from the Morisky-Green MMAS-4 test (Morisky *et al.*, 1986) for a general evaluation of the survey participants' adherence to medication regimens: "Do you ever forget to take medications?", "Do you sometimes not pay attention to the hours of the drugs administration?", "Do you skip taking medications if you feel well?", "If you feel unwell after taking medications, do you miss the next dose?". Each negative response was rated at one point. The respondents who scored four points

were considered highly adherent to drugs, three points were medium adhered, and two points or less were low adhered.

The Likert scale was used in responses to some questions of the questionnaire: strongly agree, agree, find it difficult to respond, disagree, strongly disagree, and the "option text" field was used to better understand the opinions of the respondents.

A qualitative method with a two-dimensional perception chart (Malhotra and Birks, 1999) and a quantitative method of individual point estimates with the calculation of integral indicators (Babaskin *et al.*, 2018) were used for positioning.

The statistical data processing was performed using the SPSS.Statistics.v17.Multilingual-EQUINOX (SPSS Inc) software. The characteristics of the respondents of the studied target segments were expressed either in absolute and relative values, or in metric units, such as the median, lower (25 %) and upper (75 %) quartiles (IQR), or the mean  $\pm$  standard deviation (SD). Cross tabulations, Mann-Whitney and Kruskal-Wallis tests were used to evaluate differences between the individual groups. The critical level of significance in testing statistical hypotheses in the study was taken equal to 0.05.

### 3. RESULTS AND DISCUSSION

#### 3.1. Characteristics of the survey participants

Women predominated among 557 respondents in S1 (81.5 %). There were 229 women (86.7 %) in the cohort group of specialists in the field of pharmaceutical activity and 225 women (76.8 %) in the group of students. Their average age was  $37.8 \pm 10.2$  years (median was 38, IQR was 29 – 47) and  $21.3 \pm 3.1$  years (median was 21, IQR was 19 – 23), respectively. Of those surveyed in the group of pharmaceutical workers, 166 people had experience in their field of up to ten years (62.9 %) and 98 respondents had ten years of experience or more (37.1 %). The cohort group of students was approximately evenly distributed among the courses of study: 19.5 % for the first year, 20.1 % for the second year, 20.1 % for the third year, 19.8 % for the fourth year, and 20.5 % for the fifth year.

There were 330 women (60.9 %) and 212 men (39.1 %) among the 542 respondents in S2. Their average age corresponded to  $45.1 \pm 11.6$  years (median was 45, IQR was 34 – 56). Without

any prejudice, the survey participants in S2 were divided into age groups: 18 to 40 years old, or "young" (43.0 %); 40 to 60 years old, or "middle-aged", (35.1 %); and 60 years old and older, or "elderly" (21.9 %). According to their social status, most of the respondents in S2 were employees and workers (64.9 %), while pensioners made up only 7.9 %. It must be noted that the workers from other countries (guest workers) made up a small part of the respondent workers – 2.3 %. The predominant number of mHealth consumers in S2 had higher professional education: specialist's degree (26.2 %), master's degree (12.0 %), and bachelor's degree (32.8 %). The share of S2 respondents with secondary vocational education was 22.5 %, the share without professional training was 6.5 %. The majority of participants in the S2 survey had an average monthly income per family member (57.0 %). The ratio of the respondents from various sociodemographic groups in S2 corresponded to the consumer structure of the Russian pharmaceutical market.

#### 3.2. Consumer preferences in supporting the drug adherence

The results of a general evaluation of the survey participants' adherence to medication regimens using the Morisky-Green test indicated that 71.3 % of the respondents from pharmaceutical workers and students (S1) had high degree of drug adherence (Figure 1). This indicator amounted to 46.1 % among the members of the general public (S2). It must be noted that 83.1 % of the participants in the survey in S1 and only 37.1 % of the participants in S2 observed the regimen of taking medications, regardless of their state of health.

Various methods to support patient adherence to drug regimens are currently known. The results of the survey of the respondents in S1 and S2 about the methods that they would use or would recommend to support drug adherence are presented in Table 1.

The survey results indicated that 98.2 % of the respondents in S1 would recommend using mHealth to support and promote drug adherence. This was equally expressed both in the cohort group of pharmaceutical workers and in the group of students ( $p > 0.05$ ). The external devices (smart patches, smart watches) ranked second (67.3 %) with a slight advantage in the preferences of the student cohort group ( $p = 0.047$ ). This was followed by the methods that helped not forget about taking medications: special packaging and observance of the daily routine (42.7 % each),

according to the equivalent opinion of pharmaceutical workers and students ( $p > 0.05$ ).

The respondents in S2 gave their preference for taking medications as part of the usual daily routine (87.1 %). It must be noted that the most common methods of supporting adherence to prescribed treatment regimens among pharmacists and students (S1) were not widely used among the members of the general public (S2). For example, only 25.6 % of the respondents in S2 used external devices (smart patches, smart watches) to control the intake of drugs. mHealth apps were in demand among 66.4 % of the respondents in S2. The rest of the survey participants (33.6 %) were willing to use this method of supporting drug adherence. The young cohort group in S2 was more willing to acquire mobile apps for adherence to drug regimens compared to the middle-aged group ( $p = 0.032$ ) and the elderly one ( $p = 0.017$ ). In this regard, the respondents in S1 were asked to consider whether patients over 40 years old could use mHealth to support drug adherence. The pharmacists suggested that they completely agreed or rather agreed with a positive response (41.7 %), found it difficult to respond (33.3 %), and rather disagreed or completely disagreed (25.0 %). The data obtained suggested the need for mandatory separation of consumers into age groups for acceptance and the ability to use mHealth to support drug adherence. The opinions in the group of students were divided into exactly the opposite. For example, 36.9 % of the respondents strongly agreed or rather agreed with the capabilities of patients over 40 years old to use mobile apps to control the intake of medications, and 36.5 % of the students were more likely to disagree or completely disagree. Moreover, 43.3 % of the students enrolled in the fifth year and 41.4 % of the fourth-year students indicated that middle-aged and elderly patients could use mHealth. This indicator was reduced to 30 % in the students of the first two years ( $p < 0.05$ ). It can be assumed that there are age and educational gaps between the students with major in Pharmacy regarding their opinions on the possibility of using mobile apps by people over 40 years old to support drug adherence.

### 3.3. Barriers to using mobile apps

To identify barriers to using mHealth, the respondents in each segment were asked to answer the following question: "What factors, in your opinion, make it difficult to use mobile apps to control drug intake?". The survey results are presented in Table 2.

It was found that the current and future pharmacists (S1) considered technical difficulties (32.5 %), unreliable information (28.7 %), and limited content (27.5 %) as the main problems for using mHealth. The statements of the members of the general public (S2) were similar. Technical difficulties were a key problem in using mobile apps (59.8 %). This was especially expressed in the cohort of elderly people (72.3 %,  $p < 0.05$ ). It must be noted that the data on the most significant factors in the group of students in S1 were approximately the same: 31.1 % for technical difficulties, and 30.7 % for both unreliable information and insufficient mobile content.

### 3.4. Positioning consumer preferences in using mobile apps (qualitative method)

The consumer preferences in using mHealth were positioned by compiling two-dimensional perception charts according to two indicators: awareness and popularity (Figure 2).

The results indicated that Medisafe Pill Reminder and MyTherapy Pill Reminder apps were the most recognizable and preferred mHealth apps in S1 and S2. Mobile drug control apps were better known in the cohort group of pharmaceutical workers and students (S1) compared with the group of the members of the general public (S2). The opinions of respondents from S1 and S2 were approximately the same by the Popularity indicator. In this regard, the participants in S2 were asked to answer the question of who advised them to acquire a mobile app. The answers were distributed as follows: doctor advice – 19.6 % (mainly from the group of elderly people,  $p < 0.01$ ), pharmaceutical worker advice – 21.8 % (mainly middle-aged and elderly members of the general public,  $p < 0.05$ ), friend advice – 14.0 %, family tradition – 6.4 %, personal experience – 8.1 %, information on the Internet and reference books – 18.5 %, advertising – 11.1 %, and spontaneously – 0.5 %. It can be assumed that the leading position of pharmacists in the promotion of mHealth explains the comparability of the opinions of respondents in S1 and S2 on the popularity of mobile apps to some extent.

It is known that the level of knowledge about products largely depends on the amount of their advertising. In this case, a directly proportional dependence of the awareness and popularity of mobile apps on the level of their advertising was also observed. Although the value of advertising when choosing mHealth was low (11.1 %), according to the survey, the positioning results revealed that effective advertising support

made mobile apps recognizable and preferred by most Russian consumers.

### 3.5. Factors shaping consumer preferences in using mobile apps

Simplicity and ease of use were the main factors shaping consumer preferences in using mHealth for more than 40 % of the survey participants (ranks 11 and 12, Table 3) ( $p > 0.05$ , S1 and S2). Accessibility, reliability, and security of mobile apps were crucial for almost 30 % of the respondents (ranks 9 and 10, Table 3) ( $p > 0.05$ , S1 and S2). The leading factor in acquiring the app was mHealth quality for 10.1 % of the survey participants in S2, the volume of mobile content for 7.6 %, and 6.3 % of the respondents primarily paid attention to the purchase price. The relationship with the attending physician and/or pharmacist, as well as additional monitoring of physiological parameters were decisive when choosing mHealth for 3.1 % and 1.3 % of the consumers in S2, respectively.

### 3.6. Positioning consumer preferences in using mobile apps (quantitative method)

The positioning of consumer preferences in using mHealth using the quantitative method revealed that mobile apps Medisafe Pill Reminder ( $P_n = 4.9$ , S1;  $P_n = 4.8$ , S2), MyTherapy Pill Reminder ( $P_n = 4.8$ , S1;  $P_n = 4.7$ , S2), and Mr. Pillster – pill reminder ( $P_n = 4.7$ , S1;  $P_n = 4.6$ , S2) had higher competitive advantages (Figure 3). The factors that shaped consumer preferences were used as parameters for comparison (Table 3). The evaluation was carried out on a five-point scale. The significance of factors was taken into account when calculating the integral indicators (Table 3).

### 3.7. Overall satisfaction evaluation

The question “Are you satisfied with the use of the mobile app?” was answered by the respondents in S2 as follows: 46.5 % were completely satisfied or rather satisfied, 40.4 % found it difficult to respond, and 13.1 % were rather not satisfied. The young cohort group in S2 was more satisfied with the use of mHealth to control drug intake compared with the middle-aged group ( $p = 0.035$ ) and the elderly one ( $p = 0.022$ ).

When asked whether the respondent would use mHealth apps in the future to support drug adherence, the overwhelming majority of the respondents in S2 (73.4 %) responded “definitely will” and “rather will”, 19.0 % responded “I find it

difficult to respond”, and 7.6 % responded “probably not.” None of the survey participants was “completely dissatisfied” with the use of the mobile app and responded the question as “definitely not” about the future use of mHealth apps.

Despite the successes achieved in medicine in Russia, the main tasks of the treatment and prevention of certain chronic diseases and their complications remain unresolved (Babaskin *et al.*, 2019b; Ministry of Health of Russian Federation, 2020). This is partly due to the low patients' adherence to drugs. For example, more than 50 % of the respondents in S2 in this study had low and medium adherence (Figure 1). The increasing use of mobile healthcare apps can be a way to support and promote drug adherence. According to IMS mHealth, their global market currently exceeds 165 thous. offers, but only 36 apps account for 50 % of the market (Upatov, 2016). Research2Guidance conducted a survey of 5,000 medical app development firms from around the world (R2G, 2017). Only 2 % of the apps have been downloaded one million times or more, while 62 % have less than five thous. downloads. According to this study, only 66.4 % of the respondents in S2 were real consumers of mobile apps, while 33.6 % would like to use mHealth (Table 1). Technical difficulties were the main barrier to the implementation of mobile apps (59.8 %, S2). This factor was also key in the formation of consumer preferences in using mHealth (24.3 %, S2). Inadequate consumer awareness of mobile drug control apps was another constraint (Figure 2). The authors believe that individuals can be educated to use mobile apps in order to solve these problems in promoting adherence to drugs. This is especially relevant for the “elderly” age cohort group. Adherence to drug regimens is a very important problem for the representatives of this group, and the market capacity of this segment should be the largest. However, only 21.9 % of the respondents in this study were targeted mHealth consumers among the people aged 60 or older (S2). Only about 50 % of them were real consumers of apps. Older people can be taught how to use mHealth by pharmacists leading the way in promoting mobile drug control apps (21.8 %). In this regard, a group of pharmaceutical workers (S1) was asked to consider whether they would agree to help educate these people in using mHealth. 72.3 % of the pharmacists responded positively (“strongly agree” and “rather agree”). 75.1% of respondents from the elderly and middle-aged groups, target segment S2, indicated that they “completely agreed” or “rather agreed” to

receive training in using mobile apps to support drug adherence. They indicated that they “strongly agreed” or “rather agreed” to be educated in using mobile apps to support compliance with prescribed treatment regimens. This can be implemented in Russia at the present time as part of the Concept of Active Longevity Policy under development (TASS, 2019). A cohort group of students in S1 was asked to answer the question of whether they wanted to take an elective course at the university in order to increase their knowledge of mobile healthcare apps. In the long run, they could educate real and potential mHealth users to support drug adherence themselves. The positive response was given by 72.3 % of the students in the third to fifth year of study (“strongly agree” and “rather agree”). Junior students (69.0 %) would like to attend such a course in senior years.

#### 4. CONCLUSION:

1. The marketing study of patient adherence to drug regimens in Russia has revealed that more than 50 % of the respondents in S2 had low degree of adherence. The most common ways to support adherence were to take medications as part of the normal daily routine (87.1 %) and to use mobile health apps (66.4 %). According to 98.2 % of the pharmacists and students (S1), mHealth apps could be more widely recommended for use. The main barriers to their implementation were technical difficulties (32.5 % in S1 and 59.8 % in S2), limited mobile content (27.5 % in S1 and 53.9 % in S2), and unreliable information (28.7% in S1 and 50.2% in S2).

2. The factors shaping consumer preferences in using mobile apps have been identified. Convenience and ease of use were of decisive importance for more than 40 % of the survey participants. Accessibility, reliability, and security of mobile apps were preferred by almost 30 % of the respondents. This was followed by the quality of mHealth (10.1 %), the volume of mobile content (7.6 %), the purchase price (6.3 %), etc. The ranking of the factors allowed to calculate their weight and use these data when positioning consumer preferences.

3. The results of positioning consumer preferences in using mHealth apps using the qualitative method have revealed that mobile apps from Medisafe Pill Reminder and MyTherapy Pill Reminder are the most recognizable and preferred. The data obtained were confirmed by the method of quantitative assessment with the calculation of integral indicators. Medisafe Pill

Reminder ( $P_n = 4.9$ , S1;  $P_n = 4.8$ , S2), MyTherapy Pill Reminder ( $P_n = 4.8$ , S1;  $P_n = 4.7$ , S2), and Mr. Pillster – pill reminder ( $P_n = 4.7$ , S1;  $P_n = 4.6$ , S2) were the leaders among mobile apps. A mechanism has been proposed for promoting mobile apps to control drug intake in order to better satisfy consumer preferences.

The obtained results provide the basis for creating a set of strategic measures for the further development of the basic segment of the mobile healthcare app market to support drug adherence and increase the competitive advantages of mHealth, which will contribute to the effective treatment and prevention of chronic diseases in Russia.

**Figure 1.** General evaluation of the respondents' adherence to drug administration in the two target segments

**Figure 2.** Two-dimensional charts of positioning consumer preferences in using mobile apps to support drug adherence among intermediate (S1) and final (S2) consumers in Russia (qualitative method)

Mobile apps: 1 – Medisafe Pill Reminder, 2 – MyTherapy Pill Reminder, 3 – Course Pill – medicine intakes, 4 – RX2 – Meds and Pill Reminder L, 5 – My pill reminder, 6 – Pill Reminder and Health Tracker, 7 – Mr. Pillster – pill reminder, 8 – Pill in Time – reminder and drug take schedule, 9 – Dosecast – Medication Reminder, 10 – Med Helper Pill Reminder

**Figure 3.** Fragment of the chart of positioning the consumer preferences in using mobile apps to support drug adherence among intermediate (S1) and final (S2) consumers in Russia (quantitative method,  $P_n$  is a composite parametric index)

**Table 1.** Consumer preferences in using various methods of supporting drug adherence among intermediate (S1) and final (S2) consumers in Russia

| Methods of supporting drug adherence                       | Share of respondents, % (one or several answer options) |              |
|--|---|--------------|
|  | S1 (n = 557)  | S2 (n = 542) |
| Written reminder or self-monitoring diary                  | 24.1  | 34.5         |
| Normal daily routine                                       | 42.7  | 87.1         |
| Health impairment  | 4.5   | 18.6         |
| Reminders from family members or colleagues                | 13.5  | 10.5         |
| Special packaging for drug control (with or without timer) | 42.7  | 21.0         |
| External devices (smart patches, smart watches)            | 67.3  | 25.6         |
| Mobile apps (mHealth)                                      | 98.2  | 66.4         |
| Phone alarm  | 1.8   | 0.9          |

**Table 2.** Barriers to using mHealth to support drug adherence among intermediate (S1) and final (S2) consumers in Russia

| Barriers to using mHealth to support drug adherence | Share of respondents, % (one or several answer options) |              |
|---|---|--------------|
|   | S1 (n = 557)  | S2 (n = 542) |
| Technical difficulties                              | 32.5  | 59.8         |
| Inadequate security                                 | 24.1  | 30.4         |
| Unreliable information                              | 28.7  | 50.2         |
| High price  | 12.4  | 19.2         |
| Inadequate regulation by professional bodies        | 15.3  | 22.3         |
| Limited mobile content                              | 27.5  | 53.9         |
| Low availability                                    | 15.6  | 16.6         |
| Lack of usability                                   | 8.4   | 11.6         |

## APPENDIX 1. QUESTIONNAIRE

### Dear survey participant!

We are conducting a marketing research of consumer preferences in using mobile healthcare apps (mHealth) to control drug adherence. This will make apps more accessible, convenient and useful.

Please answer the questions below. Choose an answer option (one or more) or specify your own.

#### 1. Your gender:

- ☐ male
- ☐ female

#### 2. Your age: \_\_\_\_\_

#### 3. Your education:

- ☐ without vocational education
- ☐ secondary vocational education
- ☐ incomplete higher education
- ☐ higher education
- ☐ Master's degree
- ☐ Bachelor's degree

#### 4. Your social status:

- ☐ worker
- ☐ worker of other countries (guest worker)
- ☐ employee
- ☐ retiree
- ☐ student
- ☐ housewife
- ☐ temporarily unemployed
- ☐ entrepreneur

#### 5. Your average monthly income per family member:

- ☐ below average
- ☐ average
- ☐ above average

**6. You are:**

- ☐ a pharmaceutical worker
- ☐ a student with major in Pharmacy
- ☐ a representative of the general public

**7. If you are a pharmaceutical worker, then your work experience in the specialty is:**

- ☐ up to 10 years
- ☐ 10 years and more

**8. If you are a student with major in Pharmacy, then your year of study is:**

- ☐ 1
- ☐ 2
- ☐ 3
- ☐ 4
- ☐ 5

**9. Do you ever forget to take medications?**

- ☐ yes
- ☐ no

**10. Do you sometimes not pay attention to the hours of drugs administration?**

- ☐ yes
- ☐ no

**11. Do you skip taking medications if you feel well?**

- ☐ yes
- ☐ no

**12. If you feel unwell after taking medications, do you miss the next dose?**

- ☐ yes
- ☐ no

**13. The method that you use or would recommend for use to control the drug intake:**

- ☐ written reminder or self-control diary
- ☐ normal daily routine
- ☐ poor health
- ☐ reminders from family members or work colleagues
- ☐ special packages for control of drug intake (with or without timer)
- ☐ external devices (smart patches, smart watches)
- ☐ mHealth apps
- ☐ phone alarm

**14. Indicate the popularity degree of the mHealth apps that you use, would like to use or would recommend to use, using the perceptual map:**

- Course Pill – medicine intakes (1)
- Dosecast – Medication Reminder (2)
- Med Helper Pill Reminder (3)
- Medisafe Pill Reminder (4)
- Mr. Pillster – pill reminder (5)
- My pill reminder (6)
- MyTherapy Pill Reminder (7)
- Pill in Time – reminder and drug take schedule (8)
- Pill Reminder and Health Tracker (9)
- RX2 – Meds and Pill Reminder L (10)
- Other \_\_\_\_\_ (11)

**15. How do you think what factors make it difficult to use mHealth apps to control medication intake?**

- ☐ technical difficulties
- ☐ inadequate security
- ☐ unreliable information
- ☐ high cost
- ☐ insufficient regulation by professional bodies
- ☐ limited mobile content
- ☐ low availability
- ☐ lack of usability
- ☐ other \_\_\_\_\_

**16. If you are a representative of general public and use mHealth apps to control drug intake, then who advised you to make a purchase:**

- ☐ advice of a doctor
- ☐ recommendation of a pharmaceutical worker
- ☐ advice of friends
- ☐ tradition in the family
- ☐ personal experience
- ☐ information on the Internet and reference literature

- ☐ advertising
- ☐ spontaneously

**17. If you are a pharmaceutical worker or a student with major in Pharmacy, indicate your opinion. Patients older than 40 years old can use mHealth apps to control medication intake:**

- ☐ totally agree
- ☐ rather agree
- ☐ difficult to answer
- ☐ rather disagree
- ☐ totally disagree

**18. Rank and evaluate (on a five-point scale) the factors that shape your preferences for use or recommendations for using mHealth apps to control drug intake (twelve is the most important factor, one is the least important factor):**

| Factor   | Rank | Mobile app name (mHealth) |  |  |
|--|------|---------------------------|--|--|
|  |      |                           |  |  |
| User-friendliness  |      |                           |  |  |
| Reliability and safety   |      |                           |  |  |
| Availability   |      |                           |  |  |
| Cost   |      |                           |  |  |
| Mobile content volume  |      |                           |  |  |
| Developer  |      |                           |  |  |
| Design   |      |                           |  |  |
| Ease of use  |      |                           |  |  |
| Quality  |      |                           |  |  |
| Contact with the doctor, pharmacist  |      |                           |  |  |
| Control of physiological parameters: blood pressure, weight, glucose, etc. |      |                           |  |  |
| Additional reminders: buying a medicine, visiting a doctor, etc.           |      |                           |  |  |

**19. Are you satisfied with the mHealth app?**

- ☐ completely satisfied
- ☐ rather satisfied
- ☐ difficult to answer
- ☐ rather unsatisfied
- ☐ completely unsatisfied

**20. Will you use mHealth apps in the future to control medication intake?**

- ☐ definitely yes
- ☐ rather yes
- ☐ difficult to answer
- ☐ rather no
- ☐ definitely no

## APPENDIX 2. INFORMATION FOR THE SURVEY PARTICIPANT

**Dear survey participant!**

**Research title:** MARKETING EVALUATION OF CONSUMER PREFERENCES IN USING MOBILE APPS FOR HEALTHCARE TO SUPPORT DRUG ADHERENCE

**The research is aimed at** studying and analyzing consumer preferences in using mobile healthcare applications (mHealth) to support and promote patients' adherence to drugs in Russia.

**Research objectives:** to establish the degree of patients' drug adherence in Russia and ways to support it; to show the main barriers to the introduction of mHealth apps for drug intake control; to identify the factors that shape consumer preferences in using mobile apps; to conduct positioning of consumer preferences in using mHealth apps popular in Russia.

**The research duration:** the field phase lasts for 4 months: March-June 2019.

**Sample size:** 1,100 people. The sample size is stipulated by time and resource constraints.

**Research methods:** personal oral survey and web-based survey using a structured questionnaire.

**Survey participation:** anonymous, voluntary.

**Characteristics of survey participants**

All respondents are divided into two target segments.

Target segment 1 (550 people) - pharmaceutical workers and students with major in Pharmacy.

Target segment 2 (550 people) - mHealth apps consumers, or members of the general public.

**Possible benefits for respondents from participating in the survey.** Survey participants can obtain additional information on the possible benefits of supporting drug adherence, on existing methods for controlling drug intake, on modern mobile healthcare apps and their characteristics, which will contribute to the effective treatment and prevention of chronic diseases.

**Possible risks associated with the survey.** The risks associated with the confidentiality of the information obtained during the survey can be mitigated by assigning a code to each profile, which will be securely stored.

**Inconvenience and additional burdens when participating in the survey.** The survey may take 20-30 minutes. Issues of ranking factors and their evaluation can present certain difficulties requiring additional clarification and assistance.

**Responsibilities of the survey participant in the course of the survey:** participation in the full volume of the survey, sincere and honest answers.

**Information on the confidentiality of survey participants' data.** Interviewers participating in the survey will be further warned of the obligation to keep the information about respondents confidential. A market researcher is required to monitor the confidentiality of information about the participants in the survey.

# CONTROLE DE ODORES EM PRODUTOS ALIMENTARES USANDO FIBRAS ALIMENTARES

## ODOR CONTROL IN FOODS USING DIETARY FIBERS

### РЕГУЛИРОВАНИЕ ЗАПАХА В ПИЩЕВЫХ ПРОДУКТАХ ИСПОЛЬЗОВАНИЕМ ПИЩЕВЫХ ВОЛОКОН

## RESUMO

O objetivo do presente trabalho é determinar a capacidade do farelo de trigo de eliminar o cheiro desagradável de peixe através da conversão de substâncias voláteis em não voláteis, bem como o efeito do farelo de trigo no valor nutricional de amostras tratadas termicamente de tecido muscular picado de peixe. Os principais métodos de pesquisa incluem o método Kjeldahl, para determinar o conteúdo de extratos nitrogenados, a cromatografia gás-líquido para determinar a composição de ácidos graxos e o organismo de teste de ciliado de *Tetrahymena pyriformis* para determinar o valor biológico relativo. Como resultado, a capacidade das fibras alimentares de eliminar um cheiro desagradável de peixe pela conversão de extrativos nitrogenados voláteis em não voláteis foi demonstrada pelo exemplo do farelo de trigo: uma série de experimentos realizada para identificar a dependência do conteúdo de óxido de trimetilamina e nitrogênio de bases voláteis em amostras de tecido muscular picado da navaga, dependendo da proporção de farelo de trigo adicionado, verificou-se que em todas as amostras há uma diminuição no conteúdo de extrativos com um aumento na fração de massa de farelo de trigo. Além disso, o farelo não moído contribui mais ativamente para o processo de neutralização do odor. Foram identificadas a composição dos ácidos graxos dos lipídios da navaga do Extremo Oriente *Eleginus gracilis*, farelo de trigo e sua mistura, e o efeito no valor biológico relativo determinado no organismo de teste de amostras experimentais após tratamento térmico (escaldamento e fervura).

**Palavras-chave:** farelo de trigo, extrativos nitrogenados, composição de lipídios dos ácidos graxos, valor biológico relativo.

## ABSTRACT

The aim of the present work is to determine the ability of wheat bran to eliminate an unpleasant fish smell by converting volatile extractive substances to nonvolatile ones, as well as the effect of wheat bran on the nutritional value of thermally treated samples of minced muscle tissue of fish. The main methods for research include the Kjeldahl's method for determining the content of nitrogenous extractives, the gas-liquid chromatography for determining the composition of fatty acids, and the test organism of *Tetrahymena pyriformis* ciliate for determining the relative biological value. As a result, the ability of dietary fibers to eliminate an unpleasant fish smell by converting volatile nitrogenous extractives into nonvolatile ones has been shown by the example of wheat bran: in a series of experiments to identify the dependence of the content of trimethylamine oxide and nitrogen of volatile bases in samples of minced muscle tissue of the navaga, depending on the proportion of added wheat bran, it has been found that in all samples there is a decrease in the content of extractives with an increase in the mass fraction of wheat bran. Moreover, unmilled bran more actively contributes to the process of neutralizing odor. The fatty acid composition of the lipids of the Far Eastern navaga *Eleginus gracilis*, wheat bran and their mixture, and the effect on the relative biological value determined on the test organism of experimental samples after thermal treatment (scalding and boiling) have been identified.

**Keywords:** wheat bran, nitrogenous extractives, fatty acid composition of lipids, relative biological value.

## АННОТАЦИЯ

Целью работы являлось определение способности пшеничных отрубей устранять неприятный рыбный запах путем перевода летучих экстрактивных веществ в нелетучие, а также влияние пшеничных отрубей на пищевую ценность термически обработанных образцов из измельченной мышечной ткани рыбы. В качестве основных методов для проведения исследований были выбраны: рекомендации Кельдаля для определения содержания экстрактивных азотистых веществ, газожидкостная хроматография для определения состава жирных кислот, тест-организм инфузория *Tetrahymena pyriformis* для определения относительной биологической ценности. В результате была показана способность пищевых волокон на примере пшеничных отрубей устранять неприятный рыбный запах путем перевода азотистых летучих экстрактивных веществ в нелетучие: в серии экспериментов по выявлению зависимости содержания триметиламинооксида и азота летучих оснований в образцах из измельченной мышечной ткани наваги, в зависимости от доли добавляемых пшеничных отрубей, было установлено, что во всех образцах наблюдается снижение содержания экстрактивных веществ с увеличением массовой доли пшеничных отрубей. Причем неизмельченные отруби более активно способствуют процессу нейтрализации запаха. Определен жирнокислотный состав липидов дальневосточной наваги *Eleginus gracilis*, пшеничных отрубей и их смеси, и влияние на относительную биологическую ценность, определенную на тест-организме, экспериментальных образцов после термической обработки (бланширование и варка).

**Ключевые слова:** пшеничные отруби, азотистые экстрактивные вещества, жирнокислотный состав липидов, относительная биологическая ценность.

## 1. INTRODUCTION

The development of the technology of products from minced fish is promoted by the wide possibilities of carrying out various modifications on its basis with the aim of regulating nutritional value and creating enriched and functional food products. The traditional raw materials for minced meat production are fish with predominantly light muscle tissue, low-fat content, and high content of myofibrillar proteins (Hagen and Johnsen, 2016; Murthy *et al.*, 2017; Gonçalves and Salas-Mellado, 2018; Cardoso *et al.*, 2019; Chen *et al.*, 2020; Gu *et al.*, 2020).

The authors had carried out the studies which allowed establishing that when using two indicators: the conditional protein coefficient ( $C_p$  – the ratio of nitrogen of the protein salt-soluble fraction to nitrogen of the water-soluble fraction) and the structure formation coefficient ( $C_{st}$  – the ratio of the nitrogen content of the salt-soluble fraction to total nitrogen), it was possible to qualify how much fish was suitable for minced meat production (Bidenko and Rambesa, 1978). With  $C_p < 1$  and  $C_{st} < 0.2$ , poorly formed minced meat with rigid consistency (e.g., pollock, blue whiting, cardinalfish) is obtained. At  $C_p 1 - 1.2$  and  $C_{st} \sim 0.2$ , the formability of minced meat increases (e.g., Baltic cod, Macrourus icefish). The best raw material for obtaining well-formed minced meat with a high ability to hold water is fish with  $C_p > 1.2$  and  $C_{st} > 0.2$ . These species include herring, ivasi,

horse mackerel, and scomber mackerel. These are just those types of objects that contain a significant amount of dark muscle tissue. Unlike light muscles, dark ones consist of thin dark fibers, the space between which is filled with sarcoplasm with a high content of glycogen, myoglobin, cytochrome C, i.e., substances that accelerate the oxidation of lipids (Kolakovskii, 1991; Lee, Seki, and Kato, 1990; Obatake, 1985). The total lipid content in dark muscles is 5 to 20 times greater than in light ones.

All this, including high iron content (up to 75 %), which is not part of the myoglobin heme, and increased enzymatic activity contribute to the susceptibility of dark muscles to rapid oxidation, and to the formation and rapid growth of an unpleasant odor. Moreover, the deeper the degree of dressing of raw materials is, the longer the contact with atmospheric oxygen is, and the more intense the oxidation processes are (Boitsova, Doroshenko, and Shipova, 2001).

At the same time, certain fish species with predominantly light muscles, low-fat content, low enzymatic activity, and practically not subject to oxidation, are also not suitable for the production of good quality minced meat. Thus, a typical representative of codfishes, pollock (*Theragra chalcogramma*), is characterized by a high content of trimethylamine oxide in the light muscles (TMAO up to 10.80 mg/g). Immediately after catching, the TMAO breaks down into trimethylamine (TMA) and formaldehyde in muscle

tissue of pollock, which have a significant effect on the specific taste and aromatic properties of minced meat (Crapo and Himelbloom, 1994; Greene and Bernatt-Byrne, 1990).

These specific features of pollock are among the reasons for the undesirable use of pollock for obtaining unwashed minced meat, and it is used only for the production of surimi.

Surimi technology involves mincing fish muscle tissue and washing it with water to remove water-soluble components: sarcoplasmic (water-soluble) proteins, enzymes, nitrogenous extractives, including TMAO, TMA, and formaldehyde. Surimi practically consists only of myofibrillar (salt-soluble) proteins, has no negative smell and taste. Surimi is the main raw material for the production of structured analog products. However, its output is only from 12 to 15 % by weight of the whole fish (Li and Chen, 2009; Filomena-Ambrosio *et al.*, 2016; Iwashita *et al.*, 2016; Li *et al.*, 2016; Konno, 2017; Houjyo *et al.*, 2017; Sipailiene, 2017; Zhang *et al.*, 2017; Ma *et al.*, 2017; Jin *et al.*, 2018; Gao *et al.*, 2018).

It is known that dietary wheat fiber, wheat bran (WB), has a sorption ability, including in relation to a number of metals (Guillon and Champ, 2000; Lin *et al.*, 2019; Zhang, Huang and Ou, 2011).

It has been suggested that substances adding an unpleasant smell to minced fish products can also be absorbed by dietary fiber. In addition, there are a number of works devoted to the introduction of dietary fiber into the composition of minced meat of surimi from other fish species: Alaska pollock (Alakhrash, Anyanwu, and Tahergorabi, 2016; Debusca, Tahergorabi, Beamer, Matak, and Jaczynski, 2014), silver carp (Yin *et al.*, 2019), bighead carp (Alipour, Rezaei, Shabanpour, and Tabarsa, 2018, 2019).

The purpose of these studies is to determine the ability of WB to eliminate an unpleasant fish smell by converting volatile extractive substances to nonvolatile ones, as well as the effect of WB on the nutritional value of thermally treated samples of minced muscle tissue of fish.

## 2. MATERIALS AND METHODS

For the model system, minced meat of the muscle tissue of the Far Eastern navaga (*Eleginus gracilis*) as an object containing light and dark muscles, up to 0.002 mg/g of formaldehyde, and 0.5 – 1.4 % of lipids, was selected. These

components, in addition to the formation of an unpleasant odor, contribute to a decrease in the water-holding ability of the protein due to the binding of amine groups and the formation of methylene-amine complexes.

WB was used as a sorbing complex, part of which had been preliminarily milled to sizes less than 250 microns, and the other part had been left to industrial production. The main part size was from 350 to 600 microns.

The content of nitrogenous extractives was determined by Kjeldahl's method (Regenstein and Regenstein, 1984). It was based on the organic matter oxidation during combustion in sulfuric acid in the presence of a catalyst, the distillation of ammonia formed by steam, trapping it with a solution of sulfuric acid and determination of the nitrogenous substances content by titration.

To determine the composition of lipid fatty acids, hydrolysis of lipids isolated by the Bligh-Dyer method (Bligh and Dyer, 1959) and methylation of higher fatty acids by the method of Metcalf and Schmitz (Metcalf and Schmitz, 1961) were performed. The obtained fatty acid methyl esters were analyzed by gas chromatography on a G-180 Yanako device (Japan) and a Shimadzu gas-liquid chromatograph using Argon gas. Identification was carried out according to the methods of Miwa (1963); Cfrreau and Dubacq (1978).

To determine the relative biological value, the test organism of the *Tetrahymena pyriformis* ciliate was used. The ciliate has small body sizes: 20 by 50 microns, the weight of one tetrahymena is  $1.8 \cdot 10^{-9}$  g. It gives 7.51 divisions per day, which is directly dependent on such vital factors as growth and stimulation of vital processes. The ciliate is cultivated on a protein nutrient medium, and the optimal cultivation temperature is 25 °C. For the analysis, 0.02 ml of a three-day culture and 1 – 3 g of the test product were used. The duration of the analysis was four days.

The relative biological value and biological activity of the ciliate were compared with the whole milk. The essence of the method for determining biological activity is to establish the moment of the growth stationary phase of the ciliate at the limiting level of samples of the studied and standard samples and to determine the rate of reproduction in the studied sample in comparison with the standard one. Exact quantitative accounting of the grown individuals was carried out in the Gorjaev's count chambers. The samples that had not shown death or other pathological changes in tetrahymena within four days were left for further

incubation for up to seven days to identify the possibility of long-term negative consequences (Ignatiev and Myagkov, 1980; Mohr, 1981; Shulgin, Shulgina, and Petrov, 2006, pp. 83-95).

The reliability of the obtained experimental data was ensured by the method of mathematical statistics. Reliability is 0.90 – 0.95 (P), and the confidence interval is  $\pm 5$  %.

### 3. RESULTS AND DISCUSSION

In a series of experiments to identify the dependence of the content of TMAO and volatile base nitrogen (VBN) in samples of minced muscle tissue of navaga, depending on the proportion of added WB, it was found that there was a decrease in the content of extractive substances with an increase in the mass fraction of WB in all samples (Figure 1, Figure 2). Moreover, unmilled bran more actively contributes to the process of neutralizing odor than milled one up to a size of 250 microns, despite the large sorption surface. Obviously, this is due to the violation in the milling process of not only physical dimensions but also the chemical structure of bran, which affects their ability to sorb volatile bases and TMA.

Wheat bran also has a positive effect on the fatty acid composition of the minced meat. The nutritional value of fish lipids is characterized by the presence of higher polyunsaturated fatty acids, which are necessary for normal human life. There are about 49 % of them in the navaga lipids (Table 1). Moreover, such types of thermal treatment as boiling in water and scalding practically do not influence the reduction of their quantity. The recorded fluctuations are within the error limits. WBs themselves also contain polyenoic acids, especially a large amount of linoleic acid (18:2 $\omega$ 6 – up to 51.88 %), which is characteristic of plant raw materials.

The addition of 5 % of WB to the minced muscle tissue of navaga leads to an increase of four times in the mass fraction of linoleic acid, and of linolenic acid (18:3 $\omega$ 3) – 1.5 times. The content of other polyunsaturated fatty acids (arachidonic 20:5 $\omega$ 3, eicosapentaenoic 22:5 $\omega$ 3, and docosahexaenoic 22:6 $\omega$ 3) is practically unchanged and does not depend on the thermal treatment method.

The presence of WB practically does not affect the content of saturated fatty acids. Their total amount decreases somewhat when scalding and, to a greater extent, when cooking in water, apparently due to the transition of the fat fraction into the broth.

Among monoenoic fatty acids, the oleic one (18:1 $\omega$ 9) and its isomer (18:1 $\omega$ 7) are the most characteristic of fish. Their ratio should be 2:1, and this ratio, despite natural minor losses during thermal treatment, remains unchanged.

Considering that the properties of odor are determined by organoleptic sensations, experimental samples of minced muscle tissue of navaga with the addition of 5 % of WB have been prepared. Products of 6x3x3 size were formed from the mixture and were thermally treated. Other components of the formulation were not involved in the experiment.

The results of the organoleptic evaluation confirmed the data of the chemical tests. Tasters noted a pleasant smell with a bread aroma and a meat-like taste.

The relative biological value of the experimental samples in comparison with the standard one (whole cow's milk), determined on the test organism, shows a slightly lower result (Table 2). However, the addition of WB only slightly reduces the relative biological value compared with the muscle tissue of fish without WB (by 2 – 6 %). At the same time, the thermal treatment of the experimental samples (scalding, frying) promotes more active cell growth.

### 4. CONCLUSION:

It has been found that wheat bran sorbs volatile extractive nitrogenous compounds (TMAO and VBN), contributing to the neutralization of fish smell. In this case, additional milling of WB is not required. Moreover, the addition of WB leads to an increase in the mass fraction of essential linoleic and linolenic fatty acids, which is characteristic of plant raw materials. In this case, the content of other polyunsaturated fatty acids is practically unchanged and does not depend on the thermal treatment method. The obtained results and the established VBN suggest that ready-made foods made from minced muscle tissue of fish with the addition of WB will have high nutritional value.

## RESUMO

A resistência antimicrobiana tornou-se uma grande preocupação em todo o mundo. No presente trabalho, foi realizada a triagem fitoquímica do extrato etanólico e das frações de flores de *Tecoma stans* e avaliou-se o potencial antimicrobiano, através do ensaio de microdiluição em caldo sobre 10 isolados de interesse clínico. Também foi avaliada a interação das combinações de amostras de *T. stans* com antimicrobianos comerciais. As amostras de *T. stans* demonstraram atividade antibacteriana e potencial fungistático sobre *Proteus mirabilis*, *Proteus vulgaris*, *Staphylococcus aureus*, *Streptococcus mutans* e *Candida infanticola*, especialmente o extrato etanólico e as frações diclorometânica e acetatoetílica, com valores de Concentração Inibitória Mínima (CIM 2000 - 500 µg/mL). A combinação das amostras de *T. stans* com os antimicrobianos mostrou efeitos sinérgicos e aditivos. Nas combinações classificadas como interação sinérgica, observou-se que a CIM para o antimicrobiano, em combinação com as amostras de *T. stans*, foi reduzida de 2 a 7 vezes em comparação com a CIM para o antimicrobiano, quando utilizado isoladamente. Os melhores resultados foram encontrados para a combinação do extrato etanólico com amoxicilina sobre *P. mirabilis* e do extrato etanólico e da fração diclorometânica com tetraciclina sobre *S. aureus*. Testes de combinações do extrato e das frações de *T. stans* com antimicrobianos são inéditos, tornando esses resultados promissores. Na caracterização fitoquímica foi possível observar a presença de alguns compostos fenólicos, o que pode justificar o potencial antimicrobiano de *T. stans*. Destaca-se a importância de identificar novos agentes antimicrobianos, alguns dos quais podem estar presentes na flora inexplorada do Brasil.

**Palavras-chave:** Antimicrobiano, Extrato, Fitoquímica, Sinergismo.

## ABSTRACT

Antimicrobial resistance has become a significant concern worldwide. In the present work was performed the phytochemical screening of ethanol extract and fractions of *Tecoma stans* flowers, and evaluated the antimicrobial potential by a broth microdilution assay against 10 isolates of clinical interest. Also was assessed the interaction of combinations of *T. stans* samples with commercial antimicrobials. The samples of *T. stans* demonstrated antibacterial activity and fungistatic potential against *Proteus mirabilis*, *Proteus vulgaris*, *Staphylococcus aureus*, *Streptococcus mutans*, and *Candida infanticola*, especially the ethanol extract and the dichloromethane and ethyl acetate fractions, with Minimal Inhibitory Concentration values (MIC 2000 - 500 µg/mL). The combination of *T. stans* samples with antimicrobials showed synergistic and additive effects. In combinations classified as synergistic interaction, was observed that MIC for the antimicrobial in combination with the samples of *T. stans* was reduced by 2 to 7 times compared to the MIC for the antimicrobial when used alone. The best results were found for the combination of the ethanol extract with amoxicillin against *P.*

*mirabilis*, and the ethanol extract and the dichloromethane fraction with tetracycline against *S. aureus*. Tests of combinations of extract and fractions of *T. stans* with antimicrobials are unprecedented, making these results promising. In the phytochemical characterization, it was possible to observe the presence of some phenolic compounds, which may justify the antimicrobial potential of *T. stans*. It is important to highlight the identification of new antimicrobial agents, some of which may be present in the unexplored flora of Brazil.

**Keywords:** Antimicrobial, Extract, Phytochemistry, Synergism.

## 1. INTRODUCTION

The increasing resistance of fungi and bacteria to traditionally used antimicrobials represents one of the major concerns faced by humanity in recent times, associated with severe consequences such as an increase in microbial infections (Costa and Junior, 2017; Nikaido, 2009). Therefore, the production of drugs from natural products has been encouraged in several countries (Aumeeruddy-Elalfi *et al.*, 2015).

Higher plants may represent a promising alternative as they are capable of synthesizing compounds with antimicrobial activity, and these substances can be used against the development of infections in humans. In this sense, is highlight the phenolic compounds that are commonly associated with the antibacterial and antifungal activity of plants (Carvalho *et al.*, 2018; Lima *et al.*, 2016; Orhan *et al.*, 2010). Also, plant extracts can be combined with commercial antibiotics and present some interactions. These combinations can expand the spectrum of activity of antimicrobials, increasing their effectiveness in the treatment of infections, and reducing the minimum inhibitory concentration against resistant pathogens (Berg and Lubert, 2008; Casanova and Costa, 2017).

*Tecoma stans* (L.) ex Kunth is an exotic species found in Brazil, which is commonly used in ornamentation. In other countries, such as Mexico, this species is also used in traditional medicine to treat fungal infections and digestive problems (Singh *et al.*, 2013). However, only a few studies have reported its medicinal potential. Thus, this work evaluated the antimicrobial properties of *T. stans* flowers to confirm the medicinal potential of this species in Brazil.

## 2. MATERIALS AND METHODS

### 2.1. Plant material and extraction

The flowers of *T. stans* were collected in the Divinópolis municipality of MG state (coordinates 20°10'44"S, 44°55'6"W) in April

2018, according to the registration of botanical material collection performed at the SISBIO (no. 30006 in 20/03/2018). A voucher specimen was deposited in the institution herbarium Pesquisa e Agropecuária de Minas Gerais (EPAMIG/PAMG) and identified as *Tecoma stans* (L.) Juss. ex Kunth (PAMG 58384).

The flowers were dried in an oven at 40 °C for 7 days, crushed in a mechanical mill, and extracted with ethanol 70% in a proportion of 9:1 (ethanol/plant) by turbo extraction (Ultra-Turrax, MA-102 Plus). The solvent was removed in a rotary evaporator (IKA-HB10) to obtain the ethanol extract (EE, 37.49 g). Subsequently, 10 g of the obtained EE was solubilized in 100 mL of ethanol/water (7:3), and fractionated by a liquid-liquid partition, obtaining hexane (HEX, 0.62 g), dichloromethane (DCM, 1.19 g), ethyl acetate (AC, 5.41 g), and hydroethanol residue (HE, 2.08 g) fractions (Gonçalves, 2020).

### 2.2. Phytochemical analysis

The EE and fractions were submitted to phytochemical screening to evaluate the presence of the main classes of secondary metabolites for the identification of flavonoids, coumarins, saponin alkaloids, tannins, steroids, and triterpenoids (Matos, 2009; Silva *et al.*, 2010), characterized by chemical reactions that result in the development of staining, precipitation, and foams.

- A) Tannins: this test was performed by adding of FeCl<sub>3</sub> alcoholic solution 5% w/v (5 g/100 mL) with the formation of precipitate or not, being blue precipitate indicative of hydrolyzable tannins, and green precipitate indicative of condensed tannins (Matos, 2009; Silva *et al.*, 2010).
- B) Triterpenoids and steroids: this test was performed by the Liebermann-Buchard reaction (H<sub>2</sub>SO<sub>4</sub> + acetic anhydride). The upper phase of blue or green color indicated the presence of steroids, and red, pink, purple, or violet interphasic halo indicated the presence of triterpenes (Matos, 2009; Silva *et al.*, 2010).

- C) Saponins: the sample was shaken vigorously with distilled water for 1 minute, and the presence of persistent foam for 15 minutes indicated the presence of saponins (Matos, 2009; Silva *et al.*, 2010).
- D) Coumarins and anthraquinones: this test was performed by adding NaOH solution 1 M. The yellow color indicated the presence of coumarins, and violet to the purple color indicated the presence of anthraquinones (Silva *et al.*, 2010).
- E) Alkaloids: this test was performed by adding Drangendorff reagent with the formation of precipitate or not. The formation of insoluble and flocculent precipitate was indicative of the presence of alkaloids (Silva *et al.*, 2010).
- F) Flavonoids: this test was performed by adding of H<sub>2</sub>SO<sub>4</sub> concentrated solution. The yellow, orange or red color was indicative of flavonoids (Silva *et al.*, 2010).

### 2.3. Antimicrobial potential assay

The microorganisms used in this study originated from American Type Culture Collection (ATCC) and were provided by the microorganism reference laboratory of the Fundação Oswaldo Cruz (FIOCRUZ, Rio de Janeiro, Brasil). Eight species were used: *Klebsiella oxytoca* (ATCC 0182), *Proteus mirabilis* (ATCC 15290), *Proteus vulgaris* (ATCC 13315), *Enterobacter cloacae* (ATCC 23355), *Staphylococcus aureus* (ATCC 25923), *Staphylococcus epidermidis* (ATCC 12228), *Streptococcus mutans* (NCTC 10449), *Streptococcus agalactiae* (ATCC 13813). In antifungal tests, *Candida infanticola* (UFSJ6A), and *Candida glabrata* (ATCC 2001) were used.

The bacterial susceptibility test was performed according to the CLSI (Clinical and Laboratory Standards Institute) document guidelines M100-S25 (2015). The bacterial inoculum colonies isolated from a 24-hour growth streak were transferred to tubes containing saline solution 0.85% (p/v). Inoculum was prepared by dilution of a suspension corresponding to 0.5 on the McFarland density scale ( $DO_{530nm} = 0.19 - 0.21$ ) in Mueller-Hinton broth (MH) (1:10) to obtain a final inoculum with  $7.5 \cdot 10^5$  UFC/mL, which was used to assay. The fungal suspension was prepared in a similar way (NCCLS, 2002), to obtain a final inoculum with  $1 \cdot 10^3$  UFC/mL, which was used to assay. Stretch marks of 48 h of growth were used to obtain the suspension in saline, and later adjusted to 0.5 on the McFarland scale ( $DO_{530nm} = 0.19 - 0.21$ ), representing a cell density of approximately  $1 \cdot 10^6$  UFC/mL. To

obtain the final inoculum, two dilutions were performed, produced by transferring 20  $\mu$ L of the suspension to 980  $\mu$ L of Sabouraud dextrose (SD) broth and, subsequently, from 1 mL of the resulting suspension to 19 mL of SD broth. The samples were dissolved in water/DMSO (9:1), obtaining the initial concentration of 40 mg/mL. The MIC was carried out in 96-well polystyrene microplates containing 100  $\mu$ L of the liquid medium, 20  $\mu$ L of the samples solution (ranging from 2000 to 2  $\mu$ g/mL, dissolved in 9:1 water:dimethylsulfoxide), and 100  $\mu$ L of the different microbial inoculum in each well. After microdilution, they were incubated in a bacteriological incubator (Nova Instruments) at 37 °C for 24 h for bacteria, and at 28 °C for 48 h for yeasts, and the minimum inhibitory concentration (MIC) was defined as the lowest concentration of samples without visible growth of microorganisms. Subsequently, the minimal bactericidal concentration (MBC) was defined as the lowest concentration of samples that inhibit bacterial growth, as described by Lyu *et al.* (2016). Amoxicillin, tetracycline, and ketoconazole were used as positive controls. Water/dimethylsulfoxide (DMSO) 9:1 v/v was used as solvent control. The tests were carried out in triplicate wells, with three independent repetitions between them.

### 2.4. Evaluation of combinations

For the evaluation of synergistic, additive, or antagonistic effects between antimicrobials (amoxicillin and tetracycline), and *T. stans* samples that presented a MIC (inhibition between 1000 and 500  $\mu$ g/mL) against the tested microorganisms, the "checkerboard" method was used (Lee *et al.*, 2012; Oroojalian *et al.*, 2010). In the 96-well plates, the antimicrobial was added horizontally, and then *T. stans* samples were added vertically in concentrations of 125 to 0.9  $\mu$ g/mL, combined in a proportion of 1:1, to evaluate whether there is a combined antimicrobial effect. The resulting assay included a total of 64 combinations. After the distribution of the samples, 100  $\mu$ L of MH was added to each well with the bacterial inoculum at  $7.5 \cdot 10^5$  CFU/mL, and the plates were incubated in an oven at 35 °C for 16 to 20 hours. For the positive control, MH broth and microbial inoculum were used; only the MH broth was used for the sterility control, and water/dimethylsulfoxide (9:1) was used as the solvent control. As standards, amoxicillin and tetracycline antimicrobials were used. The MIC was determined for antimicrobials

and *T. stans* samples alone and in different combinations. After visual reading from those wells that had no microbial growth detected with the naked eye, the calculation of the fractional inhibitory concentration (FIC) of each compound was determined by Equations 1 to 3.

$$\text{FIC (antimicrobial)} = \text{MIC (antimicrobial) in combination} / \text{MIC (antimicrobial) alone} \quad (\text{Eq. 1})$$

$$\text{FIC (extract)} = \text{MIC (sample) in combination} / \text{MIC (sample) alone} \quad (\text{Eq. 2})$$

$$\text{FIC index (FICI)} = \text{FIC antimicrobial} + \text{FIC sample} \quad (\text{Eq. 3})$$

The combinations were considered synergic when  $\text{FICI} \leq 0.5$ , additive or indifferent at  $0.5 < \text{FICI} \leq 2.0$ , and antagonistic when  $\text{FICI} > 2.0$  (He and Chen, 2006; Oroojalian *et al.*, 2010; Palaniappan and Holley, 2010).

### 3. RESULTS AND DISCUSSION

The results of the phytochemical screening are presented in Table 1. In the EE, flavonoids, alkaloids, coumarins, saponins, and condensed tannins were observed. The HEX fraction contained alkaloids and steroids. The DCM, AC, and HE fractions were similar and contained alkaloids, saponins, and coumarins. In the DCM fraction, flavonoids were also observed, and the AC fraction also contained flavonoids, and condensed tannins. A previous study by Raju *et al.* (2011) confirmed the presence of flavonoids, saponins, tannins, and glycosides in the floral extracts of *T. stans*. Salvadó *et al.* (2002) showed the presence of triterpens, steroids, phenols, taninns, alkaloids, and flavonoids in dry and fresh leaves of *T. stans*.

The extract and fractions showed antimicrobial activity against *P. mirabilis*, *P. vulgaris*, *S. aureus*, *S. mutans*, and *C. infanticola*, except the HE fraction. The best results obtained in this study were for the EE, DCM, and AC fractions (Table 2). The EE and AC fraction exhibited an effect against *P. mirabilis*, and the AC fraction against *S. aureus* (MIC of 500 µg/mL and MBC of 1000 µg/mL). Some flavonoids have the ability to form antimicrobial barriers as a

response by plants to microbial infection. Thus, there has been an increase in the number of studies on flavonoids as potential antimicrobial agents (Gutiérrez-Venegas *et al.*, 2019). The presence of flavonoids in *T. stans* flowers may explain its antibacterial potential. Gutiérrez-Venegas *et al.* (2019) previously demonstrated antibacterial activity of the flavonoid apigenin against strains of *Escherichia coli*, *Enterococcus faecalis*, and *S. aureus* present in dental plaque.

The *T. stans* extract, and fractions that showed the most effective action in the MIC/MBC tests were submitted to the checkboard method to verify whether there were any interactions of these samples when combined with the commercial antimicrobials amoxicillin and tetracycline (Table 3). The samples showed synergistic and additive interactions when combined with commercial antimicrobials. In combinations classified as a synergistic interaction, we observed that the MIC for the antimicrobial in combination with *T. stans* samples was reduced by 2 to 7 times in comparison with the MIC of the antimicrobial when used alone. The best results were found for the combination of EE with amoxicillin against *P. mirabilis*, and EE and DCM fraction with tetracycline against *S. aureus*.

The association of plant extracts and antimicrobials has been observed previously. Araújo *et al.* (2014) reported the synergic potential of ethanol extracts from Lamiaceae species (*Melissa officinalis*, *Mentha* sp., *Ocimum basilicum*, *Plectranthus barbatus*, and *Rosmarinus officinalis*) with streptomycin against *E. faecalis*, *S. aureus*, *S. mutans*, *E. coli*, and *Pseudomonas aeruginosa*. The association of antimicrobials with medicinal plants or their derivatives in the treatment of microbial infections can increase the bioavailability of active substances, decrease toxicity and adverse effects, decrease resistance and increase therapeutic efficacy, allowing the use of these drugs when their effectiveness as a single agent in the treatment of infections is reduced (Chung *et al.*, 2011; Van Vuuren and Viljoen, 2011).

### 4. CONCLUSIONS

In conclusion, these results regarding the antimicrobial effect of *T. stans* flowers corroborate the data already presented in the literature, and this study is the first to report these effects in plants of this species from Brazil. The samples obtained from the flowers of *T. stans*

exhibited antimicrobial action against *P. mirabilis*, *P. vulgaris*, *S. aureus*, *S. mutans*, and *C. infanticola*, and that effect can be explained by the presence of phenolic compounds in these samples. The combination of plant samples with antimicrobials demonstrated an important interaction, potentiating the antimicrobial effects. The best results were observed for the combination of EE with amoxicillin against *P. mirabilis*, and EE and DCM fraction with tetracycline against *S. aureus*.

**RESUMO**

A eficácia da criação de gado é amplamente determinada por uma base sólida de alimentação. Atualmente, a produtividade do gado na Federação Russa está aumentando e isso requer uma abordagem mais cuidadosa para avaliar a qualidade da alimentação. Isso, em primeiro lugar, diz respeito a tipos de alimentos como feno, silagem, haylage, que representam 60-85% da dieta diária média dos animais. O valor nutricional desses tipos de alimentos depende em grande parte do conteúdo e da proporção de proteína bruta e fibra bruta nas ervas perenes quando são colhidas. Nos estágios iniciais do desenvolvimento da planta, a proteína bruta predomina em sua composição e o teor de fibras é insuficiente. Portanto, cortar ervas perenes nesse período é irracionalmente. Com o crescimento e desenvolvimento da planta, sua transição para o estágio da emergência da espiga, o teor de proteína bruta diminui com o aumento do teor de fibras. A colheita de ervas perenes durante o período em que contêm uma grande quantidade de fibras e baixa proteína também é irracional, uma vez que o baixo teor de proteína nos alimentos não contribui para o crescimento da produtividade animal. O momento ideal para a colheita das ervas é considerado o momento em que o teor de proteína bruta é de 14 a 16% e da fibra bruta – 26 a 28%. Determinar o conteúdo desses elementos é um processo bastante trabalhoso e caro, a análise dura cerca de 3 dias. Somente grandes empresas agrícolas podem se dar ao luxo de realizar essas análises. Ao mesmo tempo, hoje existem tecnologias para exame remoto de culturas, que neste caso podem ser realizadas usando veículos aéreos não tripulados (VANTs). Atualmente, com a ajuda deles, determina-se o teor de nitrogênio nas plantas. Os autores deste artigo propõem uma técnica digital para determinação remota de fibra bruta e proteína bruta, que determina o momento ideal da preparação de alimentos.

**Palavras-chave:** *composição dos alimentos, análise remota, composição química das plantas, veículos aéreos não tripulados, sensores infravermelhos de nitrogênio.*

## ABSTRACT

The effectiveness of cattle breeding is mostly determined Forage base. Currently, cattle productivity in the Russian Federation is increasing, and this requires a more careful approach to assessing the quality of feed. This primarily applies to such types of feed like hay, silage, haylage, which make up 60-85% in the average daily diet of livestock. The nutritional value of these types of feed depends mostly on the content and ratio of crude protein and crude fiber in perennial grasses when they are harvested. In the early phases of plant development, crude protein predominates in its composition, and the fiber content is insufficient. Therefore, mowing perennial grasses in these terms is irrational. With the growth and development of the plant, its transition to the heading stage, the crude protein content decreases with increasing fiber content. Harvesting perennial grasses at a time when they contain a large amount of fiber and low protein is also irrational since the low protein content in feed does not contribute to the growth of animal productivity. The optimum time for harvesting herbs is considered to be the time when the crude protein content is 14-16%, and crude fiber – 26-28%. Determination the content of these elements is a rather laborious and expensive process, the analysis lasts about three days. Only large agricultural enterprises can afford to carry out such analyses. At the same time, today, there are technologies for remote sensing of crops, which in this case can be carried out using unmanned aerial vehicles (UAVs). Currently, with their help, the nitrogen content in plants is determined. The authors of this paper propose a digital technique for remote determination of crude fiber and crude protein, which determines the optimal timing of the harvesting herbs.

**Keywords:** *feed composition, remote analysis, chemical composition of plants, unmanned aerial vehicles, infrared nitrogen sensors.*

## АННОТАЦИЯ

Эффективность скотоводства во многом определяется прочной кормовой базой. В настоящее время продуктивность крупного рогатого скота в Российской Федерации возрастает и это требует более внимательного подхода к оценке качества кормов. Это, прежде всего, касается таких видов кормов, как сено, силос, сенаж, которые составляют в среднесуточном рационе скота 60-85%. Питательность этих видов кормов во многом зависит от содержания и соотношения сырого протеина и сырой клетчатки в многолетних травах при их заготовке. На ранних фазах развития растения в его составе преобладает сырой протеин, а содержание клетчатки недостаточно. Поэтому скашивание многолетних трав в эти сроки нерационально. С ростом и развитием растения, переходом его в фазу колошения содержание сырого протеина уменьшается при увеличении содержания клетчатки. Заготовка многолетних трав в период, когда в них содержится большое количество клетчатки и мало протеина – также нерациональна, так как низкое содержание протеина в кормах не способствует росту продуктивности животных. Оптимальными сроками заготовки трав считаются те сроки, когда содержание сырого протеина составляет 14-16%, а сырой клетчатки – 26-28%. Определение содержания данных элементов – довольно трудоемкий и дорогостоящий процесс, анализ длится около 3 дней. Только крупные сельскохозяйственные предприятия могут позволить себе производить такие анализы. В то же время сегодня существуют технологии дистанционного зондирования посевов, которые могут в данном случае осуществляться при помощи беспилотных летательных аппаратов (БПЛА). В настоящее время с их помощью определяется содержание азота в растениях. Авторы данной статьи предлагают цифровую методику дистанционного определения содержания сырой клетчатки и сырого протеина, что определяет оптимальные сроки заготовки корма.

**Ключевые слова:** *состав кормов, дистанционный анализ, химический состав растений, беспилотные летательные аппараты, инфракрасные датчики азота.*

## 1. INTRODUCTION

At the present moment, the meat and dairy cattle breeding industry in the Russian Federation continues to reduce production volumes. Among the main reasons are the long production cycle in these sub-sectors and the need to develop a related industry such as feed production with significant sown areas of fodder crops and fodder

land, a long train of equipment, which determines a significant investment and a low rate of return on investment (Khudyakova *et al.*, 2018). This reduces the food security of the Russian Federation in milk and dairy products, as well as in beef. In this regard, the search for ways to increase the efficiency of animal husbandry is very urgent, one of these ways is to strengthen the feed base – providing livestock with high-quality feed,

increasing feed output while reducing the cost of feed production (Shuai *et al.*, 2019). This can be achieved in many ways due to adherence to feeding production technology. In particular – due to the procurement of feed in optimal terms (Karydas *et al.*, 2020).

In the structure of the feed ration of livestock, a significant part (60-85%) consists of feed produced from perennial grasses – hay, silage, haylage. This paper is devoted to the chemical analysis of the quality of perennial grasses in order to determine the optimal term for their mowing. Large agricultural enterprises, agricultural holdings, which have their laboratories for the analysis of feed, analyse the content of crude protein daily to determine the optimal harvesting time (Schmidhuber and Tubiello, 2007; Misselhorn *et al.*, 2012). This is a time consuming and expensive process. About 1% of agricultural enterprises in the Russian Federation have such laboratories, which is not enough. Moreover, this issue is being resolved in the Russian Federation for significant sown areas of perennial and annual grasses. Currently, the grass area is 18.3% of the cultivated area of the Russian Federation and 90.2% of the cultivated area of fodder crops (Agriculture in Russia, 2019). Despite the determined tendency to reduce the area under forage crops in general, and forage grasses, in particular, they occupy a relatively large area – 14544 thousand hectares (Table 1).

Determining the optimal harvesting time for perennial grasses is an important task. As the herbs grow, the collection of dry matter increases. However, at the same time, their quality may deteriorate in terms of feed value (Kasakova *et al.*, 2019; Tynybekov *et al.*, 2013; Pashtetsky *et al.*, 2018). As a rule, this is expressed in a decrease in the content of crude protein and the accumulation of the fibrous fraction – crude fiber, which leads to a deterioration in the digestibility of the resulting feed and its energy value. In this regard, it is necessary to choose the harvesting dates when the quality would be high enough, at the same time, without compromising yield (Laliberte *et al.*, 2011; Astor *et al.*, 2018).

The nutritional value of perennial herbs is primarily determined by the content of crude protein and fiber. The digestibility of the feed and energy content depends on the fiber content. The productivity of animals directly depends on the amount of protein (Pashtetsky *et al.*, 2018; Pashtetskiy *et al.*, 2020). And therefore, these two criteria should be in the optimal combination to establish the timing of cleaning. It is believed that under production conditions, these parameters

correlate with each other. So, the content of crude fiber in the silage and haylage of the 1st class should not exceed 26-28 in dry matter, with a crude protein level of at least 14-16% (Stepanova, 2019).

## 2. MATERIALS AND METHODS

The main suggestion of the study is to determine protein and fiber in plants by remote sensing of perennial grass crops using unmanned aerial vehicles equipped with special nitrogen sensors. The operation of sensors for non-contact measurement of nitrogen in plant leaves is based on taking into account the degree of light or laser beams reflection from the plant leaf. The more chlorophyll in the leaf, the higher the nitrogen content and the higher the degree of reflection. Sensors can be mounted, for example, on the roof of a tractor or on an UAVs. Such sensors are widely marketed. For example, sensors such as the CropSpec™ Vegetation Level Sensor or the YARA N-Sensor (AgriCon company). And the principle of operation of the N-sensor MiniVeg N system is based on the excitation of chlorophyll by laser beams. This sensor is mounted on the front of the tractor. Sensors can also be portable and displaceable, as for example CCM-200 PLUS sensor (USA). Information technologies such as satellite navigation, unmanned vehicles, and aircraft (UAVs) equipped with all kinds of sensors, IoT-platforms, and Big Data are actively being introduced into agriculture today (Khudyakova *et al.*, 2018). In particular, in solving the problem posed above, technologies for remote sensing of crops can be used. Determination of the critical phase of growth of fodder culture can be carried out using special sensors that are mounted on static installations or UAVs. Together with the analysis of weather data carried out by other sensors mounted on the same devices, they can help determine the optimal harvesting time for forage crops concerning a specific place on the field.

This is the task of precision farming (Karydas *et al.*, 2020; Ismailova *et al.*, 2016; Tarshilova *et al.*, 2016). The International Precision Agriculture Society (ISPA) defined this term as “a management strategy that collects, processes and analyses temporal, spatial and other data, and combines them with other information to support management decisions to improve the use of resources to increase efficiency, productivity, quality, profitability and sustainability of agriculture (International society of precision..., 2019). Precision farming can

significantly increase the efficiency of agricultural production, both due to resource-saving and due to the implementation of a host of measures in optimal terms, which, as in this case, ensures the optimal content of nutrients in the feed and contributes to the growth of livestock productivity by increasing the rate of feed output (Bongiovanni and Lowenberg-DeBoer, 2004; Schmidhuber and Tubiello, 2007; Misselhorn *et al.*, 2012; Lowenberg-DeBoer and Erickson, 2019). The results of multispectral remote sensing from unmanned aerial vehicles and their application in pasture conditions, including low-flying drones, were described in (Laliberte *et al.*, 2011; Astor *et al.*, 2018). Characterisation of plant growth parameters and yield forecasting was done in (Zhou *et al.*, 2017; Shuai *et al.*, 2019; Yudaev *et al.*, 2019).

To solve the problem of non-contact determination of the crude protein content in perennial grasses, we can also use the method of reconnaissance diagnostics of plant conditions using unmanned aerial vehicles (The technique of remote..., 2011). The method involves the formation of a specific reference area of a homogeneous surface next to the field to be tested; the establishment of the boundaries of several control sites in a field with varying degrees of plant density; aerial photography of the field with UAVs with multispectral images. Next, the nitrogen content in plants is measured at control sites using a nitrogen tester, and a spectroradiometer is used to perform ground-based measurements of the spectral brightness of point objects on a reference site and the spectral brightness of a calibration panel. The ground-based spectral brightness coefficients (GSB) are determined by dividing the results of measuring the areas on the reference site with a spectroradiometer by the measurement result of the calibration panel, with the result reduced to the range 0-1 (0-100%). Further, the obtained results are transferred to a computer, where, using special processing, a multispectral orthophoto map of the diagnosed field is formed. Next, atmospheric-corrected GSBs for each pixel of the orthomosaic are calculated by regressing the initial brightness values of the pixels obtained directly during aerial photography to the GSB obtained from ground-based measurements of the reference sites included in the orthomosaic. A normalised difference vegetation index (NDVI) map is constructed, showing the nitrogen content in the plants of the diagnosed field. Calibrate the resulting maps using ground measurement data from reference sites.

To obtain images of crops of perennial grasses to determine the content of nitrogen and digestible protein in plants, UAVs of both airplane, helicopter, and multicopters types can be used. At the same time, the last two species are considered the most acceptable option, since they do not require special take-off space and are able to "hover" over the object. Specialists recommend using the following UAVs for these purposes (Table 2). Today, the market offers several dozen types of UAVs that can be used for the above purposes (Korotaev and Novopashin; 2018 RoboTrends, 2018).

The operation of sensors for non-contact measurement of nitrogen in plant leaves is based on taking into account the degree of light or laser beams reflection from the plant leaf. The more chlorophyll in the leaf, the higher the nitrogen content and the higher the degree of reflection. Such sensors are widely marketed. So, for example, Figure 1 shows the Resonon Pika-L hyperspectral sensor, which has 281 spectral channels (spectral range 400-1000 nm), a lens with a field of view of 17.6 degrees. The camera is mounted on the DJI S1000 octocopter. Sensors can also be mounted on the roof of the tractor (Figure 2).

Compared to static field stations, UAVs have a number of advantages such as high quality of collected data, high quality of image resolution, relatively low price, the ability to select and integrate various sensors. The drones are equipped with various modern technologies such as infrared cameras, GPS, and LASER. UAVs monitor the state of nitrogen to establish the adequacy of its concentration. An analysis of the ripeness of crops and grass using UAVs was carried out in (Honkavaara *et al.*, 2012; Tlesova *et al.*, 2018). The advantages of Spatio-temporal sounding of UAVs in comparison with remote sensing are shown in (Berni *et al.*, 2009; Schwarzbach *et al.*, 2009).

To determine the content of structural carbohydrates, empirical methods are usually used to ensure the separation of carbohydrates according to their digestibility in the process of animal nutrition. So, in the framework of the analysis of feed according to the Weende analysis, the level of structural substances is estimated by the content of crude fiber (CF). However, CF does not represent the sum of indigestible substances, as well as the whole amount of structural carbohydrates (SC), some of which, as well as part of lignin, are removed during its determination and enter, along with non-structural carbohydrates, in the fraction of nitrogen-free extractive substances

(NFE), which includes carbohydrates, significantly different in their digestibility. At the same time, knowledge of the entire amount of SC and its individual components is necessary for a more accurate prediction of feed consumption and digestibility. Neutral-detergent fiber (NDF), representing the total amount of SC and lignin, is one of the most important indicators of feed quality. The feed consumption (Mertens, 2010), its nutritional value (Weiss, 1998), and, ultimately, the productive effect, depending on its level and digestibility. Since the end of the last century, the assessment of feed and rations for the content of detergent forms of fiber in them has become widespread throughout the world. Analysis methods are standardised at the international and interstate levels (GOST ISO 13906-2013, 2013; GOST ISO 16472-2014, 2014). In Russian Federation, some forages and forage grasses were also examined by the level of acid-detergent fiber (ADF) and NDF in the conditions of the Moscow, Kaluga, and Orenburg regions (Vorobyova, 2002; Kharitonov *et al.*, 2008; Levakhin *et al.*, 2015) and Tatarstan (Bykova and Gibadullina, 2010), studies were carried out to study the digestion in bull calves (Levakhin *et al.*, 2007; Bykova and Gibadullina, 2010) and cows (Kharitonov and Khotmirova, 2009) depending on the content of structural carbohydrates in the diet. However, there is still insufficient information on the levels of ADF and NDF in different types of forage grasses, depending on the phase of vegetation and other conditions. Partly in connection with this, forages feed standards (GOST R 55986-2014, 2014) contain standards for CF content, but there are no requirements for levels of detergent forms of fiber.

### 3. RESULTS AND DISCUSSION:

In practical activities, the harvesting time is set based on the phase of growth of plants. For example, for preparing silage, it is recommended to mow grass in the phase of the beginning of the heading, for haylage – in the phase of the end of going booting and the beginning of heading. But the problem is that this or that phase does not occur simultaneously and can last quite a long time – depending on the type of grass. For example, the booting phase lasts up to 20 days. The heading and flowering phase is 7-10 days. During the same phase, the composition of plants changes. The composition of plants can be different in the same phase of development, depending on weather conditions. For example, with a lack of moisture in combination with adverse temperature conditions, even in the phase of the

beginning of booting, the content of crude fiber can reach the level of the earing phase - 30% or more. Therefore, the optimal harvesting time is determined by daily analyses during the harvesting period.

The crude protein content in the feed is related to the nitrogen content. Currently, the nitrogen content in herbs is determined as follows. Herbal samples are taken by a special method. Further, herbs dried at a temperature of 60-65°C in an oven with forced ventilation are grounded until they pass through a sieve with 1 mm openings. A portion of the feed is burned in concentrated sulfuric acid in the presence of a catalyst, and the amount of ammonia formed is determined in one way or another. The ammonia content is determined by the nitrogen content.

Large farms that have reached a high level of animal productivity are forced to conduct such analyses in order to procure high-quality feed daily. But it is quite laborious and expensive. Analysis by conventional chemical methods takes at least three days. Therefore, special studies are carried out in order to develop methods for optimal timing of grass harvesting without analysis. So, sometimes regression equations are used that relate the composition of the plants to their height, the sum of the temperatures, and the amount of rainfall during the growing season of grass. But this requires lengthy research over several years with field trials. The quality of the statistical prediction of the composition is poor.

Precision farming is based on information management and has been made possible thanks to many technological innovations based on information technology. These technologies allow the farmer to receive large amounts of information regarding the state of the soil (moisture content of nutrients in it), the state of crops, and the state of the environment. With this information, management decisions become more appropriate and effective. Information technologies used directly in the field make it possible to isolate from the whole set of factors precisely those whose impact will give the highest results, in particular the yield of forage crops. Ultimately, this increases the profitability of production and its stability (Plant *et al.*, 2000). In particular, remote sensing of crops can be used to determine the crude protein content in feed crops. The ability to determine crude protein (crude protein) in a plant provides a determination of its nitrogen content. It can be determined by multiplying the nitrogen content by 6.25 since the nitrogen concentration in most proteins is, on average, 16%.

Currently, the most common form of remote sensing, including for determining the nitrogen content in plant leaves, is electromagnetic radiation, which is detected by sensors installed on a variety of media - satellites, drones, agricultural machinery, various static installations in the field. Most widely used in agriculture are wavelengths, such as visible light, near-infrared, and thermal infrared. And if thermal infrared radiation is mainly used to remotely determine the stress level of a plant as a result of a lack of nutrients, moisture, etc., then near-infrared radiation can be used to test the content of nutrients in the plant.

Currently, many different sensors have been developed for smart crop production. For example, CLAAS today offers the CROP SENSOR sensor for the biomass and nitrogen index, equipped with a measuring system with four high-power LEDs (How do drones work..., 2019). The measurement frequency of such a sensor is 800 units per second, regardless of the time of day or the nature of the lighting. Such sensors are manufactured by the company for subsequent mounting on equipment traveling in the field, but similar sensors can be installed on low-flying UAVs.

The UAVs listed above and several dozen similar ones using a multispectral camera make it possible to obtain accurate maps of the vegetation index (NDVI), which can serve as the basis for determining the digestible protein content in forage grasses, in increments of up to several centimeters (Figure 3).

An interesting solution was developed by the German company Fritzmeier, which offers agricultural producers the ISARIA plant stand sensor (Sergeev, 2019). Similar tasks are performed by, for example, the Topcon CropSpec sensor system. Sensors installed on this system scan plants in order to detect chlorophyll content, since this indicator correlates with the nitrogen content in plant leaves (CropSpec™ vegetation..., 2019). Such sensors are used to determine the amount of nitrogen in plants in order to determine the doses of accurate fertilizer application. However, we propose the use of such systems to determine the optimal timing of grass harvesting for fodder storage. The flight control system communicates with an assistant installed on a personal computer (PC) via a Micro-USB cable. This allows us to configure UAVs and update their firmware (Agriculture in Russia, 2019). The architecture of a remote monitoring system for crude protein content in perennial grasses (determining the optimal mowing time for

perennial grasses) may include subsystems traditional for similar monitoring (Lupyan *et al.*, 2015): data acquisition subsystem; data processing subsystem; subsystem for maintaining data archives; subsystem of data presentation and analysis; system control and monitoring unit.

Knowing the content of nitrogen (protein) in plants, we can determine the fiber content. This term is called structural carbohydrates (SC) together with lignin, which makes up the cell walls of plants. Structural carbohydrates include pectin, hemicellulose (HC), and cellulose (C) (Bailey, 1973). They are a source of energy for ruminants, which, with the help of the microflora of the gastrointestinal tract, are able to partially digest them. It should also be noted the physiological role of structural substances, which consists in ensuring the normal functioning of the rumination and motor function of the gastrointestinal tract.

How to determine the content of crude fiber in plants? There is an inverse relationship between the crude protein content in plants and the crude fiber content. So, for example, experiments conducted at the V.R. Williams All-Russian Research Institute of Feed on alfalfa showed the following regression equation between the content of crude fiber and crude protein in alfalfa in the flowering phase (Stepanova, 2019):  $Y = -1.5x + 56.6$  (correlation coefficient  $r = -0.83 \pm 0.15$  ( $tr = 5.4$   $9 > t_{01} = 2.98$ )). In the non-chernozem zone of Russia, in the crops of perennial grasses, a significant proportion of cereal grasses such as brome, meadow fescue, and timothy grass meadow occupy a significant share. This species of grasses and feed from them occupy a high share in the feed balance of ruminants. The content of crude fiber and crude protein in these grasses in the conditions of central Russia, depending on the vegetation phase, obtained by the authors of this article, are given in Table 3.

The correlation between crude protein and crude fiber in these grasses are close (Figure 4) (Equation 1):

$$Y = 43.41 - 1.13X \quad (R^2 = 0.844), \quad (\text{Eq. 1})$$

where  $X$  – crude protein content in plants, %;  $Y$  – crude fiber content in plants, %.

#### 4. CONCLUSIONS:

Thus, the nitrogen content determined using remote technology in perennial grasses can serve as a starting point for determining the crude protein content in them, which in turn can serve as the basis for determining the amount of crude fiber

(based on the use of the above regression equation). The period of time when the crude protein content is 16-18%, and the fiber content 26-28% will be the optimal mowing period for perennial grasses.

Digital technologies are firmly entering our lives and are more often being used in field agriculture. The use of unmanned aerial vehicles equipped with powerful infrared sensors allows us to quickly, within a few hours, determine not only the nitrogen content but also the crude protein content in feed crops. Using the correlation and regression dependencies between the content of crude protein and crude fiber in plants, it is possible to determine the optimal harvesting time of perennial grasses for hay, silage, and haylage, which will increase the efficiency of feed use, reduce the unit costs of meat and dairy cattle breeding, and increase their efficiency.

**RESUMO**

Nos últimos anos, o protozoário parasitário *Blastocystis* spp., que habita o trato gastrointestinal humano, começou a atrair cada vez mais atenção dos parasitologistas. Uma alta incidência de contaminação por blastocisto foi revelada em indivíduos de vários grupos populacionais. Neste artigo, os resultados do estudo mostram altas taxas de invasão de trabalhadores de fundição pelo protozoário mencionado acima, caracterizado por condições perigosas de trabalho, tanto de natureza física quanto química. A capacidade dos protozoários de habitar um nicho ecológico específico depende de suas propriedades biológicas; assim, fatores de persistência são de particular interesse. O artigo descreve o potencial persistente do *Blastocystis* spp., habitando o intestino humano. As propriedades persistentes nos procariontes são um fator fisiológico significativo para a sua existência e determinam o mecanismo de interação dos microrganismos que formam a microflora intestinal. Foi estudado o complexo de fatores de persistência (ALA, ALFA e AHA) do *Blastocystis* spp. Foi encontrada uma correlação direta entre a atividade persistente dos blastocistos e a gravidade dos distúrbios da microbiocenose intestinal. O efeito de fatores desestabilizadores da produção que levam à reestruturação do bioma intestinal foi estabelecido, contribuindo para a diminuição do grupo nativo de microrganismos e para o aumento da flora oportunista. Os dados recebidos permitem utilizar as propriedades biológicas mais importantes da sobrevivência dos microrganismos para estudar os mecanismos de formação de microsimbiocenoses no biótopo do intestino grosso e são um pré-requisito teórico para o desenvolvimento de um método de rastreamento do diagnóstico de disbiose intestinal com base na determinação de ALA, ALFA e AHA de isolados clínicos de blastocistos.

**Palavras-chave:** *microbiocenose, parasitocenose, distúrbios disbióticos, antiliscito, antilactoferrina.*

**ABSTRACT**

In recent years, the parasitic protozoan *Blastocystis* spp., inhabiting in the human gastrointestinal tract, has begun to attract more and more attention on the site of parasitologists. A high incidence of blastocyst contamination was revealed in individuals of various population groups. In this paper, the results of the study showing high rates of invasiveness of foundry workers by the above-mentioned protozoan, characterized by hazardous working conditions of both physical and chemical nature. The ability of protozoa to inhabit a particular ecological niche depends on their biological properties; thus, persistence factors are of particular interest. The article describes the persistent potential of *Blastocystis* spp., inhabiting the human intestines. Persistent properties in prokaryotes is a significant physiological factor for their existence and determine the mechanism of interaction of microorganisms that form the intestinal microflora. The complex of persistence factors (ALA, ALFA, and AHA) of *Blastocystis* spp. was studied. A direct correlation between the persistent activity of the blastocysts and the severity of intestinal microbiocenosis disorders was found. The effect of destabilizing production factors leading to the restructuring of the intestinal biome has been established, contributing to a decrease in the indigenous group of microorganisms and an increase of opportunistic flora. The received data allow using the most important biological properties of the survival of

the microorganisms to study the mechanisms of microsymbiocenoses formation of in the biotope of the large intestine and are a theoretical prerequisite for developing a method for screening diagnosis of intestinal dysbiosis based on the determination of ALA, ALFA and AHA of clinical blastocyst isolates.

**Keywords:** *microbiocenosis, parasitocenosis, dysbiotic disorders, antilysocyme, antilactoferrin.*

## АННОТАЦИЯ

В последние годы все большее внимание паразитологов стал привлекать паразитический простейший организм *Blastocystis* spp., обитающий в желудочно-кишечном тракте человека. Выявлены высокие показатели обсемененности бластоцист у лиц различных групп населения. В настоящей работе представлены результаты исследования, регистрирующие высокие показатели инвазированности данными простейшими рабочих литейного производства, характеризующиеся опасными условиями труда как физической, так и химической природы. При этом способность простейших к заселению той или иной экологической ниши зависит от наличия у них биологических свойств, в этом плане несомненный интерес представляют факторы персистенции. В статье представлена характеристика персистентного потенциала простейшего *Blastocystis* spp., населяющего кишечник человека. Наличие персистентных свойств у прокариот является чрезвычайно важным физиологическим аспектом их существования и определяет механизм взаимодействия микроорганизмов формирующих микрофлору кишечного тракта. Изучен комплекс факторов персистенции (АЛА, АЛФА и АГА) простейших *Blastocystis* spp. Обнаружена прямая корреляционная зависимость между персистентной активностью бластоцист и глубиной нарушений микробиоценоза кишечника. Установлено действие дестабилизирующих факторов производства, которые ведут к перестройке кишечного биома, способствуют уменьшению индигенной группы микроорганизмов и увеличению условно-патогенной флоры. Эти материалы позволяют использовать важнейшие биологические свойства выживания микроорганизмов для исследования механизмов формирования микросимбиоценозов в биотопе толстого кишечника и являются теоретической предпосылкой для разработки способа скрининговой диагностики кишечного дисбиоза, основанного на определении АЛА, АЛФА и АГА клинических изолятов бластоцист.

**Ключевые слова:** *микробиоценоз, паразитоценоз, дисбиотические нарушения, антилизозимная, антилактоферриновая.*

## 1. INTRODUCTION

The general transformation of the influence of environmental conditions in modern society is evident. A lot of abiotic and biotic factors, including anthropogenic ones, affect human health (Sharapov, 2012). The effects of industrial environmental factors on the body should not be ignored. Industries characterized by hazardous working conditions can be determined. This entirely concerns foundry. In a foundry, harmful factors of both physical and chemical nature are inherent (Soloviev, 2013). Physical factors include vibration, noise, high temperature, ultrasound, ionizing radiation; chemical factors include the influence of isocyanates, formaldehyde, tertiary amines such as dimethylethylamine, triethylamine, silicon dioxide, metal oxides. All of the above factors produce favorable conditions for different diseases (Lazarenkov and Khoreva, 2016).

Literature analysis showed that vibration causes changes in cardiac activity, in the nervous system, spasms of blood vessels, changes in the

joints, limiting their mobility (Turovets *et al.*, 2015). Studies of the noise effect on the human body also revealed changes in the functioning of the nervous and cardiovascular systems (Afanasova *et al.*, 2010). During the examination, workers exposed to noise, often complain of irritability, headaches, drowsiness, increased fatigue, poor sleep, dizziness. Persons constantly in contact with the noise of varying degrees and duration revealed disturbances of thermoregulation, increased pulse levels, and blood pressure (Izmerova and Denisova, 2003). Chemical factors inhibit hemopoiesis, disturbs metabolism, and causes functional changes in the nervous system and gastrointestinal tract (Denisov *et al.*, 2010).

Studying the influence of environmental factors on the human body is not a new problem. However, the influence of the entire spectrum of foundry factors on the microbiome of the worker's body is still not completely studied. Intestinal flora serves as an indicator of the microorganisms state, and when exposed to destabilizing environmental factors, its qualitative and quantitative change occurs, indigenous flora

decreases, and opportunistic pathogenic group increase (Kuvaeva and Ladodo, 1991).

In the last decade, many authors have shown the role of opportunistic microorganisms in the occurrence of intestinal infections. The epidemiological situation on parasitic diseases is especially acute; more than 1.3 million patients with various parasitoses are officially registered annually in the country. However, the incidence of parasitic infestations and their importance for public health and the country as a whole remains underestimated for a number of reasons. The reasons for the preservation of such a situation are the difficulties of specific diagnostics, lack of a clear system for recording the incidence rate, insufficient knowledge of doctors, and misunderstanding of both doctors and the population in the field of diagnosis and treatment of parasitoses.

*Blastocystis* spp is the most widespread among the parasitic microorganisms. (Abe, 2004; Dogruman, 2009). According to the classification of microorganisms, this protozoan belongs to the kingdom of Stramenopiles (synonym Chromista, Heterokonta), subdomain Chromobiota, subtype Opalinata, class Blastocystea, order Blastocystida, family Blastocystidae, genus Blastocysts (Hameed, 2011).

The growing interest of scientists and practical parasitologists in this protozoan is explained by its spread in the world. It is found in 30–50% of the inhabitants of developing countries and in 1.5–10% of developed countries (Iguchi, 2007; Jones, 2009; Meloni *et al.*, 2011). Besides, blastocysts are often present in patients with gastroenterological diseases, allergies. For example, due to Horiki *et al.* (1999), in examining a practically healthy population from Tokyo (Japan), blastocysts were found in 7.4% of cases (Horiki, 1999), and in similar studies in Perm, performed by N. M. Koza *et al.* in 1997 - 2001, the blastocystic invasion was revealed in 13.1% of cases (Koza *et al.*, 2002). In Omsk, according to the results of population surveys in 1999 – 2001, the rate of *Blastocystis hominis* detection in healthy persons was within 0.9 – 2.3% (Starostina *et al.*, 2002).

However, in clinical practice, laboratory assistants often do not register blastocysts in the test material. This is explained by the fact that the pathogenic nature of protozoan remains controversial, and, therefore, the registration of the results is not mandatory, and also by inadequate knowledge of laboratory assistants of this object.

It was established that blastocysts have a significant effect on the formation of microbiocenosis of the human intestine, accompanied by a decrease in the seeding rate of indigenous flora (bifidobacteria and lactobacilli), and an increase of opportunistic flora. It was shown that the disturbance of biocenotic relations between pathogenic bacteria and normal intestinal microflora is one of the factors affecting the development of many diseases, especially those with a chronic course. Experimental data confirm a high incidence of blastocysts in individuals with liver diseases, gastric ulcers, and dermatoses (Krasnoperova, 2009).

The discovery of microorganisms belonging to the group of protozoa in the intestinal biome does not always testify to their role in the formation of the studied biotope, and it is absolutely impossible to assess their significance for a macroorganism experiencing constant pressure from a complex of factors of an unfavorable industrial environment, which reduces the protective forces of the human body and makes him vulnerable to various forms of the disease.

Human normoflora provides non-specific resistance of a macroorganism (Tsimmerman, 2014). Microorganisms colonizing the intestine prevent contamination of the mucous membranes of the digestive tract with opportunistic microorganisms, using a large group of secreted bacterial substances as a defense against the pathogen. Conventionally pathogenic flora is present in the intestines of healthy people as additional or transient representatives in certain quantitative and qualitative indicators (Blaser and Falkow, 2014; Kuchumova, 2011).

Thus, in determining the etiological significance of the conventionally pathogenic flora, to which the group of parasitic protozoa *Blastocystis* spp can be attributed, along with their number, factors contributing to persistence must be taken into account, which are considered as a marker that determines the long-term habitation of the pathogen in the host organism. These traits include the ability of microorganisms to degrade lysozyme - antilysozyme activity (ALA), the ability to inactivate lactoferrin - antilactoferrin (ALPA), and antihistamine (AHA) activity.

The purpose of the study was to give a comparative characteristic of the persistent potential of parasitocenosis of the human intestine, under the influence of a complex of unfavorable factors in the working environment.

To achieve this purpose, the following tasks were set:

1. To study microbiocenosis characteristics in human large intestine under the influence of a complex of destabilizing factors of the working environment.
2. To determine the occurrence of protozoa *Blastocystis* spp. in the intestines in norm and in dysbiosis.
3. To study blastocysts biological properties using antilysocyme, antilactoferrin, and antihistone activities as an example.

## 2. MATERIALS AND METHODS

A series of studies on the intestinal microbiocenosis in persons working in the foundry of the Armature Plant were performed at the clinic of OJSC "Reinforcing Plant", the Helix laboratory and the research laboratory "Diagnostics" in St. Petersburg.

To assess the microbiocenosis, the method of quantitative isolation of types and variants of microorganisms that make up the microbiocenosis according to the order of the Ministry of Health of Russia of 09.06.2003 No. 231 "On approval of the industry standard "Protocol for the management of patients. Intestinal dysbiosis" (OST 91500.11.0004-2003) was used.

Cultures grown on culture media were subjected to group, generic, and species identification.

The inoculation and incubation on solid media for the isolation of lacto- and bifidumbacteria was carried out in anaerostats AE-01 (OJSC NIKI MLT, St. Petersburg) and OXOID (England) using Anaerogaz gas-generating packages. Anaerobic microorganisms were identified using ANAEROTEST 23 (Lachema, Czech Republic). Identification of opportunistic enterobacteria was carried out using general identification schemes. Identification of opportunistic enterobacteria was performed following generally accepted identification schemes using PBDE (Diagnostic Systems, Nizhny Novgorod), ENTEROTEST 24 (Lachema, Czech Republic), NEFERMtest (Lachema, Czech Republic), and Giss mediums. Yeast-like fungi, genus *Candida*, were revealed by their ability to assimilate carbohydrates using the API 20C AUX system (bioMerieux, France).

To detect protozoa, including blastocysts,

both traditional parasitological diagnostic methods (microscopy of fecal smears) and molecular biological methods (PCR) were used. Microscopy of stool smears stained with Lugol solution was carried out in compliance with all requirements for the preparing of preparations (Guidelines 4.2.735-99 "Parasitic methods of helminthism and protozoal diseases laboratory diagnostics" improved by the chief state sanitary doctor of the Russian Federation)

Pavlova and Zierdt media were used to obtain protozoa *Blastocystis* spp. cultures. Persistence factors of microorganisms were studied from 2015 to 2017 at the Institute of Cellular and Intracellular Symbiosis of the Ural Branch of the Russian Academy of Sciences, Orenburg (IKVN Ural Branch of the Russian Academy of Sciences).

Microorganisms persistence factors were studied using research methods proposed by O.V. Bukharin et al. To study microorganisms antilysocyme activity (ALA) the photometric method was used [23]. *Blastocystis* spp. test culture was grown in a liquid nutrient medium, the supernatant was separated and mixed with lysozyme, while preparing a control. The test sample and control were mixed with a suspension of the *Micrococcus lysodeikticus* test culture (strain No. 2665, L.A. Tarasevich GISK), and antilysocyme activity was determined by the optical density of the resulting mixtures, characterized in that the control used a mixture of nutrient broth with lysozyme, incubated the supernatant with lysozyme, introduced the incubated mixture into a pre-treated Trilon B test culture and measuring the optical density of the experimental sample and control in 2 and 4 hours, then calculated antilysocyme activity according to the formula:

$$K = \frac{V_K - V_L - C_L \cdot (M_{O4} - M_{O2})}{M_{K4} - M_{K2}}$$

where K is the coefficient of blastocysts antilysocyme activity;  $V_K$  - the volume of the broth culture of the studied strain;  $V_L$  is the volume of lysozyme solution in the initial concentration;  $C_L$  - lysozyme concentration;  $M_{O4}$  is the average optical density of experimental wells with a broth culture of the studied strain with lysozyme after 4 hours of incubation, units optical density;  $M_{O2}$  is the average optical density of experimental wells with a broth culture of the studied strain with lysozyme after 2 hours of incubation, units optical density;  $M_{K4}$  - the average value of the optical density of control wells with a broth culture of the studied strain without lysozyme after 4 hours of incubation, units optical density;  $M_{K2}$  - the

average optical density of the control wells with a broth culture of the studied strain without lysozyme after 2 hours of incubation, units optical density; 100 - conversion factor.

Microorganisms antilactoferrin activity (ALFA) of was studied according to the method described O.V. Bukharin et al. [24]. The amount of lactoferrin was determined by the method of enzyme-linked immunosorbent assay using sets of "Lactoferrin-strip", CJSC "Vector - Best", Novosibirsk. Test culture *Blastocystis* spp. was grown on solid nutrient medium; a microbial suspension was prepared from the grown agar culture, mixed with lactoferrin, while preparing a control., a liquid nutrient medium was added to the control instead of a microbial suspension. The test sample and control were incubated, the supernatant was separated from the simple blastocyst cells by centrifugation, determining the concentration of lactoferrin in the experimental and control samples by enzyme immunoassay and then calculate ALfa according to the formula:  $ALFA = Ck - Co$ ,

where: ALFA - antilactoferrin activity, ng of inactivated lactoferrin / ml supernatant; Ck is lactoferrin concentration in the control, ng / ml; Co - lactoferrin concentration of in the experiment, ng / ml.

The antihistone activity of the studied microorganisms was determined by the photometric method [25]. To do it histone preparation from bovine thymus manufactured by Sigma (USA) in the form of a lyophilized powder containing a total fraction of histones was used. Test *Blastocystis* spp culture. grown in a liquid nutrient medium, was treated with chloroform, the culture fluid was separated, mixed with histone solution, simultaneously preparing two control samples. Isotonic NaCl solution was added in Control 1, instead of histones solution, and in control 2 liquid nutrient medium was added instead of culture fluid. The experimental and control samples were incubated, after incubation, the meat-peptone broth and the *Micrococcus luteus* test culture (GISK 211001) were added to all samples, re-incubated, the optical density of the suspensions was measured in the experiment and controls, then antihistone activity was calculated be the formular

$$\left( \frac{oDts - oDc1}{oDc1 - oDc2} \right) * 12.84 mcg / ml$$

where: oDts -optical density of the test sample; oDc1 -optical density of control1; oDc2 – optical density of control 2.

### 3. RESULTS AND DISCUSSION

The study was performed in 129 workers of the enterprise aged from 25 to 55. The control group consisted of 50 healthy m. persons.

Analysis of outpatient cards, record cards with the results of periodic medical examinations for the period from 2013 to 2017, revealed a number of diseases in the studied group. Vibration disease was on the first place ( $78.30 \pm 2.7\%$ ), diseases of the hearing organs were registered in  $43.20 \pm 3.2\%$  of workers, diseases of the nervous and cardiovascular systems in  $32.40 \pm 3.4\%$  and  $28.6 \pm 1.3\%$ , respectively, acute respiratory infections in the mean of  $19.20 \pm 1.8\%$ , diseases of the musculoskeletal system in  $8.40 \pm 1.7\%$ . A high percentage of digestive organs diseases were registered, their rate was  $62.30 \pm 3.6\%$  (80 persons).

The gastrointestinal tract plays a significant role in the human body since the main physiological processes occur there. Therefore, the proper functioning of the human digestive system serves as the basis for normal and full life support. The question of the influence of industrial and technical factors on the microbiome of the human body, which actively performs many functions that provide homeostasis, is still not clear. So monitoring of human health under the influence of unfavorable factors of the working environment and their influence on the digestive system of the body was performed.

In this connection, studied subjects were divided into three groups, depending on the duration of contact with destabilizing industrial factors. The first group consisted of employees working at the enterprise from 1 to 5 years - 26 persons ( $32.5 \pm 2.7\%$ ,  $p < 0.03$ ), the second included those who worked at the enterprise from 5 to 10 years - 32 people ( $40.0 \pm 3.9\%$ ,  $p < 0.05$ ), the third group consisted of employees working at the enterprise 10-15 years and more - 22 persons ( $27.5 \pm 1.4\%$ ,  $p < 0.03$ ).

Diagnosis of the qualitative and quantitative composition of the intestinal microbiocenosis of the examined patients showed disturbances on the part of normoflora. Besides, a decrease in the occurrence of the representatives of obligate microflora was shown: bifidobacteria and propionic bacteria to  $85.4 \pm 3.4\%$ ,  $81.3 \pm 3.1\%$ , respectively ( $p < 0.05$ ), lactobacilli to  $77.4\% \pm 4.3$  ( $p < 0.03$ ), bacteroids up to  $87.5 \pm 3.9\%$ , ( $p < 0.05$ ), non-hemolytic *E. coli* up to  $68.3 \pm 2.9\%$ , ( $p < 0.05$ ). In the control group, these figures were within the range of 98-100% ( $p < 0.03$ ). A decrease in the density of

colonization was observed in these groups of microorganisms, for example, for bifidobacteria, it averaged  $\log 6.4 \pm 0.4$  CFU/g, for lactobacilli and bacteroids,  $\log 7.0 \pm 0.1$  CFU/g and  $\log 8.5 \pm 0.1$  CFU/g, respectively ( $p < 0.05$ ).

Depending on the duration of work in the foundry, the frequency and density of colonization of obligate endoflora representatives varied among workers of the 2nd group, reaching maximum deviations from the normocenosis in the examined from the 3rd group. The most visible disorders in the obligate group of microbes were noted among the workers with more than ten years of work experience. The seeding rate in relation to the bifidobacteria group was  $\log 5.3 \pm 0.2$  CFU/g, for lactobacilli  $\log 6.2 \pm 0.1$  CFU/g, which is significantly lower than in the comparison group. In the control group, the seeding rate for bifidobacteria and lactobacilli was  $\log 10.5 \pm 0.3$  CFU/g and  $\log 9.9 \pm 0.4$  CFU/g, respectively ( $p < 0.05$ ).

The occurrence of opportunistic flora increased depending on the duration of the technogenic factors of the production environment action. High colonization density was observed for bacteria genus *Enterococcus* spp., *Proteus* spp., *Staphylococcus* spp., and fungi genus *Candida* spp. Their dissemination rates were significantly higher in comparison with the control group and amounted on average to  $1g 10.2 \pm 0.3$  CFU/g,  $\log 2.6 \pm 0.4$  CFU/g,  $\log 5.0 \pm 0.3$  CFU/g and  $\log 4.5 \pm 0.4$  CFU/g, respectively ( $p < 0.05$ ). In the control group, these figures were as follows:  $\log 2.5 \pm 0.3$  CFU/g,  $1g 0.9 \pm 0.4$  CFU/g,  $1g 2.3 \pm 0.3$  CFU/g and  $1g 2.4 \pm 0.4$  CFU/g, respectively ( $p < 0.05$ ). The occurrence and the density of colonization of opportunistic microbes were directly dependent on the length of service at the enterprise.

A significant increase in the content of *Escherichia coli* with hemolytic activity should be stressed. This indicates their high pathogenicity compared with the control group.

At present, much attention is paid to the importance of colonic dysbiosis in parasitoses. So, besides representatives of the bacterial flora, an assessment of the intestinal parasitocenosis was performed in the subjects studied. *Blastocystis* spp. ( $62.00 \pm 5.4\%$ ), *Lambli* *intestinalis* ( $36.72 \pm 3.2\%$ ) and *Entamoeba coli* ( $16.34 \pm 1.3\%$ ) prevailed as to the frequency of their occurrence.

Studies have shown that, depending on the duration of work in the foundry, the detection of blastocysts in the feces of workers increases

from  $56.30 \pm 4.6\%$  in the first group to  $85.63 \pm 7.8\%$  in the third group.

A study of the biological properties of *Blastocystis* spp., colonizing the mucous membranes of the large intestine, will allow developing new approaches to assessing the participation of this pathogen in the development of the pathological process, explain the possible reason for the presence of blastocysts in the studied biotope and determine the participation of these protozoa in the formation of the intestinal biome in the persons under study.

Blastocyst strains isolated from the intestines of foundry workers were selected as a material for the study. All the subjects were divided into four groups depending on the severity of dysbiotic disorders (Table 1).

To date, there is no universally accepted classification of intestinal dysbiosis. Classification Intestinal flora dysbiosis, proposed by G. Kuznetsova (1972), was used in this work. It includes 4 degrees of colonic dysbiosis severity: stage I showed a decrease in the number of bifidobacteria and lactobacilli, stage II was characterized by a pronounced increase and subsequent predominance of colibacterial flora, appearance of atypical and enzymatically defective *E. Coli*, in stage III high titers of optional flora associations (staphylococci, streptococci, clostridia, fungi of the genus *Candida*, etc.) were registered while bifidobacteria and lactobacilli decreased on this background and stage IV with a predominance of *Proteus* or *Pseudomonas aeruginosa* prevalence.

With an increase in work experience from 1 to 15 years or more, the factors of dysbiotic manifestations increased, characterized by quantitative and qualitative values of microorganisms underlying the determination of dysbiosis of varying severity.

The studies performed allowed to determine the quantitative composition of the blastocyst strains isolated from the examined individuals, depending on the degree of intestinal dysbiosis (Table 1).

The greatest number of *Blastocystis* spp. was found in individuals with dysbiotic changes of the II degree of severity - 28 strains ( $47.50 \pm 1.7\%$ ,  $p < 0.03$ ).

The control group (50 people) consisted of persons undergoing outpatient treatment and not contacting the harmful factors of the working environment. The data obtained above were analyzed considering the questionnaire survey, in

which the persons of the comparison group participated. In persons from this group, dysbiosis of varying severity was observed in 4.0 0.7%,  $p < 0.03$ , blastocyst invasion in 12.0 0.2%,  $p < 0.03$  (6 people).

The study of biological properties was carried out on the example of ALA, ALPA, and AGA activities, which are quite widely represented in the group of opportunistic bacteria. However, the study of these traits in *Blastocystis* spp., isolated in individuals exposed to destabilizing factors of foundry and aggravated by gastrointestinal diseases, was not yet carried out.

The role of lysozyme in protecting the macroorganism from infection is well known. Antilysozyme activity is one of the factors that increase the tolerance of microorganisms to the action of human and animal serum lysozyme. Some authors believe that antilysozyme activity contributes to the long-term survival of microorganisms in a macroorganism and can be used in bacteriological laboratories to assess the etiological role of isolated cultures.

Of the 62 studied blastocyst strains, 56 ( $89.28 \pm 5.7\%$ ) possessed the studied trait. To analyze persistent characteristics of *Blastocystis* spp. Three groups of protozoa were chosen: the first included strains with a low ALA level - up to 2  $\mu\text{g} / \text{ml}$  inclusive, the second with a mean ALA level of 3-4  $\mu\text{g} / \text{ml}$ , and the third with a high ALA level - 5  $\mu\text{g}/\text{ml}$  or more. The proportion of strains with low ALA values was  $33.92 \pm 2.3\%$  (19 strains), with mean ALA -  $50.01 \pm 4.6\%$  (28 strains) and  $16.07.23 \pm 1.7\%$  (9 strains) with high ALA values (Table 2).

Table 3 shows that half of the blastocyst strains ( $50.01 \pm 4.6\%$ ) isolated from the workers had average antilysozyme activity values within the range of 3-4  $\mu\text{g}/\text{ml}$ . The proportion of *Blastocystis* spp. isolates with low and high values of the studied trait were  $33.92 \pm 2.3\%$  and  $16.07 \pm 1.7\%$ , respectively.

The performed studies revealed a direct dependence of the ALA blastocysts manifestation on the severity of dysbiotic changes (Table 3).

Thus, blastocysts isolated in individuals with grade I dysbiosis were characterized to a greater extent by low ALA levels, which amounted to  $2.1 \pm 0.02 \text{ mg}/\text{ml}$ , while protozoa strains with grade III and IV dysbiosis had completely no low values of the studied trait. Increased ALA levels in blastocysts were observed with more pronounced factors of

intestinal dysbiotic disorders in workers. Among the nine protozoa strains isolated in dysbiosis of the IV degree of severity, two strains were characterized by mean ( $2.3 \pm 0.02 \text{ mg}/\text{ml}$ ) and seven strains ( $2.7 \pm 0.05 \text{ mg}/\text{ml}$ ) high level of the studied property.

Such an increase in the expression of antilysozyme activity in different degrees of dysbiosis is due to the fact that during biocenosis, which is characterized by a high content of opportunistic flora and a sharp decrease in obligate representatives (IV degree of dysbiosis), an inflammatory state of the intestinal mucosa is observed, which is accompanied by the increased concentration of endogenous lysozyme, intensely secreted by exocrinocytes of the colon in response to increased colonization of the digestive tract by optional microorganisms. It can be assumed that assimilating the ecological niche of *Blastocystis* spp. they produce lysozyme, necessary for the formation of biocenosis, which can lead to a compensatory ALA increase in representatives of the obligate group.

The antilactoferrin activity (ALFA) of protozoa was studied. Data on ALFA prevalence and severity in *Blastocystis* spp., isolated in foundry workers, show that the studied protozoa are highly able to inactivate lactoferrin. Antilactoferrin activity was revealed with a frequency of  $69.35 \pm 3.7\%$  (43 strains).

Prevalence of ALFA *Blastocystis* spp. ranged from 65 to 289  $\text{ng}/\text{ml}$  (Table 4). Depending on the parameters of the studied property, all the studied strains were divided into three groups.

The first group of blastocyst cultures had low values of the studied trait, which were in the range of  $65-161 \pm 22.2 \text{ ng}/\text{ml}$ , the second - means -  $162-223 \pm 30.7 \text{ ng}/\text{ml}$  and the third high -  $224-289 \pm 49.3 \text{ ng}/\text{ml}$ . An analysis of the quantitative relations of the studied characteristic showed that almost half of the blastocyst strains were characterized by an average ALFA value ( $45.51 \pm 2.3\%$ ).  $32.56 \pm 2.7\%$  and  $20.93 \pm 3.7\%$  of the studied strains showed, respectively, high and low ALFA values.

As the studies showed, the number of blastocyst strains with high persistent properties had a low percentage of occurrence or was completely absent in dysbiosis of I and II degrees of severity (Table 5). Thus, ALFA analysis showed that protozoa strains isolated in those examined with I degree of dysbiosis had neither mean or high level of the studied trait. In this group, only one strain of blastocysts was

characterized by a low value ( $65-161 \pm 22.2$  ng/ml) of the trait.

In the III degree of intestinal dysbiosis, approximately there was the same number of strains, both with mean and low values of the trait. It should be noted that in significant disturbances of the qualitative and quantitative intestinal microflora composition, characterized by an IV degree of dysbiosis, only blastocyst strains were obtained in the experiment that inactivated lactoferrin in high concentrations of the studied persistent property in 11 isolates.

Of the 62 blastocyst strains, 32 *Blastocystis* spp. isolates, isolated from feces of workers, with the pathology of the gastrointestinal tract, had antihistone activity.

The values of antihistone activity ranged from 1.3-12.8 ng/ml, and in mean, were  $9.1 \pm 1.6$  ng/ml. The results obtained in the experiment allowed to divide all the studied blastocyst strains into three groups (Table 6).

The determination of the AHA level revealed in the vast majority of protozoa low ( $1.3-5.3 \pm 0.9$ ) and mean ( $5.7-9.1 \pm 4.3$  ng/ml) values of the studied trait. Such cultures accounted for 89.28 3.9% of the studied blastocyst strains. The third group consisted of blastocyst strains with high AHA values ( $9.2-12.8 \pm 4.6$  ng/ml) (Table 7).

The number of blastocyst strains isolated from feces of persons in contact with harmful factors of the working environment without obvious dysbiotic disturbances (I degree of dysbiosis) showed the prevalence of protozoa strains with a number of manifested AHA traits. On the contrary, a high level of antihistone activity was observed in blastocyst strains isolated in individuals with dysbiotic changes of moderate and high severity.

Thus, blastocyst strains isolated from feces of individuals exposed to destabilizing factors of the working environment are capable of inactivating certain factors of the natural anti-infection resistance of the microorganism (ALA, ALFA, and AHA). The results of the study allowed not only to reveal them but also to rank according to the degree of their information content (Figure 1).

The antilysozyme trait is the main persistent trait that determines the formation of the intestinal microbiocenosis of a given biotope. It was recorded with a frequency of  $89.28 \pm 5.7\%$ . Isolated *Blastocystis* spp. strains possess high values of the studied persistent characteristics

(ALA, ALFA, AHA) characterizing their persistent activity.

These traits contribute to the displacement of the dominant symbionts of the intestinal flora by blastocysts, colonization of mucous membranes by the protozoa studied, and leads to the formation of special parasitocenosis.

Since *Blastocystis* spp. possess a wide range of persistent symptoms, the question arises on protozoal infection of the macroorganism cell nucleus, and it is possible to confirm this at the light microscopic level, make an indirect assessment of the morbidity of the population by the occurrence rate of protozoan strains isolated from this contingent of the examined individuals, and also use them to diagnose and predict blastocystosis.

A study of the relationship between the severity of dysbiotic changes and persistent characteristics revealed an increase in the persistent characteristics of blastocysts with an increase in the severity of microecological disturbances in the intestine. The revealed relationship between persistent features of protozoa and the severity of disturbances in the intestinal microbiocenosis made it possible to consider persistence factors as markers of the dysbiotic process.

#### 4. CONCLUSION

The study of the intestinal microbiome in persons working in foundry conditions, characterized by the complex effect of the examined factors of physical and chemical nature on the body, allowed to detect qualitative and quantitative changes in the composition of the normal flora of the large intestine. A decrease in the occurrence of obligate microflora representatives and an increase in the conditionally pathogenic group were registered. Experimental data revealed four severity levels of dysbiotic disorders in individuals of the examined group, which were directly dependent on the length of service at the enterprise. In persons with an experience of 10-15 years or more, in  $73.56 \pm 2.3\%$  ( $p < 0.05$ ) of cases, there were changes in intestinal dysbiosis of the 4th degree. In the control group, no visible changes in the composition of the obliterate representatives were found ( $p < 0.05$ ).

The study of intestinal parasitocenosis of the examined biotope showed the prevalence of the protozoan group *Blastocystis* spp. ( $62.00 \pm 5.4\%$ ). The studies showed that, depending on

the duration of work in the foundry, blastocysts in the feces of workers increases from  $56.30 \pm 4.6\%$  in the first group, where the duration of work ranged from 1 year to 5 years, up to  $85.63 \pm 7.8\%$  in the examined, with experience of 10-15 years or more.

The studies performed allowed to determine the quantitative composition of the blastocyst strains isolated from the examined individuals, depending on the degree of intestinal dysbiosis.

The largest number of protozoa is *Blastocystis* spp. found in the feces of individuals with dysbiotic changes of the II degree of severity - 28 strains ( $47.50 \pm 1.7\%$ ,  $p < 0.03$ ). The data obtained can be interpreted in the context of the fact that the simplest blastocysts, together with a community of other microorganisms, participate in the formation of a special microbiocenosis of the studied biotope, characterized by a decrease in representatives of the obligate flora and a significant increase in the optional one.

The data on a high level of severity of persistent properties of strains of *Blastocystis* spp. were obtained using ALA, ALFA, and AHA as an example. The results of the study allowed not only to detect them but also to rank according to the degree of their information content. The leading persistent trait that determines the formation of the intestinal microbiocenosis of a given biotope is their antilysocyme trait.

An increase in the persistent characteristics of blastocysts with an increase in the depth of microecological disturbances in the intestine was established. The revealed relationship between persistent features of protozoa and the depth of disturbances in the intestinal microbiocenosis made it possible to consider persistence factors as markers of the dysbiotic process.

**RESUMO**

A forma dispersa de comprimidos (ODT) dos medicamentos é conveniente para os pacientes; a eficácia de seu uso aumenta significativamente com o tratamento de não conformidade de transtornos mentais. Após o vencimento da patente do medicamento original, a produção de genéricos com o mesmo ingrediente farmacologicamente ativo geralmente começa. Devido a diferenças nas cargas e nas técnicas de fabricação, mesmo cópias de alta qualidade do produto original podem não ser equivalentes. Portanto, o objetivo deste estudo foi avaliar a bioequivalência da forma ODT do medicamento original e genérico com 10 mg de olanzapina. Depois de consumir o medicamento original e o genérico, em dois estágios, com o estômago vazio de voluntários saudáveis, foram coletadas amostras de sangue venoso em tubos a vácuo com heparina. O período entre as doses dos medicamentos foi de 21 dias. A extração (LLE) da olanzapina foi realizada com uma mistura de n-hexano:isopropanol (3:1) com pH 8,0, e analisada por cromatografia líquida-espectrometria de massa em tandem (armadilha de íons quadrupolo-linear). O grau de extração da olanzapina do sangue (amostras modelo, 20 ng/ml) foi de 75,2% (CV 4,6%). O limite quantitativo para a olanzapina por HPLC-MS/MS (LLOQ) foi de 0,50 ng/ml (CV 2,0%, precisão 17,6%). Os estudos conduzidos em sistema aberto randomizado mostraram um perfil de biodisponibilidade e bioequivalência satisfatório do medicamento original e olanzapina genérica. Os parâmetros farmacocinéticos calculados para os valores médios convertidos logaritmicamente, verificados com um intervalo de confiança de 90%, foram:  $C_{max}$  - 95,93-99,80% (valor médio 97,64%);  $AUC_{0-t}$  - 95,43-100,35% (valor médio 97,75%);  $C_{max} / AUC_{0-t}$  - 94,44-101,73% (valor médio 97,87%).

**Palavras-chave:** olanzapina, comprimido orodispersível, bioequivalência genérica, LC-MS / MS.

**ABSTRACT**

Dispersible tablet form (ODT) of drugs is convenient for patients to take; the effectiveness of its use increases significantly with non-compliance treatment of mental disorders. Upon the expiration of the patent for the original drug, the production of generics with the same pharmacologically active ingredient often starts. Due to differences in fillers and manufacturing techniques, even high-quality copies of the original product may not be equivalent to it. Therefore, the aim of this study was to evaluate the bioequivalence of the ODT form of the original drug and generic with 10 mg olanzapine. After taking the original drug and generic in two stages, on an empty stomach from healthy volunteers, from the vein were sampled bloods into vacuum heparin tubes. The washout period between doses of the drugs was 21 days. The extraction (LLE) of olanzapine was carried with a mixture of n-hexane:isopropanol (3:1) at pH 8.0, and analyzed by liquid chromatography-tandem mass spectrometry (quadrupole-linear ion trap). The degree of extraction olanzapine from bloods (model samples, 20 ng/ml) was 75.2% (CV 4.6%). The quantitative limit for olanzapine by HPLC-MS/MS (LLOQ) was 0.50 ng/ml (CV 2.0%, accuracy 17.6%). Conducted on an open randomized cross scheme studies showed a satisfactory bioavailability and bioequivalence profile of the original drug and generic containing olanzapine. The calculated pharmacokinetic parameters for the logarithmically converted mean values verified with a 90% confidence interval were:  $C_{max}$  - 95.93-99.80% (average value 97.64%);  $AUC_{0-t}$  - 95.43-100.35% (average value 97.75%);  $C_{max} / AUC_{0-t}$  - 94.44-101.73% (average value 97.87%).

**Keywords:** olanzapine, orodispersible tablet, bioequivalence, generic, LC-MS/MS.

## АННОТАЦИЯ

Диспергируемая таблетированная форма (ДТ) лекарственных препаратов удобна для приема пациентами; эффективность ее применения существенно возрастает при нонкомплаенсе лечения психических расстройств. По окончании срока действия патента на оригинальное лекарство часто запускается производство дженериков с тем же фармакологически активным ингредиентом. Из-за различий в наполнителях и технологиях изготовления даже высококачественные копии оригинального препарата могут быть не эквивалентны ему. Поэтому целью данного исследования было оценить биоэквивалентность ДТ формы оригинального препарата и дженерика с содержанием оланзапина 10 мг. После приема оригинального препарата и дженерика в два этапа, натошак у здоровых добровольцев из вены отбирались пробы крови в вакуумные пробирки с гепарином. Период вымывания между дозами препаратов составлял 21 день. Извлечение оланзапина проводили методом жидкостно-жидкостной экстракции смесью н-гексан: изопропанол (3:1) при pH 8,0, анализировали методом жидкостной хроматографии с тандемной масс-спектрометрией (квадруполь-линейная ионная ловушка). Степень извлечения оланзапина из крови (модельные образцы 20 нг/мл) составила 75,2% (CV 4,6%). Предел количественного определения оланзапина методом ВЭЖХ-МС/МС составил 0,50 нг/мл (CV 2,0%, точность 17,6%). Проведенные по открытой рандомизированной перекрёстной схеме исследования показали удовлетворительный профиль биодоступности и биоэквивалентности оригинального препарата и дженерика, содержащих оланзапин. Рассчитанные фармакокинетические параметры для логарифмически преобразованных средних значений верифицированные с 90%-ным доверительным интервалом составили:  $C_{max}$  - 95,93-99,80% (среднее значение 97,64%);  $AUC_{0-t}$  - 95,43—100,35% (среднее значение 97,75 %);  $C_{max}/AUC_{0-t}$  - 94,44-101,73% (среднее значение 97,87%).

**Ключевые слова:** оланзапин, диспергируемая таблетка (ДТ), биоэквивалентность, дженерик, ВЭЖХ-МС/МС.

## 1. INTRODUCTION:

Development of second generation of atypical antipsychotics, such as olanzapine (a thienobenzodiazepine derivative), provided a possibility for new, safer standards of psychiatric disorders treatment (San, Casileas, Ciudad, and Gilaberte, 2011).

Olanzapine binds to serotonin (5-HT<sub>2A/2C</sub>, 5-HT<sub>3</sub>, 5-HT<sub>6</sub>), dopamine (D<sub>1</sub>, D<sub>2</sub>, D<sub>3</sub>, D<sub>4</sub>, D<sub>5</sub>), and muscarinic (M<sub>1-5</sub>) receptors, as well as to  $\alpha_1$ -adrenoreceptors and histamine H<sub>1</sub>-receptors, which predetermines its pharmacological activity. Olanzapine  $C_{max}$  in serum is reached within 5-8 hours; the concentrations (1-20 mg) are changing linearly, proportional to the dose of the drug. The degree of plasma protein binding is high (FB 0.93) (Tolmacheva, 2019).

Orodispersible tablets (ODT) of olanzapine, manufactured using Zydis® technology, provide several advantages over traditional tablets as they increase patient compliance and more comfortable for use in patients who have difficulty swallowing (San, Casillas, and Gilaberte, 2008; Seager, 1998; Sreenivas, Dandagi, Gadad, and Godblou, 2005). It should be noted that olanzapine absorption depends heavily on the manufacturing technology and dosage form composition: particle size and excipients affect both rate and degree of API

absorption, considering that olanzapine dissolves faster in the acidic environment of the stomach than in the neutral environment of saliva (Chauhan, Kadliya, Patel, Patel, and Patel, 2014; Hobbs, Karagianis, Treuer, and Raskin, 2013; Kozlova, Zabolotnaya, and Maslova, 2015; Maher, Ali, Salem, and Abdelrahman, 2016; Sun, McDonnell, and von Moltke, 2018).

Taking into account increasing trends for wider use of generic (reproduced) drugs in the Russian Federation and worldwide, including drugs released in form of generic ODTs, obligatory tests must be performed in order to confirm their bioequivalence to the original drugs (Russian Federation. Federal Law, 2010). Robust and inexpensive, generic drugs are often preferred due to optimal combination of clinical efficacy, safety and lower costs of treatment (Shabelsky, 2015). However, the conclusion about equivalence of the generic and original drug should be based on the results of comprehensive studies (Russian federation. Ministry of Health and Social Development, 2008; Yin *et al.*, 2016; Yu, Lou, Ruon, Jiang, and Chen, 2012).

Now increasingly a highly sensitive and reproducible method liquid chromatography-tandem mass spectrometry has for the quantification olanzapine in whole blood (plasma, serum) (Cavalcanti Bedor *et al.*, 2015; Domingues *et al.*, 2016; Steuer *et al.*, 2015; Ufinovská *et al.*,

2012).

Olanzapine is a weak base (pKa1 5.0; pKa2 7.4, pKa3 14, 7), has a log P 3.0 and strongly binds to blood proteins. Various extraction variants are used to extract olanzapine from blood samples (Nielsen *and* Johansen, 2009; Poothong, Lundanes, Thomsen, *and* Haug, 2017), but the liquid-liquid extraction (LLE) method is simpler to perform and economical. Therefore, in a carried study, a used optimized variant of liquid-liquid extraction a blood sample for analysis olanzapine developed using the special program "ASD/Percepta".

Olanzapine is administered in doses of 5-40 mg / day, the level and time to reach its maximum concentration in the blood varies depending on the dosage form used, and its pharmacokinetic profile is affected by the genotype of the subject (Chen *et al.*, 2012; Citrome *et al.*, 2009; Fan *et al.*, 2020; Markowitz *et al.*, 2006; Polasek *et al.* 2018; Sathirakul *et al.*, 2003).

A critical analysis of the publications showed that patients prefer the dispersible form of the drug and studies are being conducted in different countries to study the bioequivalence of generics from various manufacturers, especially it actual for the often administered doses of olanzapine 10-20 mg/day (Cánovas *et al.*, 2011; Chatsiricharoenkul *et al.*, 2011; Chatsiricharoenkul, 2009; Du *et al.*, 2019; Elshafeey, Elsherbiny, *and* Fathallah, 2009; Sun *et al.*, 2016; Waykar *and* Kulkarni, 2012; Zakeri-Milani, Islambulchilar, Ghanbarzadeh, *and* Valizadeh, 2013).

Therefore, the aim of the study was to compare bioavailability and bioequivalence of a single, orodispersible dose of olanzapine (10 mg), manufactured by Teva Operations Poland Sp.z.o.o. (Olanzapine-DT-Teva, generic drug (T)) and by Catalent U.K. (Zyprexa® Zydis®, original drug, (R)).

## 2. MATERIALS AND METHODS:

### **Reference standards and reagents:**

Olanzapine and clozapine reference standards (RS) ( $\geq 98\%$  purity, HPLC) were purchased from Sigma-Aldrich (USA). Ascorbic acid (pharmacopoeial quality) was purchased from FARM,  $\Phi$ C-42-2668-95. Methanol (HPLC-MS grade), isopropanol, *n*-hexane, formic acid, and ammonium acetate (HPLC grade) were obtained from Merck KGaA (Germany). Deionized water for HPLC analysis was obtained using Barnstead

Easypure II, Model 7134 (Thermo Fisher Scientific, USA) water purification system.

**Instrumentation:** Atom 80 (Biotron, Spain) automatic shaker, Eppendorf 5415C (Eppendorf, Germany) centrifuge, Eppendorf Concentrator 5301 (Eppendorf, Germany). HPLC-ESI-MS/MS was conducted on a Shimadzu (Columbia, MD) HPLC system composed of two LC-20AD pumps with a CTO-20A column oven, DGU-20A3 degasser and CBM 20A controller connected to a SIL20A autosampler all interfaced with an API Sciex 3200 triple quadrupole mass spectrometer (Applied Biosystems/MDS Sciex, Foster City, CA). Analyst 1.6.3 software (AB Sciex, Foster City, CA) was utilized for instrument control, data acquisition, and analyte mass spectrometric parameter optimization.

**Volunteers:** A total of 18 healthy, non-smoking male volunteers (Caucasian, age 18-45) were included in the study after signing informed consent agreement and undergoing medical examination.

**Study design:** An open randomized crossover study was carried out in two stages: a course of original drug was followed by a 21-day washout period, then a course of generic drug. The drugs were administered on an empty stomach. Both drug products during study satisfied manufacturers' quality requirements and were within their shelf-life limits. Blood samples were withdrawn prior to drug administration and 1.0, 2.0, 3.0, 3.5, 4.0, 4.5, 5.0, 5.5, 6.0, 7.0, 8.0, 9.0, 10.0, 12.0, 16.0, 24.0, 36.0, 48.0, 72.0, 120.0, and 168.0 hours after olanzapine administration. Blood samples from cubital vein were collected into vacuum test tubes containing heparin and allowed to stand for 5-10 min before centrifugation. After centrifugation for 10 min at 2500 RPM, separated plasma was transferred into labeled plastic vials. All samples were stored at  $-40^{\circ}\text{C}$  in low-temperature freezer (Sanyo, Japan) until analysis.

**Analytical procedure:** The method of liquid-liquid extraction was developed based on calculations of the physicochemical parameters of olanzapine by the specialized ACD/Percepta program (pKa, LogP, LogD). Also, using this program "ACD/Percepta", an internal standard of clozapine (LogP 3,37) was selected, which has physico-chemical parameters similar to olanzapine (Figure 1 and 2). The selection of the internal standard is very important for the sample preparation and analysis stage, as it allows the sample preparation to rectify the effect of error on the measurement results by correcting it

mathematically (using the ratio).

The LogP distribution coefficient (octanol/water) determines the lipophilicity of the compound and its distribution between two immiscible phases, with different polarity properties. Indices of acidity (pKa) of olanzapine allow to determine optimal solution pH for its dissolution, and LogD characterizing dependence between LogP and pKa was used to achieve maximum extraction of olanzapine (Sanjivanjit, 2019). As can be seen from the figures, the non-ionized form of substances already prevails at a pH above 8, and the change Log D is insignificant. On the basis of the obtained data, a protocol of operational procedures for analysis (SOP) was developed.

In order to extract olanzapine from plasma samples, 2 mcl of clozapine methanol solution (internal standard, 225 ng/ml) were added to 100 mcl of plasma in 2 mL Eppendorf centrifuge test tubes, followed by 25 mcl of 5% ascorbic acid solution, 400 mcl of carbonate buffer (pH 8), 1 ml of n-hexane-isopropanol mixture (3:1), and 150 mg of sodium chloride. The mixture was shaken for 10 minutes using automatic shaker. After that, all samples were centrifuged for 10 min at 12500 RMP. Seven hundred microliters of organic phase were transferred into vial using automatic pipette and were evaporated until dry. Dry residue was reconstituted in 100 mcl of methanol and transferred into glass inserts, which were, in turn, placed into 1,5 ml chromatographic vials. Solutions were analyzed LC-MS/MS. Separation was carried out in gradient mode (mobile phase – 0.10% ammonium acetate (A) and methanol (B), starting with 10% A, flow rate – 0,4 ml/min) on ProntoSIL 120-5-C18 AQ (2.0 x 75 mm) chromatographic column at 40°C. Injection volume – 5 mcl. Olanzapine retention time was 5.37 min (Figure 3).

Detection was performed using M+H values and MRM transition, using main and daughter ions: 313.2/256.2 m/z for olanzapine (Figure 4) and 327.3/270.2 m/z – for clozapine (internal standard, Figure 5). Olanzapine content was determined using internal standard method with automatic integration by standard AB Sciex software (Analyst 1.6.3).

The quantification procedure was validated using several parameters presented in table 1 to prove its suitability for bioequivalence studies.

Thus, the results obtained comply with the requirements of GOST, EMA, FDA and EURASES Validation Guides (European Medicines Agency, 2011; USA. Food and drug Administration, 2018;

GOST R 56431-2015; Collegion of the eurasian economic commission, 2018) and the technique was found to be suitable for quantitative determination of olanzapine in the blood. Then concentration of olanzapine in blood samples of volunteers was determined validated method as described SOP.

**Pharmacokinetic parameters calculation and statistical data processing:** All calculations were performed using SigmaPlot 12.0 (SYSTAT Software, USA) and Microsoft Excel 2007 (Microsoft, USA).

The following pharmacokinetic parameters were calculated for each participant, using olanzapine concentrations determined after administration of original drug and generic:  $C_{max}$  (maximum measured concentration),  $T_{C_{max}}$  (time until  $C_{max}$ ),  $k_{el}$  (elimination rate constant, which was derived using slope of the final (monoexponential) part of the pharmacokinetic curve, described using non-linear regression analysis),  $T_{1/2}$  (elimination half-life, calculated as natural logarithm (ln) (2)/ $k_{el}$ ),  $AUC_{0-t}$  (area under pharmacokinetic curve from time of administration (0 hours) until final blood sample withdrawal ( $t$  hours); calculated using trapezium rule),  $AUC_{0-\infty}$  (from time of administration to infinity;  $AUC_{0-\infty} = AUC_{0-t} + C_t/k_{el}$ , where  $C_t$  is the last measured drug concentration in plasma),  $AUC_{0-t}/AUC_{0-\infty}$  (this ratio, expressed as per cent, is a measure of adequacy of blood sampling time points),  $C_{max}/AUC_{0-t}$  (relative absorption rate). Consequent analysis of pharmacokinetic data included calculation of relative olanzapine bioavailability after administration of generic drug versus administration of original product ( $f' = AUC_{0-t}(T)/AUC_{0-t}(R)$ ) and calculation of  $f'' = C_{max}(T)/C_{max}(R)$  ratio for each drug. The following descriptive statistics parameters were calculated for all pharmacokinetic values: mean ( $\bar{X}$ ), standard deviation (SD), geometric mean (G), coefficient of variation (CV), median, and maximum (Max) and minimum (Min) values. Values of main pharmacokinetic parameters ( $AUC_{0-t}$ ,  $C_{max}$ , and  $C_{max}/AUC_{0-t}$ ), after logarithmic transformation, were analyzed using ANOVA with  $p < 0,05$ . For common randomized crossover study, statistical model of dispersion analysis included the following factors, which influence observed data variability: drug administration sequence, stages of study, volunteers (within sequence). Dispersion analysis was used to test hypotheses about statistical significance of each of the mentioned factors to the overall variability. Obtained residual variance was used in calculation of 90% confidence interval (CI) for the ratio of mean values of corresponding

parameter.

The conclusion about bioequivalence of compared olanzapine products was based on the assessment of 90% CIs for the ratio of logarithmically transformed mean values of main pharmacokinetic parameters ( $AUC_{0-t}$ ,  $C_{max}$ ,  $C_{max}/AUC_{0-t}$ ). The drugs were considered bioequivalent if 90% CI limits for  $AUC_{0-t}$  and  $AUC_{0-\infty}$  were within 80–125% range. For  $C_{max}$ ,  $C_{max}/AUC_{0-t}$ , and  $C_{max}/AUC_{0-\infty}$  values, which have higher variability, the range was 75–133% (Russian federation. Ministry of Health and Social Development, 2008; Pisarev, Ulyashova, Vdovin, and Tiseyko, 2013).

The study was carried out in accordance with ethical norms, principles of good laboratory practices and good clinical practices, following SOP and study protocol, which were developed in consistence with relevant local regulatory framework (Russian Federation. Federal Law, 2010; GOST 33044-2014; GOST R 52379-2005).

### 3. RESULTS AND DISCUSSION:

Obtained averaged pharmacokinetic curves of olanzapine concentrations in plasma of health volunteers (Figure 6) suggest that the type of the dependence for both studies products is essentially the same.

Using obtained pharmacokinetic curves, individual olanzapine pharmacokinetic parameters ( $C_{max}$ ,  $AUC_{0-t}$  and  $C_{max}/AUC_{0-t}$ ) required for bioequivalence assessment were calculated for each participant. Values of  $AUC_{0-t}$ ,  $T_{C_{max}}$ ,  $k_{el}$ , and  $T_{1/2}$  were also calculated in order to obtain additional information. Mean values of calculated pharmacokinetic parameters and other descriptive statistics parameters are presented in Table 2.

Results of dispersion analysis (Table 3) allowed to accept null hypothesis that the difference in mean values of main pharmacokinetic parameters is not caused by difference in composition or manufacturing technology of the drugs under comparison: the 'Drug' factor (5% level of significance) contributed insignificantly into overall variability of olanzapine pharmacokinetic parameters ( $AUC_{0-t}$ ,  $C_{max}$ ,  $C_{max}/AUC_{0-t}$ ). The critical value for assessing the contribution of drug type factors is value  $F_{0,05;1;17}$  4,45.

The effects due to 'administration period' and 'administration sequence' were also insignificant ( $p < 0.05$ ). Factor 'Volunteer (intra-sequence)' had significant effect on all

pharmacokinetic parameters ( $p > 0.05$ ), but it indicates only intraindividual variability with the volunteer group. Comparison of the obtained data showed that studied olanzapine products do not significantly differ from each other in terms of their pharmacokinetics, and individual values dispersion is identical for both drugs. Mean value ( $\pm SD$ ) of olanzapine relative bioavailabilities ( $f'$ ) after administration of generic drug versus original products was  $0,936 \pm 0.272$  and the ratio of maximum concentrations ( $f''$ ) was  $0,950 \pm 0,099$ .

Calculated 90% CI for the ratios of mean log values of olanzapine  $AUC_{0-t}$ ,  $C_{max}$ ,  $C_{max}/AUC_{0-t}$ , and intraindividual variability coefficients of these parameters are presented in Table 4.

Confidence interval for the ratio of olanzapine log  $AUC_{0-t}$  values was 96,23 - 100,45% (mean = 98.21%); thus, calculated 90% CI is within bioequivalence criteria. Confidence intervals for logarithmically transformed  $C_{max}$  and  $C_{max}/AUC_{0-t}$  values were 95,97 - 99,61% (mean = 97,70%) and 95,83 - 101,87% (mean = 98.60%), also satisfying bioequivalence criteria (Russian federation. Ministry of Health and Social Development, 2008; Romodanovsky, Goryachev, Solovieva, and Eremenko, 2018).

### 4. CONCLUSION:

It was shown that the values of 90% CIs for the ratio of log transformed olanzapine  $AUC_{0-t}$ ,  $C_{max}$ , and  $C_{max}/AUC_{0-t}$  values were 96,23-100,45%; 95,97-99,61%, and 95,83-101,87%, respectively. These results satisfy the currently accepted criteria of bioequivalence, stated in the relevant regulatory documents of the Russian Federation. Therefore, it can be concluded that two studied olanzapine orodispersible dosage forms (10 mg, manufactured by Teva Operations Poland Sp.z.o.o. and by Catalent U.K.) are bioequivalent.

## RESUMO

O artigo descreve o risco químico que pode afetar adversamente o meio ambiente e as pessoas em caso de acidentes em instalações de alto risco, levar à poluição tecnogênica, grandes danos e mortes entre as pessoas. Foi realizada uma análise dos métodos existentes para avaliar os efeitos da contaminação química. As propriedades tóxicas de substâncias tóxicas (ST) foram reveladas. O artigo apresenta o algoritmo de cálculo e o método para prever a situação química após a emissão de ST ou derramamento acidental de substâncias altamente tóxicas (SAT) no ambiente. Mostra-se a sequência de cálculo da solução do problema de avaliação dos parâmetros químicos usando os dados iniciais condicionais. Um programa de computador foi desenvolvido para processar os parâmetros de contaminação química e calcular as perdas entre os funcionários e residentes que possam estar na área de acidentes de indústrias químicas ou emissões para o meio ambiente (de ST, SAT). A análise de cálculos realizados sem o uso do programa de computador para processamento dos parâmetros de contaminação química e de cálculos realizados com o seu uso confirma a confiabilidade do desenvolvimento com base no produto de software Microsoft Visual Studio (Visual C#). É proposto o método de cálculo e avaliação da situação química após acidentes e destruição nas instalações da indústria química. Descreve-se a aplicação prática do programa de computador desenvolvido, que permite que especialistas no campo da defesa civil (DC) realizem os cálculos mais rapidamente para determinar o grau de estabilidade vertical do ar, profundidade e área da nuvem química, tempo de sua chegada ao assentamento, perda de pessoal e população, para tomar decisões mais rapidamente, tanto em tempos de paz quanto em períodos especiais. O artigo apresenta as conclusões sobre os cálculos e os resultados obtidos na resolução de problemas de avaliação de situações químicas utilizando tecnologias modernas.

**Palavras-chave:** *exposição a substâncias perigosas, toxicidade relativa, eliminação das consequências de acidentes, características quantitativas da toxicidade, danos a objetos quimicamente perigosos.*

## ABSTRACT

The article describes a chemical hazard that can adversely affect the environment and humans in the event of accidents at high-risk facilities, lead to man-made pollution, large casualties and deaths. The existing methods of assessment of the effects of chemical contamination were analysed. The toxic properties of poisonous substances (PSs) have been revealed. The calculation algorithm has been presented and the technique for the prediction of the chemical situation after the release of explosive or emergency spills, highly toxic substances (HTS) into the environments has been disclosed. The sequence of solution calculation of the estimation of chemical parameters problem using conditional initial data has been shown. A computer program has been developed to handle the parameters of chemical contamination and to calculate losses among working personnel and residents who may end up in the accident zone of chemical industry facilities or into the environment (PS, HTS). The analysis of the calculations without the use of a computer program for processing chemical parameters

of contamination and using it confirms the reliability of its design based on the Microsoft Visual Studio software (Visual C#). The method of calculation and estimation of a chemical situation after accidents and destruction at chemical industry facilities has been offered. The practical application of the developed computer program has been described, which enables the specialists in the field of civil protection (CP) to make calculations more quickly to determine the degree of vertical stability of air, depth and area of distribution of chemical cloud, time of reaching the settlement, losses of both working personnel and population, more promptly to make decisions both in peacetime and in a special period. Conclusions were made regarding the calculations performed and the results obtained when solving the problems of chemical situation estimation using modern technologies.

## АНОТАЦІЯ

У статті описана хімічна небезпека, яка може негативно вплинути на оточуюче середовище та людей при виникненні аварій на об'єктах підвищеної небезпеки, призвести до техногенного забруднення, великих збитків та смертельних випадків серед людей. Проведений аналіз існуючих методик оцінки наслідків хімічного зараження. Розкриті токсичні властивості отруйних речовин (ОР). Приведений алгоритм розрахунку та розкрита методика щодо прогнозування хімічної обстановки після викиду ОР або аварійного розливу, сильнодіючих отруйних речовин (СДОР) у навколишнє природне середовище. Показана послідовність розрахунку рішення задачі оцінки хімічних параметрів з використанням умовних вихідних даних. Розроблена комп'ютерна програма обробки параметрів хімічного зараження та розрахунку втрат серед працюючого персоналу та мешканців які можуть опинитися в зоні аварій об'єктів хімічної промисловості, або викиду в навколишнє середовище (ОР, СДОР). Проведений аналіз розрахунків без застосування комп'ютерної програми обробки параметрів хімічного зараження та з її використанням підтверджує про достовірність її розробки на базі програмного продукту Microsoft Visual Studio (Visual C#). Запропонована методика розрахунку та оцінки хімічної обстановки після аварій та руйнувань на об'єктах хімічної промисловості. Описане практичне застосування розробленої комп'ютерної програми, яка дає можливість фахівцям у сфері цивільного захисту (ЦЗ) більш швидше проводити розрахунки щодо визначення ступеню вертикальної стійкості повітря, глибини та площі розповсюдження хімічної хмари, часу досягнення до населеного пункту, втрат як працюючого персоналу так і населення, оперативніше приймати рішення як в мирний час так і в особливий період. Дані висновки стосовно проведених розрахунків та отриманих результатів при розв'язуванні задач з оцінки хімічної обстановки з використанням сучасних технологій.

**Ключові слова:** *вплив небезпечних речовин, відносна токсичність, ліквідація наслідків аварій, кількісна характеристика токсичності, ураження на хімічно небезпечних об'єктах.*

## 1. INTRODUCTION

In Ukraine, as in other industrial countries of the world, there are facilities where a large number of various chemicals, which are dangerous to the environment, toxic and harmful to human and animal health, are manufactured, recycled, disposed. Such substances are called HTS (highly toxic substances). Many of them are carried with transport, which in turn increases their risk during accidents. In addition, during a special period of state functioning, objects that store HTS may be deliberately destroyed (Bell *et al.*, 2017; Bourdrel *et al.*, 2017; Melnichuk *et al.*, 2020; Tyliczszak *et al.*, 2009; Talismanov *et al.*, 2018; Kosnik and Reif, 2019; Mo *et al.*, 2019; Krechetov *et al.*, 2018; Zavala *et al.*, 2020). In peacetime, in the event of accidents, catastrophes or other natural disasters, HTS can enter the environment and cause damage to humans, animals, plants, in

particular cause fatalities. In peacetime as well as in a special period to eliminate threats to life and health, civil protection is implemented through the implementation of localisation plans and the elimination of accidents or catastrophes. There are many different methods used to calculate the parameters of chemical contamination, which take into account the toxic properties of toxic substances (Steblyuk, 1998; Williams *et al.*, 2017; New Hampshire..., 2019; NTP. National Toxicology..., 2019).

Civil protection is one of the main priorities of the activity of the central state authorities, bodies of local self-government institutions and organisations throughout Ukraine. From the foregoing, it is clear that due consideration of the post-accident chemical environment at the facilities of the chemical industry needs to be given sufficient attention, in particular to study, investigate and implement both organisational and

technical measures (Manucci and Franchini, 2017).

Many well-known scientists were engaged in studying of PS and HTS, research and development of methods of chemical situation estimation at different times: V. N. Aleksandrov (Alexandrov and Emelyanov, 1990) classified the main types of poisonous substances, the nature and extent of their toxic action, V. G. Atamanyuk (Atamanyuk *et al.*, 1986) described the definition of the stability of poisonous substances, A. T. Altunin (1984) described the actions of the population in the conditions of infection with highly toxic substances, G. G. Migovich (2001) listed the general analytical formulas for determining the individual components of the chemical situation estimation, P. T. Egorov (Egorov *et al.*, 1977) characterised the chemical intelligence instruments, I. M. Mitsenko (Mitsenko and Mizentseva, 2004) disclosed the classification of toxic substances, A. P. Volkov (1988) highlighted the special treatment of objects after the influence of PS and HTS, M. I. Steblyuk (1998; 2006), V. I. Bukhtoyarov (1988), V. M. Shobotov (2006) proposed the calculation of the determination of the individual components of the chemical situation. The mentioned works describe the physicochemical and toxic properties of PS and HTS, give the general analytical formulas for determining the depth and area of chemical contamination, the calculations of determining the stability and time of an approach of the infected cloud from the emergency object to the settlement, but there are no algorithms of calculation starting from the initial data and ending with the projected loss of residents who will be affected by HTS. The writings of A. A. Zuikova (2006), A. V. Katkovsky (2015) consider increasing the effectiveness of decision-making in accidents with the release of chemically hazardous substances, pay attention to the use of computer technologies to solve environmental problems and industrial safety problems, draw attention to the use of information technology in the assessment of chemical environment after accidents on chemical facilities, however, the calculation using the software is not provided (Ring *et al.*, 2017; Casey *et al.*, 2018; Centers for Disease..., 2019; Wambaugh *et al.*, 2019).

A review and analysis of the literature in the Scopus database showed that, for example, there are works (Gervich, 2016; Jordan and Abdaal, 2013; Jordan *et al.*, 2009; Pashtetskiy *et al.*, 2020; Konyavsky and Ross, 2019; Wang and Wang, 2014) that make a comparative characterisation of socio-economic systems for better understanding

of the effects of industrial pollution on society; modern methods to support decision-making for ecological assessment of pollution in the mine territories and spatial modelling of contamination of reservoirs by processing industry have been considered; the ecological situation on water pollution after fire in chemical industry has been researched (US EPA (US Environmental..., 2018).

Currently, there are many programs for calculating chemical contamination parameters, such as ALOHA. The program is powerful, written in English. It is not adapted for the departments of the CP of Ukraine (Everything you need..., 2019; Ginsberg *et al.*, 2019; Yudaev *et al.*, 2019a; Yudaev *et al.*, 2019b; Zykova *et al.*, 2019; Rabinskiy and Tushavina, 2019). It is therefore understandable that the methodology for assessing the chemical environment should be investigated, studied, calculated and the results obtained – analysed. In order to promptly calculate the chemical situation, make timely decisions on protecting workers and residents who are affected by PS or HTS due to accidents at chemically hazardous sites, civil protection professionals need to have software that will speed up the calculation and enable them to take timely action on localisation and elimination of consequences of accidents at chemical industry facilities (Oltra *et al.*, 2017; Richmond-Bryant *et al.*, 2018; Jennifer, 2020).

The aim of the article – on the basis of the analysis of the existing methods of assessment of the chemical environment and the necessity to quickly respond to the consequences of accidents occurring at the facilities of the chemical industry, to develop an operational assessment of chemical contamination, to calculate the chemical situation without using software and with its use, to analyse the reliability of the results obtained.

#### Research objectives:

- 1) To analyse existing methods of calculating chemical contamination parameters.
- 2) To develop an algorithm for calculating the chemical post-accident assessment of a chemical facility (Figure 1).
- 3) To develop an operational assessment of chemical contamination.
- 4) To evaluate a chemical situation without the use of an operational assessment of chemical contamination and with its use, to analyse the reliability of results.
- 5) To analyse the results obtained using an operational assessment of chemical contamination.

## 2. MATERIALS AND METHODS

In order to determine the scale, nature, extent of exposure of hazardous substances to humans, animals, plants, foodstuffs, and the development of appropriate actions of the CP and the population before liquidation of chemical contamination and works on the site, chemical conditions are evaluated (Melnyk, 2013; Melnyk, 2014). The baseline data for assessing the chemical situation are:

- 1) the area and time of application of the HS or release into the environment of HTS;
- 2) type and amount of HS or HTS;
- 3) the degree of protection of humans, animals, food;
- 4) storage conditions (under pressure, without pressure) and the nature of hazardous chemicals entering the environment;
- 5) topographical conditions of the terrain, nature of development, presence of forest plantations on the way of spread of contaminated air. The configuration of the terrain, as well as all natural and artificial objects located on it (rivers, forests, shrubs, mountains, settlements, (closed terrain) affect the final result of the software calculation. This condition is taken into consideration upon entry of the initial data;
- 6) meteorological conditions: wind speed and direction in the surface layer, air and soil temperature, degree of vertical stability of air.

The degree of vertical stability of the air ground layer can be determined from the data of meteorological surveys. In addition, it can be more accurately determined by the wind speed at an altitude of 1 m and a temperature gradient (Equation 1) where  $t_{50}$  – air temperature at a height of 50 cm;  $t_{200}$  – air temperature at an altitude of 200 cm from the earth's surface. When the ratio of magnitudes  $\Delta t / v^2 \leq -0.1$  there will be inversion,  $-0.1 < \Delta t / v^2 < +0.1$  – isothermy, and  $\Delta t / v^2 \geq +0.1$  – convection. HSs are characterised by their toxicity (toxikon – poison). It is an important characteristic of HS that determines their ability to cause pathological changes in the body that lead to severe consequences or death. The quantitative characterisation of the toxicity of HS is determined by a dose (Vozza, 2017; Sarma *et al.*, 2018). The dose of a substance that causes a certain toxic effect is called the toxic dose (D). The toxic properties of HS are determined experimentally on different laboratory animals, so they are more

likely to use the concept of specific toxic dose – the dose attributed to the unit of live weight of the animal and expressed in milligrams per kilogram (mg/kg). Toxic doses (Alexandrov and Emelyanov, 1990) are divided into:

- 1) mortal;
- 2) incapacitating vital activity;
- 3) initial.

Toxic doses of HS of skin and resorption action are divided into:

- Lethal toxic dose  $LD$  (from Lat. letalis – lethal) – is the amount of HS that causes death upon penetration into the body with a certain probability, it is denoted respectively  $LD_{100}$  or  $LD_{50}$ , (100%, 50% of wounded).
- Toxic dose that incapacitates vital activity  $ID$  (from the English “incapacitate”) – is the amount of HS that infringe vital activity both temporally or lethally of a certain percentage of wounded when penetrating a body, it is denoted respectively  $ID_{100}$  or  $ID_{50}$ , (100%, 50 % of wounded).
- Initial toxic dose  $PD$  (from English “primary”) – the amount of PS that causes the initial signs of damage to an organism with a certain probability or the initial signs of damage in a certain percentage of humans and animals. Initial toxic doses are denoted  $PD_{100}$  or  $PD_{50}$ . (100%, 50% initial signs of a lesion).

It is more difficult to calculate toxic doses for PS that enters the human body as a vapour by inhalation. First of all, it is suggested that the inhalation toxic dose is directly proportional to the concentration of PS in the air,  $C$ , and the time of inhalation  $\tau$ . In addition, it is necessary to take into account the intensity of breathing  $V$ , which depends on physical activity and human condition. In a calm state, a person takes about 16 breaths per minute and absorbs 8-10 l/m of air on average. During medium exercise, the absorption of air increases to 20-30 l/m, and during heavy physical exertion is approximately 60 l/m. Thus, if a person weighing  $G$  (kg) inhales air with a concentration of PS  $C$  (mg/l) in it during  $\tau$  (min) with the intensity of breathing  $V$  (l/min), then the specific absorbed dose of PS (the amount of PS into the body) will be equal to Equation 2.

In (Alexandrov and Emelyanov, 1990), the German chemist F. Haber proposed to simplify this expression. He made the assumption that the relationship is constant for humans or a specific species of animals that are in the same conditions.

Divide both parts of the equation in this relation, he obtained the Equation 3.

F. Haber called  $C \cdot \tau$  toxicity coefficient and assumed it as a constant. Although this product is not a specific toxic dose, it does allow comparison of different PSs by inhalation toxicity. If, for example,  $C \cdot \tau$  for yperite is  $1.5 \text{ mg} \cdot \text{min/l}$  and for phosgene  $3.2 \text{ mg} \cdot \text{min/l}$ , it is clear that inhalation of yperite is about 2 times more toxic than phosgene. Notwithstanding many other factors that affect toxicity, the value  $C \cdot \tau$  is used to evaluate the inhalation toxicity of PS and is referred to as relative inhalation toxicity. For the characteristics of the lethal, life-threatening and primary toxicity of the PS, which affect the human body by inhalation in the form of steam or aerosol, use the same letters and indexes as with toxic doses of skin-resorptive action. They are denoted respectively  $LC\tau_{100}$  and  $LC\tau_{50}$ ,  $IC\tau_{100}$  and  $IC\tau_{50}$ ,  $PC\tau_{100}$  and  $PC\tau_{50}$ . The relative toxicity  $C \cdot \tau$  during inhalation depends on the physical exertion on the person. For people engaged in heavy physical labour, it will be much less than for people who are at rest. With increasing respiratory rate, the rate of action of the PSs increases. For example, for *GB* with pulmonary ventilation, the value is  $0.075 \text{ mg} \cdot \text{min/l}$  and  $0.025 \text{ mg} \cdot \text{min/l}$ , respectively, and if for phosgene the product  $C \cdot \tau$   $3.2 \text{ mg} \cdot \text{min/l}$  at respiratory rate is medium lethal, then for pulmonary ventilation  $40 \text{ l/min}$  is absolutely lethal. Table 1 shows the toxicological characteristics of HPs.

Tabular values of skin resorptive PS are valid only for infinitely large exposure, that is, for cases where PSs, that hit the skin surface, are not removed or degassed. In fact, for the manifestation of one or another toxic effect on the surface of the skin, there must be a greater amount of poison than the toxicity of toxic substances given in the table. This amount and the time during which PS is on the surface of the skin during absorption, in addition to toxicity, is largely due to the rate of absorption of the PS through the skin. Thus, according to US specialists, a substance *VX* characterised by a skin-resorptive toxic dose  $LD_{50}$   $6\text{--}7 \text{ mg}$  per humans will enter the human body if the droplet-liquid *VX* amounted at  $200 \text{ mg}$  is on the surface of the skin for 1 hour, or approximately  $10 \text{ mg}$  – for 8 hours. Due to the protective properties of the clothing, this amount is increased, and in the summer for 8 hours exposure will be approximately  $95 \text{ mg}$ .

It should be noted that the table values of the constant  $C \cdot \tau$  are valid for short exposures,

which differ significantly for different poisonous substances depending on their physical, physicochemical and chemical properties. For *AC* this value is valid if  $\tau$  – several minutes, and for *CG* – within one hour. The extent of damage caused by accidents at chemically hazardous sites depends first of all on the number of PSs, meteorological and topographic conditions of the area, the type of storage of HTSs (under pressure, without pressure). From the above it can be concluded: protective measures and, above all, the forecasting, detection and periodic monitoring of the chemical situation, alerting the personnel of the enterprise, the population and the CA forces, should be carried out with extremely high speed.

To create an operational assessment of chemical contamination and enable timely decision-making on taking measures to localise and eliminate the consequences of accidents at chemical industry facilities, it is necessary to develop an algorithm for civil protection professionals to evaluate chemical contamination parameters. It must start from the moment of receipt of the initial data on an object at which an accident occurred, its location, settlement, if any, the number of residents who live in it, ending with calculations of the consequences of chemical contamination, possible loss of working staff at this facility, a population that is projected to fall into the zone of chemical contamination.

- 1) Develop an algorithm for calculating the chemical post-accident assessment of a chemical facility (Figure 1).
- 2) Develop an operational assessment of chemical contamination.
  - a) Create a new project “Windows Form Application”.
  - b) Add software elements.
  - c) Write the program code.
  - d) Add reference material.
  - e) Run the program and enter the corresponding output data.
  - f) Calculate the problem.
  - g) Obtain the results of the calculation.

The program works in accordance with the algorithm provided in (Figure 1). Let us enter the source data. In accordance with the input data, the software determines the degree of vertical stability of the air (inversion, convection, isothermy). Considering the topographic conditions of the area (source data), the Depth (D) and the area (S) of chemical contamination are calculated (Figure 1).

The next step is the time it takes to reach and the time it takes to affect people with toxic substances. Further, the software calculates population losses by degrees of severity, taking into consideration the availability of personal protective gear. The software interface is as follows (Figure 2).

Table 2 provides statistics on past accidents. Table 2 was developed with the use of software modelling of data.

### 3. RESULTS AND DISCUSSION:

The study was conducted on the following input data (Melnyk, 2014):

1. An emergency object: Kind of HTS – chlorine; Quantity of HTS – 10 t; Type of container – unbuttoned; Number of employees – 600 people; Gas supply is 70%.

2. Settlement: Distance to the village R-3 km; Number of inhabitants 1000 persons; Gas mask security – 90%; Terrain – open; Meteorological conditions –  $V_w = 2$  m/s,  $\Delta t^\circ\text{C} = 70.1$

Calculation sequence:

1. Determine the degree of vertical stability of the air: Wind velocity  $V_w = 2$  m/s and  $\Delta t^\circ\text{C} = 0,1$  – isothermy.

2. Determine the depth of CCZ:  $D = 7$  km. Take into account the correction coefficient of wind speed:  $D = 7 \text{ km} \cdot 0.7 = 4.9 \text{ km}$ ;  $D = 4.9 \text{ km}$ .

3. Determine the width of CCZ:  $W = 0.15 \cdot G$  – isothermy.  $W = 0.15 \cdot 4.9 \text{ km} = 0.74 \text{ km}$ .  $W = 0.74 \text{ km}$ .

4. Determine the area of CCZ:  $S = 1/2 \cdot G \cdot W$ .  $S = 1/2 \cdot 4.9 \text{ km} \cdot 0.74 \text{ km} = 1.8 \text{ km}^2$ ;  $S = 1.8 \text{ km}^2$

5. Map the predicted CCZ (Figure 1).

6. Determine the  $t_{\text{reach}}$  of contaminated air to the locality:  $t_{\text{reach}} = 3000 \text{ m} / (3 \text{ m/s} \cdot 60) = 16.66$  minutes.

7. Determine the HTS  $t_{\text{affection}}$ : affection =  $1.3 \text{ h} \cdot 0.7 = 0.91 \text{ h}$ .

8. Calculate the possible losses of employees:

$600 \cdot 18\%/100\% = 108$  persons – total losses (t.l.);

$108 \cdot 25\%/100\% = 27$  persons with lesions of mild degree (m.d.);

$108 \cdot 40\%/100\% = 43$  persons of moderate and severe degree (m.s.d);

$108 \cdot 35\%/100\% = 38$  persons – fatalities (f.).

9. Calculate the possible population loss:

$1000 \cdot 9\%/100\% = 90$  persons t.l.;

$108 \cdot 25\%/100\% = 23$  persons m.s.d.;

$108 \cdot 40\%/100\% = 36$  persons m.d.;

$108 \cdot 35\%/100\% = 31$  persons f.

The results of the calculation are shown in Table 3.

### 4. CONCLUSIONS:

Comparative analysis of the results obtained from the solution of the problem of chemical post-accident assessment at a chemical industry facility conducted in two ways: without using an operational assessment of chemical contamination and with its use testify to the correctness of the developed an operational assessment of chemical contamination software product in accordance with the proposed methodology. The novelty of the obtained results is that a methodology for the assessment of the chemical situation after accidents at the chemical industry facilities is improved and an operational assessment of the parameters of chemical contamination is developed.

The existing methods of calculation of chemical contamination parameters were analysed. The algorithm of calculation of chemical contamination parameters was given. An operational assessment of chemical contamination using Microsoft Visual Studio (Visual C#) was developed. The software can be downloaded from <https://visualstudio.microsoft.com/ru/vs/express/> for calculation and estimation of a chemical situation after accidents and destruction at chemical industry facilities. The chemical situation without using an operational assessment of chemical contamination and with its use was estimated, the reliability of the obtained results was analysed. The developed operational assessment of chemical contamination will enable the specialists of city and district departments of civil protection and defence-mobilisation work to make calculations on chemical situation more promptly, to take timely measures of protection of workers, population and territories that will be under the influence of HS and HTS.

## RESUMO

Nos últimos anos, muita atenção tem sido dada ao uso de fontes geotérmicas na pesca. As perspectivas para esta área são enormes, pois abrem oportunidades para o gerenciamento de processos de criação de peixes, independentemente das condições climáticas. O principal objetivo do estudo foi uma análise abrangente dos processos tecnológicos de piscicultura. Uma das reservas promissoras para o aumento da produção de peixes é o uso racional de resíduos comerciais de água quente e fontes geotérmicas. O trabalho de pesquisa foi realizado em 2019 com base na fazenda TOO Tengri Fish, localizada a 270 quilômetros da cidade de Almaty. Os materiais foram coletados e processados de acordo com os métodos geralmente aceitos em ictiologia e piscicultura e subsequentemente analisados por meio de computador pessoal. Com base nos resultados do estudo, foram determinadas as primárias tecnológicas da criação de tilápia em SRA (sistema de recirculação da aquicultura) utilizando águas geotérmicas. Durante o estudo, foi realizado um trabalho para otimizar o regime hidroquímico. Os principais indicadores de criação de peixes e indicadores biológicos de crescimento e desenvolvimento de peixes da tilápia foram estabelecidos. Foi determinada a densidade ideal da tilápia em sistemas de recirculação da aquicultura usando água geotérmica e a temperatura em que a tilápia tem um ganho médio diário mais alto. A novidade do trabalho: um estudo abrangente da biologia e a adaptação de uma nova unidade de piscicultura industrial de tilápia e peixe-gato, realizado fora da área natural e que determinou a possibilidade de adaptar tilápia e peixe-gato a fatores extremos do ambiente aquático.

**Palavras-chave:** *fonte geotérmica, desgaseificação, caviar, larva, hidroquímica.*

## ABSTRACT

Over recent years much attention has been paid to the fishery use of geothermal sources. The prospects for this area are enormous, as it opens up possibilities for managing fish-breeding processes, regardless of climatic conditions. The main objective of the research was a comprehensive study of the technological processes of growing. One of the promising reserves for increasing fish production is the rational fishery use of waste warm water and geothermal sources. Research work was carried out in 2019 based on the farm of "Tengri Fish" LLP, which is located 270 kilometers from Almaty. The collection and processing of materials were carried out according to generally accepted methods in ichthyology and fish farming, followed by their analysis on a PC. Based on the results of the research, technological primaries of growing tilapia in a RAS (Recirculating Aquaculture System) using geothermal waters were determined. During the research, work was carried out to optimize the hydrochemical regime. The main fish breeding and biological indicators for the growth and development of tilapia were established. The optimal stocking density of tilapias in recirculating aquaculture systems using geothermal waters and the temperature when tilapias have a higher average daily weight gain were found. The novelty of the research: a complex study of biology and adaptation of a new object of industrial fish farming of tilapia and clarium catfish has been carried out outside the range and determined the adaptation possibilities of tilapia and clarium catfish to extreme factors of the aquatic environment.

## АННОТАЦИЯ

В последние годы большое внимание уделяется использованию геотермальных источников в рыбном хозяйстве. Перспективы этой области огромны, так как она открывает возможности для управления процессами разведения рыбы, независимо от климатических условий. Основной целью исследования было комплексное изучение технологических процессов выращивания. Одним из перспективных резервов для увеличения производства рыбы является рациональное использование промысловых отходов теплой воды и геотермальных источников. Исследовательские работы проводились в 2019 году на базе фермы ТОО «Tengri Fish», расположенной в 270 километрах от Алматы. Сбор и обработка материалов проводились в соответствии с общепринятыми методами в ихтиологии и рыбоводстве с последующим их анализом на ПК. По результатам исследования определены технологические праймериз выращивания тилапии в РСА (рециркуляционной системе аквакультуры) с использованием геотермальных вод. В ходе исследования проводились работы по оптимизации гидрохимического режима. Установлены основные рыбоводные и биологические показатели роста и развития тилапии. Найдена оптимальная плотность посадки тилапии в рециркуляционных системах аквакультуры с использованием геотермальных вод и температура, при которой у тилапии наблюдается более высокий среднесуточный прирост веса. Новизна исследования: комплексное изучение биологии и адаптация нового объекта промышленного рыбоводства тилапии и клариумного сома, проведенного за пределами ареала, и определившего возможности адаптации тилапии и клариумного сома к экстремальным факторам водной среды.

**Ключевые слова:** геотермальный источник, дегазация, икра, личинка, гидрохимия.

## 1. INTRODUCTION

Over the past decades, aquaculture has become one of the fastest-growing areas of food production and plays an increasingly important role in the economic development of many countries. In terms of development, aquaculture is ahead of fish caught in the oceans and seas and today provides more than 40% of total fish production (Mamontov, 2000). One of the promising reserves for increasing fish production is the rational fishery use of waste warm water and geothermal sources. Over recent years, in our country and abroad, much attention has been paid to the fishery use of geothermal sources (Gurkina *et al.*, 2019; Lefers *et al.*, 2020). The prospects for this area are enormous, as it opens up possibilities for managing fish-breeding processes, regardless of climatic conditions (Budiasa *et al.*, 2018; Leite *et al.*, 2018).

A promising direction in fish farming is the use of not only the potential of inland water bodies but also the rational use of waste warm water and geothermal sources. Geothermal sources located on the territory of the Republic of Kazakhstan are one of the water areas where the cultivation and cultivation of new aquaculture facilities with a high growth rate and valuable taste qualities are quite promising (Beisembayeva *et al.*, 2017; Syzdykov *et al.*, 2019).

Geothermal waters in different regions of

the country and at different levels of occurrence can vary significantly. The temperature of such waters also varies from 30-40 to 80-90 °C and higher. A common characteristic feature of geothermal waters can be considered the absence of a minimum amount of dissolved oxygen, high content of carbon dioxide, and mineral salts. However, in the process of filling the ponds and their operation, the chemical composition of the water may change. In particular, it is saturated with oxygen, and the carbon dioxide content is reduced. In determining the possibility of using geothermal waters for fish farming, in each specific case, their careful chemical analysis is necessary (Tetdoyev, 2009; Tosun, 2017).

The area of application of geothermal sources in the national economy is expanding more and more and requires economic and rational use, including in fish farming (Tetdoyev, 2009; Tetdoyev and Pliyev, 2009). The chemical composition of the new, previously unknown aquatic environment, will allow establishing the degree of tolerance, adaptive plasticity, as well as their growth and development potential at different stages of cultivation when breeding fish farming objects (Tetdoyev, 2009; Tetdoyev and Pliyev, 2009).

Geothermal waters in different regions and at different levels of occurrence can vary significantly. The composition of geothermal waters is characterized by a large amplitude of

fluctuation both in chemical composition and in the number of salts and gases dissolved in it. A common characteristic feature of geothermal waters can be considered the absence or minimum amount of dissolved oxygen, high content of carbon dioxide, and minerals. However, in the process of filling the ponds and their operation, the chemical composition of the water may change. In particular, it is saturated with oxygen, and the carbon dioxide content is reduced (Boronetskaya, 1993; Mamontov, 2000; Tetdoyev, 2009; Bolotov *et al.*, 2016).

Scientists of Russia have experience in growing traditional fish farming objects (carp, wild carp), as well as new aquaculture objects (tilapia). Research on the cultivation of tilapia in ponds using geothermal water was carried out based on the fish breeding department of the Mostovskaya greenhouse complex in the Krasnodar Territory (Mamontov, 2000; Tetdoyev, 2009). Studies have shown that the geothermal water of the Mostovskoye field belongs to sulfate-sodium waters, has a temperature of 75-800 °C. Mineralization of water is low (1-1.5 g/l). Geothermal water was pre-mixed with river water and then fed into fish ponds. The ratio of geothermal and river water varied depending on the season of the year. The temperature in the ponds was also regulated due to the intensity of water exchange (Tetdoyev, 2009). Russian scientists conducted experiments on growing carp using geothermal, weakly mineralized, carbonate-chloride-sodium water from deep wells with total salinity in hatcheries from 1.9 to 3.6 g/l, and in commercial fish plots up to 12.2 g/l (Pevnev, 2000; Korentovich *et al.*, 2017).

The new economic conditions in Kazakhstan over the past decade (2010-2020) put the fisheries industry in a rather difficult position, and therefore, the per capita consumption of fish products for this period reached only 4 kg, that is, 2.5 times less than the following consumption rate (14 kg per capita), which reduced the usefulness of protein nutrition. The principal, decisive factor for solving this issue will be, first of all, the development of aquaculture in the Republic of Kazakhstan, using available water resources and the introduction of new aquaculture facilities – fish with an intensive growth and development rate, crustaceans, mollusks, aquatic plants and other aquatic organisms (Master plan of commercial..., 2011).

Growing fish in industrial fish farms has several advantages over pond farming. No more than 0.01 m<sup>2</sup> of land and 0.005 m<sup>3</sup> of water are spent on the production of 1 kg of products in

industrial fish farming, which is two orders of magnitude less than in pond fish farming. At the same time, a high yield of fish products is achieved – 100 kg or more from 1 m<sup>2</sup> of cage and pool area. One of the real ways to increase the economic efficiency of industrial fish farming is to grow more valuable fish species that have a reasonably high growth and development rate, unpretentiousness to the habitat and food, high fecundity, and high taste (Pruszyński and Pistelok, 1999; Shelton, 2002; Rothbard and Peretz, 2002; Zdanovich and Pushkar, 2007; Tetdoyev and Boronetskaya, 2008).

The main objective of the research is a comprehensive study of the technological processes of growing Nile tilapia at geothermal sources. In order to achieve the objectives, the following tasks had to be accomplished:

- to study the features of the hydrochemical regime of geothermal sources (thermal regime, gas and salt composition of water);

- study of the influence of technological factors (planting density, feeding level) on the growth and development of tilapia when kept in a water storage system using geothermal water.

The novelty of the research: a complex study of biology and adaptation of a new object of industrial fish farming of tilapia and clari catfish has been carried out outside the range and determined the adaptation possibilities of tilapia and clari catfish to extreme factors of the aquatic environment: lack of oxygen dissolved in water, high and low concentration of ions (pH), high concentration of minerals (Grande Burgos *et al.*, 2018; Billah *et al.*, 2020; Mansano *et al.*, 2020).

## 2. MATERIALS AND METHODS

Research work was carried out in 2019 based on the farm of “Tengri fish” LLP, which is located 270 kilometers from Almaty, near the village of Chunzha, on a plot of 15 hectares. This farm has two deep, self-flowing, artesian, geothermal wells. Previously, it was conducted hydrochemical studies of geothermal waters in order to determine the hydrochemical regime of water bodies for the subsequent planting of aquaculture objects in them – tilapia and Clari (African) catfish.

Aquaculture objects were grown at a planting density of 50-150 kg/m<sup>3</sup> for African catfish and 30-50 kg/m<sup>3</sup> for tilapia. Feeding was carried out with specialized Aller aqua aquaculture feeds

containing 45% protein, 15% fat, and 22% carbohydrate. The daily diet ranged from 10% for juveniles to 3% for marketable fish. Each month, fish were sorted to reduce planting density and uniform fish growth. The OxyGuard Handy Polaris Thermo Oximeter was used for daily monitoring of oxygen in the water. Water samples were taken to describe the complex hydrochemical regime in fish hatcheries. The studies were carried out in an accredited hydrochemical laboratory of the Scientific Analytical Center LLP.

To characterize the hydrochemical regime in fish hatcheries, water samples were taken. The studies were carried out according to standard methods. The control of the hydrochemical regime was carried out according to the following leading indicators (parameters) – oxygen content ( $O_2$ ), carbon dioxide ( $CO_2$ ), pH – medium, water temperature ( $t\text{ }^{\circ}C$ ), as well as the content of nitrates ( $NO_3$ ) and nitrites ( $NO_2$ ) (Semyonov, 1977; Yudin, 1980). For ichthyologic studies, generally accepted research methods used in fish farming were used. The ichthyologic analysis includes the determination of linear dimensions, weight, fatness (Pravdin, 1966). The growth rate of the studied fish was carried out according to accepted methods (Chugunova, 1959; Privezentsev, 1991). Ichthyological studies were carried out every 7 days in order to determine the growth rate and calculate the daily diet.

### 3. RESULTS AND DISCUSSION:

#### 3.1. The Features of the Hydrochemical Regime of Geothermal Sources

Geothermal waters in different regions of the country and at different levels of occurrence vary significantly. The composition of geothermal waters is characterized by a large amplitude of fluctuation both in chemical composition and in the number of salts and gases dissolved in it. A characteristic feature of geothermal sources can be considered the absence or minimum content of dissolved oxygen with a high content of carbon dioxide and minerals (Boronetskaya, 1993; Pevnev, 2000).

Studies on the cultivation of tilapia using geothermal waters were carried out based on the fish farm of "Tengry fish" LLP. This farm is located in the Almaty region, Uygur district, the village of Chunzha, for fish growing was used as a system of closed water supply systems with geothermal water. As this study shows, as well as data from foreign scientists (Boronetskaya, 1993; Pruszyński and Pistelok, 1999; Pevnev, 2000; Tetdoyev, 2009; Bolotov *et al.*, 2016; Korentovich

*et al.*, 2017), the minimum salient oxygen content at high content of carbon dioxide and mineral salts can be considered a common characteristic feature of geothermal sources. Accordingly, in the waters of geothermal sources used in this study, the hydrochemical regime corresponded to the above data. Preliminary studies of water from geothermal sources indicate that the maximum permissible concentrations of carbon dioxide (80.1 mg/l) and total nitrogen (2.86 mg/l) are exceeded. Table 1 shows the hydrochemical parameters of water of geothermal sources, and in Figure 1, the proportion of chemical components present in the geothermal source.

The negative effect of a high concentration of carbon dioxide on the vital activity of fish is that fish, being in a depressed state, use oxygen dissolved in water worse. Moreover, not only the absolute content of oxygen and carbon dioxide (carbon dioxide) in the water is essential, but their ratio. For carp, for example, the ratio of  $O_2$  and  $CO_2$  approaching 0.02 is dangerous. With a low oxygen content and an unfavorable ratio of  $O_2$  and  $CO_2$ , fish use feed much worse. The critical carbon dioxide concentration varies for different fish species.

The high content of carbon dioxide leads to a decrease in pH, as a result of which prerequisites are created for limiting the transfer of blood oxygen in the gills. As a result, signs of asphyxia in fish develop. Nitrogen is less toxic to fish. However, fodder and vital products of fish continuously get into the fish's artificial keeping water, and in the process of their decomposition, a large amount of phosphorus and nitrogen is formed in the form of ammonia. This leads to the uncontrolled growth of algae and causes intoxication of the fish organism; chronic gill lesions occur. According to hydrochemical analyzes, the concentration of iron did not exceed the MPC. However, it should be noted that iron in the water of geothermal sources is presented as divalent, which, in turn, is toxic to caviar and juvenile fish.

In order to regulate and optimize the hydrochemical regime of the waters of the geothermal spring, it is necessary to reduce the carbon dioxide content. The removal of carbon dioxide in geothermal springs was carried out by the method of degassing – by aeration of water or by stripping. Aeration is carried out by forcing air into water. With this degassing method, the turbulent contact of air bubbles and water removes gases. In this research, a more effective degassing method is stripping. In a drip filter system, gases are stripped by physical contact

between water and a plastic aggregate (bio blocks) stacked in a column. The stripping process will remove carbon dioxide and nitrogen from the water, and the aeration well will allow ferrous iron to become ferric with subsequent conversion to iron oxide, which precipitates (Figure 2). As a result of regulation by the method of degassing the hydrochemical regime in the pools, it was found that the water indicators practically corresponded to the normative indicators (Table 2). As shown in Table 2, the effective operation of the degassing unit is reflected in a decrease in carbon dioxide concentration by 20 times from the initial one and increases the concentration of dissolved oxygen by two times.

As reflected in Figure 3, when using the degassing method, the level of dissolved oxygen in closed water supply plants almost reached the maximum level and averaged 6.27 mg/dm<sup>3</sup>. This was seen in the behavioral response of fish (tilapia). At the initial stage of the experiment, when using water from geothermal springs, after degassing, the fish behaved relatively passively, inactive, sluggishly took food, and for the most part, they were at the surface of the water. Subsequently, as the concentration of dissolved oxygen increased, the activities of the fish increased, willingly and actively took food and were dispersed over the entire basin. The highest activity was observed during the periods of July-August. The method of degassing effectively reduced the concentration of carbon dioxide (Figure 4). Figure 4 shows the dynamics of decreasing carbon dioxide concentration in the recirculating aquaculture system with the content of tilapias up to 71%. In this study, the pH dependence on carbon dioxide concentration is traced. According to V. V. Tetdoyev (2009) research, low pH is "favorable" for the presence of free carbon dioxide. When pH increases to 8, the balance shifts towards the formation of bicarbonate (HCO<sub>3</sub>), resulting in a reduction in free carbon dioxide. This study notes a gradual increase in the pH value (Figure 5). As reflected in Figure 5, the pH of water in basins with tilapias was predominantly of a weakly alkaline environment.

Figure 6 reflects the general dependence of pH on carbon dioxide using geothermal waters while keeping tilapia in the recirculating aquaculture system. The inverse dependence of pH on the content of carbon dioxide becomes evident after drawing the trend lines: the higher the concentration of carbon is, the lower is the pH of the medium. A similar tendency can be observed for "the content of carbon dioxide – pH of the

medium" pair. In order to confirm that, the correlation ratio in these pairs of features was calculated. In the pair "carbon dioxide – concentration", it was  $r = -0.448$ , and in the pair "pH – ionic medium"  $r = -0.04$ . To determine the effect of the temperature on tilapia growth, in the process of growing the mint here circulating aquaculture system using geothermal waters, experiments with temperature regimes from 25 to 33 °C was conducted. The results of the experiment are represented in Table 3. The results of the experiment proved the advantages in the growth of tilapias, which had been kept at the temperatures of 29 °C and 30 °C. The tilapias kept in these temperature regimes have higher average daily weight gain rates, which indicates the high activity of fish and, consequently, feed digestion.

### **3.2. Influence of Technological Factors on Tilapia Growth and Development at Content in Recirculating Aquaculture System Using Geothermal Waters**

The main task of the conducted research was to develop technological processes of tilapia rearing and cultivation in a recirculating aquaculture system with geothermal water supply. In the course of the research, tilapias (females) were evaluated and then divided into three groups – with stocking densities of 100, 200, and 300 pcs/m<sup>3</sup>, respectively. Live weight and body indices were used as the main criteria for a comprehensive evaluation of the investigated fish population. The evaluation was also carried out in terms of secondary sexual characteristics.

Reproductive qualities were checked based on the results of two successive spawnings. The first spawning was carried out with fish kept at a water temperature of 27-29 °C in the basins. As a result of observations, it was found that the females matured 35-40 days after spawning. The results of tilapia growing at different stocking densities are presented in Table 4. The results of the studies have shown (Figures 7, 8) that tilapias grown under conditions of high stocking density are inferior in growth rate, the highest growth rate is observed in the basins with the lowest planting density.

As it can be seen in Figures 7-8, the growth rate is directly proportional to the density of fish stocking in the basins, the optimal density for growing tilapia in the basins using recirculating aquaculture system with geothermal water supply is 100 pcs/m<sup>3</sup>. At the same time, with a denser stocking, tilapia size and weight indices are close to commercial fish, and only a decrease in working fecundity and relative fecundity is noted (Table 4).

In order to determine the reproductive quality of tilapias grown under conditions of keeping in recirculating aquaculture system basins with geothermal water supply, studies were conducted (Table 5). Productive qualities of tilapias were identified during the periods of two spawnings. Assessment of tilapias productive and reproductive qualities at a specific stocking density and spawning order revealed certain differences.

The results of the performed research showed that tilapias grown in recirculating aquaculture systems using geothermal waters at a high density of stocking reflect the tendency to depend on the density level. The measurements taken at optimal stocking of tilapias with a density equal to 100 pcs/m<sup>3</sup> show that the fish had high fecundity rate rates compared to tilapias grown at stocking densities of 200 to 300 pcs/m<sup>3</sup>. When assessing the efficiency of cultivation, not only the gross yield of products was taken into account, but also their commercial and nutritional qualities, as well as the efficiency of use of the given feeds.

Expectedly, the highest growth rate was observed in the basin with the lowest stocking density (average weight 300 g). 98% of tilapia, which had been kept at a stocking density of 100 pcs/m<sup>3</sup>, was esteemed as a standard product. In the third variant of growing, with a stocking density of 300 pcs/m<sup>3</sup>, the average fish weight was about 196 g, with only 14% of the yield of standard production (above 250 g). Feed consumption is not more than 2.5 kg/kg weight gain.

Aquaculture is one of the fastest-growing areas of food production in the world market. Tilapia is one of the top contributors to the increase in aquaculture production. Tilapias are grown in more than 120 countries. The largest tilapia producers are China – 51% (897.3 thousand tons), Southeast Asian countries (Philippines, Indonesia, Thailand), Mexico, and Egypt. In Europe, tilapias are cultivated in Germany, France, Belgium, Czech Republic, Bulgaria, and some other countries.

Such a rapid spread of tilapia in world aquaculture and a significant increase in its production are associated with several valuable biological characteristics and economic benefits that are peculiar to these fish. (Boronetskaya, 1993; Pevnev, 2000; Shelton, 2002; Rothbard and Peretz, 2002; Tetdoyev, 2009; Tetdoyev and Pliyev, 2009; Boronetskaya and Privezentsev, 2011; Boronetskaya, 2012).

Tilapias are also of great interest in fish farming in Kazakhstan. In our country, the first studies related to the study of tilapia as a possible

object of domestic aquaculture have been launched quite recently. As researches have shown, the natural and climatic conditions of our country allow cultivating it in the southern regions of the republic. Also, a promising production base for tilapias is industrial fish farms that use natural and technical warm waters, including the use of geothermal sources.

The necessary condition ensuring the realization of the high genetic potential of tilapias in the knowledge of their requirements to the main water parameters – temperature, dissolved oxygen in the water and other water quality parameters, their adaptation capabilities. In this regard, the research tasks included, on the one hand, the study of the peculiarities of the hydrochemical regime of geothermal sources (thermal regime, gas and salt composition of water, etc.), and on the other hand – the study of the influence of technological factors (density of stocking, feeding level) on the growth and development of tilapia in the recirculating aquaculture system using geothermal water.

The work was carried out based on the fish farm of “Tengry fish” LLP. Several studies related to the influence of individual environmental factors were carried out in the conditions of the Research Center “Fish Industry”. When studying the technology of tilapia growing in recirculating aquaculture systems using geothermal waters, great attention was paid to studying their temperature regime. Temperature is one of the leading environmental factors determining the possibility and effectiveness of tilapia cultivation. The temperature regime in basins with geothermal water supply is practically in a controlled mode. The experience of cultivation of tilapias in conditions of keeping in ponds with geothermal water supply created essential problems in the winter period due to temperature decrease to 10-15 °C (Tetdoyev, 2009). Studies have shown that the closed water supply system provides reliable control of water quality and allows year-round reproduction and cultivation of fish.

One important indicator of water quality is the oxygen regime. Studies on tilapia growing in conditions of closed water supply using geothermal waters indicate that the oxygen regime was quite favorable for tilapia breeding. Assessing the environmental conditions for growing tilapias in conditions of closed water supply using geothermal waters, it can be concluded that they meet the requirements for tilapias. The ability to regulate several water quality indicators, in particular through degassing, will create the conditions to ensure the realization of highly

productive and reproductive qualities of these fish species.

Much attention was paid to the study of tilapia growth and development in the conditions of a recirculating aquaculture system using geothermal waters. In the course of the research, the reactions of tilapias to the technology of content (density of stocking) and, accordingly, its impact on growth and development and reproductive qualities were determined. Performed researches have shown high tolerance of tilapias to influence of adverse factors of environment, extensive adaptive possibilities and high productive qualities that confirms the possibility of cultivation of new object of aquaculture in Republic of Kazakhstan in the conditions of domestic industrial fish farms.

#### 4. CONCLUSIONS:

1. To regulate and stabilize the hydrochemical regime of geothermal sources, degasation was carried out, as a result of which the level of dissolved oxygen reached an average of 6.27 mg/dm<sup>3</sup>; pH 7.56; concentration of carbon dioxide to 2.11 mg/dm<sup>3</sup>.

2. As a result of growing tilapias at different stocking densities, it was found that the optimal stocking density of tilapias in recirculating aquaculture systems using geothermal waters is 100 and 200 pcs/m<sup>3</sup>. At the given density of stocking, higher indicators of growth rate are observed – absolute weight gain was 1603.1 g and 1357.1 g, respectively, in comparison with a stocking density of 300 pcs/m<sup>3</sup>, where absolute weight gain was 1214.2 g.

3. It has been found that reproductive qualities of tilapias grown in recirculating aquaculture system using geothermal waters at planting density from 100 to 200 pcs/m<sup>3</sup> are also higher in all parameters than those kept at planting density of 300 pcs/m<sup>3</sup>, concerning both the weight of producers and such indicators as fecundity, the mass of reproductive products, yield of larvae.

4. It has been found that at the temperature, 29-30 °C tilapias have a higher average daily weight gain and, accordingly, more efficient use of feeds.

#### 5. ACKNOWLEDGMENTS:

For successful research, we would like to express special gratitude to the Ministry of Education and Science of the Republic of Kazakhstan for the grant financing of the scientific

project on “Development of technology of cultivation of new aquaculture facilities on geothermal sources” (individual registration number No. AP05135409), “Tengry Fish” LLP for providing the base for research work.

Also, the work would be impossible without the participation of scientific, administrative, and technical personnel of Research Center “Fish economy”, at the Department of Hunting and Fisheries of S. Seifullin Kazakh Agro Technical University.

## RESUMO

A análise de Onduleta ou ondaleta (em inglês: *wavelet*) desempenha um papel de destaque em vários campos das disciplinas científicas. Particularmente, as wavelets são usadas com muito sucesso na análise de sinais para representação e segmentação de formas de onda, análise de frequência-tempo e algoritmos rápidos nas equações de propagação e reação. Esta pesquisa teve como objetivo orientar os pesquisadores a usar Cos e Sin (CAS) para aproximar a solução do sistema de equações diferenciais parciais. Este método foi aplicado com sucesso para resolver um sistema acoplado de sistemas não-lineares de difusão de reação onde foi demonstrado que o método de wavelets CAS é bastante capaz e adequado para encontrar soluções exatas uma vez que a consistência do método oferece uma aplicabilidade mais ampla onde a ideia principal é transformar equações diferenciais parciais não lineares complexas em sistemas de equações algébricas, fáceis de manusear e encontrar uma solução numérica para elas. Ao comparar as soluções numéricas dos métodos de elementos finitos CAS e Galerkin, a solução de sistemas não-lineares de difusão de reação usando as wavelets do CAS para todos os valores de  $x$  é precisa, confiável, robusta, promissora e chega rapidamente à solução exata. Quando os parâmetros  $\varepsilon_1$  e  $\varepsilon_2$  estão crescendo e com  $L$  diminuindo, o método CAS converge rapidamente para soluções em estado estacionário (quanto menos  $L$ , mais precisa é a solução). Ele está convergindo para soluções de estado estacionário mais rapidamente e perde etapas ao longo do tempo. Além disso, os resultados também mostram que a solução das wavelets CAS é mais confiável e mais rápida em comparação com os elementos finitos de Galerkin (G.F.E).

**Palavras-chave:** Sistema acoplado não-linear PDE, método de elementos finitos de Galerkin (G.F.E), solução numérica, wavelets Haar.

## ABSTRACT

Wavelet analysis plays a prominent role in various fields of scientific disciplines. Mainly, wavelets are very successfully used in signal analysis for waveform representation and segmentation, time-frequency analysis, and fast algorithms in the propagation equations and reaction. This research aimed to guide researchers to use Cos and Sin (CAS) to approximate the solution of the partial differential equation system. This method has been successfully applied to solve a coupled system of nonlinear Reaction-diffusion systems. It has been shown CAS wavelet method is quite capable and suited for finding exact solutions once the consistency of the method gives wider applicability where the main idea is to transform complex nonlinear partial differential equations into algebraic equation systems, which are easy to handle and find a numerical solution for them. By comparing the numerical solutions of the CAS and Galerkin finite elements methods, the answer of nonlinear Reaction-diffusion systems using the CAS wavelets for all  $\hat{t}$  and  $x$  values is accurate, reliable, robust, promising, and quickly arrives at the exact solution. When parameters  $\varepsilon_1$  and  $\varepsilon_2$  are growing and with  $L$  decreasing, then the CAS method converges to steady-state solutions quickly (the less  $L$ , the more accurate the solution). It is converging towards steady-state solutions faster than and loses steps over time. Moreover, the results also show that the solution of the CAS wavelets is more reliable and faster compared to the Galerkin finite elements (G.F.E).

**Keywords:** Coupled of nonlinear PDE system, Galerkin finite elements method (G.F.E), Numerical solution, Haar wavelets.

## 1. INTRODUCTION:

"Reaction-diffusion systems lead to the formation of tissue based on process simulations and nonlinear interactions, which were proposed as a model for the formation of a biological pattern. Alan Turing (1952) proposed the first chemical mechanism for calculating pattern formation in biological morphology, assuming tissue formation and chemical reaction and the amount of rate that depends on their concentration. These mechanisms are called reaction and diffusion systems" (Turing, 1952; Lepik, 2007; Qasim and Salim, 2019).

Wavelet analysis plays a prominent role in several areas of mathematics. The wavelets are utilized in the solution of all types of equations. These wavelets possess many remarkable properties. They studied intensively, and their connections with different branches of study, like convex and numerical analysis, were investigated. Furthermore, the Sin and Cos for the (CAS) wavelets used, to approximate the solution of linear integral equations (Yousefi and Banifatemi, 2006), Volterra integral equations of the second kind (Adibi and Assari, 2009), and optimal control systems by time-dependent coefficients (Abualrub et al., 2009).

Convert differential equation into an algebraic one is the main characteristic of the operational method and the integration is a core of the functional matrix starting by the integral property of the basic orthonormal matrix,  $\zeta(\hat{t})$  can write the following approximation:

$$\underbrace{\int_0^{\hat{t}} \int_0^{\hat{t}} \dots \int_0^{\hat{t}}}_{k} \psi(\hat{t})(d)^k \cong Q_{\psi}^k \psi(\hat{t}) \quad (\text{Eq.1})$$

Where  $\psi(\hat{t}) = [\bar{\psi}_0(\hat{t}) \ \bar{\psi}_1(\hat{t}) \ \dots \ \bar{\psi}_{m-1}(\hat{t})]^T$  in which the elements  $\bar{\psi}_0(\hat{t}), \bar{\psi}_1(\hat{t}), \dots, \bar{\psi}_{m-1}(\hat{t})$  are the discrete representation of essential functions which are orthogonal on the interval  $[0,1)$  and  $Q_{\psi}$  is the operational matrix for the integration of  $Q(\hat{t})$  [10] (Wu and Chen, 2003).

Yousefi and Banifatemi, 2006, suggested introducing the CAS waves first. CAS wavelets approximation method utilized to reduce the Fredholm integral equations to the solution of algebraic equations. The CAS wavelet operational matrix P of integration will be first presented, and a general procedure to generate this matrix P is given. CAS wavelet approximating method utilized

to reduce the integro-differential equation to the algebraic equations (Han and Shang, 2007). A wavelet-based method for evaluating the modal optimal control and trajectory of the bilinear system is proposed. The technique employs finite CAS wavelets to approximate modal control and state variables (Taher et al., 2009).

Presenting a computational method for solving nonlinear Fredholm integral equations: of the second kind which based on the use of Haar wavelets, for fractional-order which based on CAS (Cosine and Sine) wavelets, A new approach using CAS wavelets in combination with the collocation technique is proposed (Babolian and Shahsavaran, 2009; Saeedi et al., 2011; Ezzati and Najafalizadeh, 2012)

For fractional equations and wave waves, CAS: Using the series of CAS waves with an operational matrix to reduce fractional differential equations to the algebraic equation system. The solution to this system gives the approximate solution of the truncated finite "2K (2M + 1)" (Mingxu et al., 2013). A mathematical method is presented for the numerical solution of a class of differential equations with a weak single nucleus of a fractional system dependent on the Sin and Cos (CAS) waves and mass pulse functions (Mingxu and Jun, 2014). A novel numerical scheme for the approximate solutions of linear as well as nonlinear ordinary differential equations of fractional order with boundary conditions, this method combines Cosine and Sine (CAS) wavelets with Green function, called the Green-CAS method (Muhammad et al., 2019).

Presented a computational method for resolving integral boundary equations for singular logarithmic kernels, which occur as reformulations of a boundary value problem for Laplace's equation (Shamooshakya et al., 2014). The solution of time-varying systems obtained by using CAS wavelets, this method is based upon expanding various time functions in the system as their truncated CSA wavelets. The operational matrices of integration are utilized to reduce the resolution of time-varying systems to the solution of algebraic equations (Xiangyu, 2014). A based on CAS wavelets presented quadrature rules for the numerical solution of double and triple integrals with variable limits of integration (Rezabeyk and Maleknejad, 2015). Present a computational method for solving boundary integral equations with singular logarithmic kernels that occur as reformulations of a boundary value problem for Laplace's equation (Fathizadeh et al., 2017). Proposed a new operational matrix of differentiation using CAS wavelets, with the aid of

these matrices, the CAS wavelets method (CASWM) is developed for the integrodifferential equations (Shiralashetti and Kumbinaraiah, 2019). Solved this system numerically by finite elements method (G.F.E) method, and found that (G.F.E) method is faster than (F.D) method to reach equilibrium state for all  $\hat{t}$  and  $x$  values (Manaa and Qasim, 2019).

Therefore, this study aimed to highlight the CAS wavelets method and test the strength of this method by comparing the solution with a widely known and well-method, which is the Galerkin finite element method.

## 2. MATERIALS AND METHODS:

### 2.1. CAS wavelet method

CAS wavelets method can be written as:  $\tau_{\gamma,m}(\chi) = \tau(\rho, \gamma, m, \chi)$  Where  $\gamma = 1, 2, \dots, 2^\rho$ ,  $\rho, m$  a positive integer and  $\chi$  is the normalized time.

Orthonormal CAS wavelets are defined on the  $[0, 1]$  by:

$$\tau_{\gamma,m}(\chi) = \begin{cases} 2^{\frac{\rho}{2}} CAS_m(2^\rho \chi - \gamma + 1) & \text{for } \frac{\gamma-1}{2^\rho} \leq \chi < \frac{\gamma}{2^\rho} \\ 0 & \text{otherwise} \end{cases} \quad (\text{Eq. 2})$$

Where  $CAS_m(\chi) = \cos(2\pi m \chi) + \sin(2\pi m \chi)$ , and  $m \in \{-M, \dots, M\}$  the CAS wavelets are orthonormal for weight function  $W(x) = 1$ .

The CAS wavelets have the following form with  $m=0$ :

$$\tau_{\gamma,0}(\chi) = 2^{\frac{\rho}{2}} G_\gamma(\chi) = 2^{\frac{\rho}{2}} \begin{cases} 1 & \frac{\gamma-1}{2^\rho} \leq \chi < \frac{\gamma}{2^\rho} \\ 0 & \text{otherwise} \end{cases} \quad (\text{Eq. 3})$$

where  $\{G_\gamma(\chi)\}_{\gamma=1}^{2^\rho}$  is Block -Pulse functions (basis set) on the close interval  $[0, 1]$  (Lepik, 2007).

It can be defined as the integral of (Eq. 2) by CAS wavelets analytically as:

$$P_{2^\rho(2M+1),1}(\chi) = \int_0^\chi \tau_{\gamma,m}(\chi') d\chi' = \begin{cases} 0 & 0 \leq \chi < \frac{\gamma-1}{2^\rho} \\ \int_{\frac{\gamma-1}{2^\rho}}^\chi 2^{\frac{\rho}{2}}(\varpi) d\chi' & \frac{\gamma-1}{2^\rho} \leq \chi < \frac{\gamma}{2^\rho} \\ \int_{\frac{\gamma-1}{2^\rho}}^{\frac{\gamma}{2^\rho}} 2^{\frac{\rho}{2}}(\varpi) d\chi' & \frac{\gamma}{2^\rho} \leq \chi < 1 \end{cases}$$

Where

$$\varpi = \sin(2\pi m(2^\rho \chi' - \gamma + 1)) + \cos(2\pi m(2^\rho \chi' - \gamma + 1))$$

Then

$$P_{2^\rho(2M+1),1}(\chi) = \begin{cases} 0 & 0 \leq \chi < \frac{\gamma-1}{2^\rho} \\ 2^{\frac{\rho}{2}} \frac{1}{\varphi} (\sin(2\pi m(2^\rho \chi - \gamma + 1)) - \sin(2\pi m(\frac{\gamma-1}{2^\rho}))) & \frac{\gamma-1}{2^\rho} \leq \chi < \frac{\gamma}{2^\rho} \\ c \cos(2\pi m(2^\rho \chi - \gamma + 1)) - 2^{\frac{\rho}{2}} \frac{1}{\varphi} \cos(2\pi m(\frac{\gamma}{2^\rho})) & \frac{\gamma}{2^\rho} \leq \chi < 1 \end{cases}$$

Where  $\varphi = 2^{\rho+1} \pi m$

Founding the integration n times as:

$$P_{\lambda,u}(x) = \begin{cases} 0 & 0 \leq \chi < \frac{\gamma-1}{2^\rho} \\ 2^{\frac{\rho}{2}} \frac{(-1)^f u}{(\varphi)^u} \cos(2\pi m(2^\rho \chi - \gamma + 1)) & \frac{\gamma-1}{2^\rho} \leq \chi < \frac{\gamma}{2^\rho} \\ + 2^{\frac{\rho}{2}} \frac{(-1)^e u}{(\varphi)^u} \sin(2\pi m(2^\rho \chi - \gamma + 1)) & \frac{\gamma}{2^\rho} \leq \chi < 1 \\ - \sum_{jj=0}^{u-1} 2^{\frac{\rho}{2}} \frac{1}{jj!} \frac{(-1)^f u}{(\varphi)^{u-jj}} \left( \chi - \frac{\gamma-1}{2^\rho} \right)^{jj} & \\ \sum_{j=0}^{u-1} \frac{1}{j!} \left( \chi - \frac{\gamma}{2^\rho} \right)^j & \\ \left( 2^{\frac{\rho}{2}} \frac{(-1)^f u}{(\varphi)^u} \cos(2\pi m) + 2^{\frac{\rho}{2}} \frac{(-1)^e u}{(\varphi)^u} \sin(2\pi m) \right) & \\ - \sum_{jj=0}^{u-1} 2^{\frac{\rho}{2}} \frac{1}{jj!} \frac{(-1)^f u}{(\varphi)^{u-jj}} \left( \frac{1}{2^\rho} \right)^{jj} & \end{cases} \quad (\text{Eq. 4})$$

Where  $\varphi = 2^{\rho+1}\pi m$ , and

$$f_u = \begin{cases} 0 & \text{if } u = 3, 4, 7, 8, 11, 12, \dots \\ 1 & \text{if } u = 1, 2, 5, 6, 9, 10, \dots \end{cases}$$

And

$$e_u = \begin{cases} 0 & \text{if } u = 1, 4, 5, 8, 9, 12, \dots \\ 1 & \text{if } u = 2, 3, 6, 7, 10, 11, \dots \end{cases}$$

If  $u=0$  corresponds to CAS function  $\tau_{\gamma, m}(\chi)$  in (Eq. 2). To solve boundary value problems, substitute  $\chi = G$  in (Eq. 4). In some instances where  $u=1$ , finding (Lepik, 2007):

$$P_{\lambda, u}(x) = \begin{cases} 0 & 0 \leq \chi < \frac{\gamma-1}{2^\rho} \\ +2^{\frac{\rho}{2}} \frac{1}{\varphi} \sin(2\pi m(2^\rho G - \gamma + 1)) - \cos(2\pi m(2^\rho G - \gamma + 1)) & \frac{\gamma-1}{2^\rho} \leq \chi < \frac{\gamma}{2^\rho} \\ -2^{\frac{\rho}{2}} \frac{1}{\varphi} & \frac{\gamma}{2^\rho} \leq \chi < \frac{\gamma+1}{2^\rho} \\ 2^{\frac{\rho}{2}} \frac{1}{\varphi} (\sin(2\pi m) - \cos(2\pi m)) - 2^{\frac{\rho}{2}} \frac{1}{\varphi} & \frac{\gamma+1}{2^\rho} \leq \chi < \frac{\gamma+2}{2^\rho} \end{cases}$$

## 2.2. Approximation CAS Function

Expanded  $v(\chi)$  by CAS wavelets such that:

$$v(\chi) = \sum_{\lambda=0}^{\infty} z_{\lambda} \tau_{\lambda, m}(\chi), \quad \lambda = 0, 1, 2, 3, \dots, N$$

Hence:

$$Z_0 = \int_0^1 v(\chi) \tau_0(\chi) d\chi,$$

$$Z_{\lambda} = 2^j \int_0^1 v(\chi) \tau_{\lambda}(\chi) d\chi$$

(Eq. 5)

(Eq. 6) With the initial and boundary conditions:

$$\lambda = 2^j + \rho, \quad j \geq 0, \quad 0 \leq \rho < 2^j, \quad \chi \in [0, 1]$$

The integral square error E minimized as:

$$E = \int_0^1 \left[ v(\chi) - \sum_{\lambda=0}^{2^\rho-1} z_{\lambda} \tau_{\lambda}(\chi) \right]^2 d\chi, \quad \rho = 0, 1, 2, \dots, N \quad (\text{Eq. 7})$$

Any function  $v(\chi) \in L^2[0, 1]$  may be expanded using CAS wavelets as:

$$v(\chi) = \sum_{\lambda=0}^{2^\rho} z_{\lambda, m} \tau_{\lambda, m}(\chi) = z^T \tau(\chi) \quad (\text{Eq. 8})$$

Where  $m \in [-M, M]$  and  $Z, \tau(x)$  are matrices given by:

$$Z = [Z_{1, (-M)}, Z_{1, (-M+1)}, \dots, Z_{1, M}, Z_{2^\rho, (-M)}, Z_{2^\rho, (-M+1)}, \dots, Z_{2^\rho, M}]^T$$

$$\tau(x) = [\tau_{1, (-M)}(\chi), \tau_{1, (-M+1)}(\chi), \tau_{1, M}(\chi), \dots, \tau_{2^\rho, (-M)}(\chi), \tau_{2^\rho, (-M+1)}(\chi), \dots, \tau_{2^\rho, M}(\chi)]^T$$

; T transposes (Hariharan and Kannan, 2010).

## 2.3. Mathematical Model

Applying CAS wavelets method to solve nonlinear reaction-diffusion system which has the form (Kan-on, 1997):

$$\begin{aligned} \frac{\partial v}{\partial t_*} &= \varepsilon_1 \frac{\partial^2 v}{\partial \chi_*^2} + v[\alpha_1(\chi_*) - \beta_1 v - \delta_1 \sigma] \\ \frac{\partial \sigma}{\partial t_*} &= \varepsilon_2 \frac{\partial^2 \sigma}{\partial \chi_*^2} - \sigma[\alpha_2(\chi_*) - \delta_2 v] \end{aligned}$$

(Eq. 9)

$$v(\chi_*, 0) = v_0(\chi)$$

$$\sigma(\chi_*, 0) = \sigma_0(\chi)$$

$$\frac{\partial v}{\partial \chi_*} = \frac{\partial \sigma}{\partial \chi_*} = \frac{\partial v}{\partial \chi_*}(a, t) = \frac{\partial v}{\partial \chi}(b, t) = 0$$

$$\chi_* \in [a, b]$$

$$t \geq 0$$

(Eq. 10)

$v(\chi, \hat{t})$  represents the reaction type,  $\sigma(\chi, \hat{t})$  represents the diffusion type.  $\varepsilon_1, \varepsilon_2, \beta_1, \delta_1, \delta_2$  are positive constants.  $\alpha_1(\chi), \alpha_2(\chi)$  are the rates of growth of aspects,  $v_0$  and  $\sigma_0$  are constant interior solutions of (Eq. 9).

First normalize with regard to  $\chi_* \in [a, b]$  because CAS wavelets method defined for  $\chi \in [0, 1]$ , the variables changing as (Lou et al., 2006):

$$\chi = \frac{1}{L}(\chi_* - a), \quad \hat{t} = \hat{t}_* - 0, \quad L = b - a$$

(Eq. 9), (Eq. 10) becomes:

$$\frac{\partial v}{\partial \hat{t}} = \frac{\varepsilon_1}{L^2} \frac{\partial^2 v}{\partial \chi^2} + v[\alpha_1(L\chi + a) - \beta_1 v - \delta_1 \sigma]$$

$$\frac{\partial \sigma}{\partial \hat{t}} = \frac{\varepsilon_2}{L^2} \frac{\partial^2 \sigma}{\partial \chi^2} - \sigma[\alpha_2(L\chi + a) - \delta_2 v]$$

(Eq. 11)

And

$$v(\chi, 0) = v_0(\chi), \quad \sigma(\chi, 0) = \sigma_0(\chi)$$

$$\frac{\partial v}{\partial \chi} = \frac{\partial \sigma}{\partial \chi} = \frac{\partial v}{\partial \chi}(0, \hat{t}) = \frac{\partial v}{\partial \chi}(1, \hat{t}) = 0$$

$$\chi \in [0, 1]$$

$$\hat{t} \geq 0$$

(Eq. 12)

Suppose that,  $v_{\chi\chi}(\chi, \hat{t}), \sigma_{\chi\chi}(\chi, \hat{t})$  can extend the range of CAS waves as follows:

$$v_{\chi\chi}(\chi, \hat{t}) = \sum_{\lambda=0}^{2^p} \sum_{m=-M}^M z_s(\lambda) \tau_\lambda(x) = z_m^T \tau_m(x) \quad t \in (\hat{t}_s, \hat{t}_{s+1}]$$

$$\sigma_{\chi\chi}(\chi, \hat{t}) = \sum_{\lambda=0}^{2^p} \sum_{m=-M}^M z_s(\lambda) \tau_\lambda(x) = z_m^T \tau_m(x) \quad t \in (\hat{t}_s, \hat{t}_{s+1}]$$

(Eq. 13)

Where the elements  $z_{(m)}^T$  are constant in the subinterval

$$t_s = (s-1)\Delta\hat{t}, \Delta\hat{t} = \frac{T}{N} \quad \hat{t} \in (\hat{t}_s, \hat{t}_{s+1}]$$

$$s = 1, 2, 3, \dots, N, \hat{t} \in (0, T)$$

Integrating (Eq. 13) finding:

$$v_{\chi\chi}(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T \tau_m(\chi) + v_{\chi\chi}(\chi, \hat{t}_s)$$

$$\sigma_{\chi\chi}(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T \tau_m(\chi) + \sigma_{\chi\chi}(\chi, \hat{t}_s)$$

(Eq. 14)

$$v_\chi(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,1}(\chi) + [v_\chi(\chi, \hat{t}_s) - v_\chi(0, \hat{t}_s)] + v_\chi(0, \hat{t})$$

$$\sigma_\chi(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,1}(\chi) + [\sigma_\chi(\chi, \hat{t}_s) - \sigma_\chi(0, \hat{t}_s)] + \sigma_\chi(0, \hat{t})$$

(Eq. 15)

$$v(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,2}(\chi) + [v(\chi, \hat{t}_s) - v(0, \hat{t}_s)] + \chi[v(0, \hat{t}) - v(0, \hat{t}_s)] + v(0, \hat{t})$$

$$\sigma(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,2}(\chi) + [\sigma(\chi, \hat{t}_s) - \sigma(0, \hat{t}_s)] + \chi[\sigma(0, \hat{t}) - \sigma(0, \hat{t}_s)] + \sigma(0, \hat{t})$$

(Eq. 16)

The differential of equation (Eq.16) with respect  $\hat{t}$  can be writing:

$$\begin{aligned}v^*(\chi, \hat{t}) &= z_m^T P_{\lambda,2}(\chi) + x v_x^*(0, \hat{t}) + v^*(0, \hat{t}) \\ \sigma^*(\chi, \hat{t}) &= z_m^T P_{\lambda,2}(\chi) + \chi \sigma_\chi^*(0, \hat{t}) + \sigma^*(0, \hat{t})\end{aligned}\quad (\text{Eq. 17})$$

It can be reducing the boundary condition  $v_\chi^*(0, \hat{t})$  and  $v^*(0, \hat{t})$  in equation (Eq. 17) such that:

$$v^*(0, \hat{t}) = \frac{v(0, \hat{t}) - v(0, \hat{t}_s)}{(\hat{t} - \hat{t}_s)}$$

Then (Eq. 17) for  $v^*(\chi, \hat{t})$  becomes:

$$\begin{aligned}v^*(\chi, \hat{t}) &= z_m^T P_{\lambda,2}(\chi) + \chi \left[ \frac{v_\chi(0, \hat{t}) - v_\chi(0, \hat{t}_s)}{(\hat{t} - \hat{t}_s)} \right] \\ &\quad + \left[ \frac{v(0, \hat{t}) - v(0, \hat{t}_s)}{(\hat{t} - \hat{t}_s)} \right]\end{aligned}\quad (\text{Eq. 18})$$

Now, by substitute equations (Eq. 14) - (Eq. 18) in (Eq. 11), then get:

$$\begin{aligned}&z_m^T P_{\lambda,2}(\chi) + \frac{\chi}{\Delta t} \left[ v_\chi(0, \hat{t}) - v_\chi(0, \hat{t}_s) \right] - \frac{1}{\Delta t} \left[ v(0, \hat{t}) - v(0, \hat{t}_s) \right] \\ &= \frac{\varepsilon_1 \Delta t}{L^2} z_m^T \tau v(\chi, \hat{t}) + \frac{\varepsilon_1}{L^2} v_{\chi\chi}(\chi, \hat{t}) + v(\chi, \hat{t}_s) \\ &\quad \left[ \alpha_1(\chi L + a) - \beta_1 v(\chi, \hat{t}_s) - \delta_1 \sigma(\chi, \hat{t}_s) \right] \\ &z_m^T P_{\lambda,2}(\chi) + \frac{x}{\Delta t} \left[ \sigma_\chi(0, \hat{t}) - \sigma_\chi(0, \hat{t}_s) \right] - \frac{1}{\Delta t} \left[ \sigma(0, \hat{t}) - \sigma(0, \hat{t}_s) \right] \\ &= \frac{\varepsilon_2 \Delta t}{L^2} z_m^T \tau \sigma(\chi, \hat{t}) + \frac{\varepsilon_2}{L^2} \sigma_{\chi\chi}(\chi, \hat{t}) - \sigma(\chi, \hat{t}_s) \\ &\quad \left[ \alpha_2(\chi L + a) - \delta_2 v(\chi, \hat{t}_s) \right]\end{aligned}\quad (\text{Eq. 19})$$

The (Eq.19) is a linear system. The problem was found to be resolved (Eq. 16).

### 3. RESULTS AND DISCUSSION:

#### 3.1. Reducing the order boundary conditions:

Integrating equation (Eq. 17) to calculate

unknown term such as:

$$\begin{aligned}\int_0^1 v_\chi(\chi, t) d\chi &= \int_0^1 (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,1}(\chi) d\chi + \int_0^1 v_\chi(\chi, \hat{t}_s) d\chi \\ &\quad + \int_0^1 [v_\chi(0, \hat{t}) - v_{\chi\chi}(0, \hat{t}_s)] d\chi\end{aligned}$$

$$\Rightarrow v(1, \hat{t}) - v(0, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T D_{\lambda,1}(\chi) + [v(1, \hat{t}_s) - v(0, \hat{t}_s)] + [v_\chi(0, \hat{t}) - v_\chi(0, \hat{t}_s)]$$

$$\Rightarrow [v_\chi(0, \hat{t}) - v_\chi(0, \hat{t}_s)] = -(\hat{t} - \hat{t}_s) z_m^T D_{\lambda,1}(\chi) + [v(1, \hat{t}) - v(1, \hat{t}_s)] - [v(0, \hat{t}) - v(0, \hat{t}_s)]$$

(Eq. 20)

$$\text{Where } D_{\lambda,1}(\chi) = \int_0^1 P_{\lambda,1}(\chi) d\chi$$

By substitute (Eq. 20) in equations (Eq. 14) - (Eq. 18) about  $v(\chi, \hat{t})$  we get:

$$v_{\chi\chi}(\chi, \hat{t}) = (\hat{t} - \hat{t}_s) z_m^T \tau_m(\chi) + v_{\chi\chi}(\chi, \hat{t}_s) \quad (\text{Eq. 21})$$

$$\begin{aligned}v_\chi(\chi, \hat{t}) &= (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,1}(\chi) - (\hat{t} - \hat{t}_s) z_m^T D_{i,1}(\chi) \\ &\quad + [v(1, \hat{t}) - v(1, \hat{t}_s)] - [v(0, \hat{t}) - v(0, \hat{t}_s)] + v_\chi(0, \hat{t}_s)\end{aligned}$$

(Eq. 22)

$$\begin{aligned}v(\chi, \hat{t}) &= (\hat{t} - \hat{t}_s) z_m^T P_{\lambda,2}(\chi) + [v_\chi(\chi, \hat{t}_s) - v_\chi(0, \hat{t}_s)] \\ &\quad + \chi [-(\hat{t} - \hat{t}_s) z_m^T D_{i,1}(\chi) + [v(1, \hat{t}) - v(1, \hat{t}_s)] \\ &\quad - [v(0, \hat{t}) - v(0, \hat{t}_s)] + v(0, \hat{t}_s)]\end{aligned}\quad (\text{Eq. 23})$$

Now, differential (Eq. 23) by respect  $\hat{t}$ , then get:

$$\begin{aligned}v^*(\chi, \hat{t}) &= z_m^T P_{\lambda,2}(\chi) + \frac{1}{(\hat{t} - \hat{t}_s)} [v_\chi(\chi, \hat{t}_s) - v_\chi(0, \hat{t}_s)] + \frac{\chi}{(\hat{t} - \hat{t}_s)} \\ &\quad [-(\hat{t} - \hat{t}_s) z_m^T D_{\lambda,1}(\chi) + \frac{1}{(\hat{t} - \hat{t}_s)} [v(1, \hat{t}) - v(1, \hat{t}_s)] \\ &\quad - [v(0, \hat{t}) - v(0, \hat{t}_s)]]\end{aligned}$$

(Eq. 24)

Now, by substitute equations (Eq. 21) - (Eq. 24) in (Eq. 11), then get:

$$z_m^T P_{\lambda,2}(\chi) + \frac{1}{\Delta t} [v_\chi(\chi, \hat{t}_s) - v_\chi(0, \hat{t}_s)] + \frac{\chi}{\Delta t} [-\Delta t z_m^T D_{i,1}(\chi)] \\ + \frac{1}{\Delta t} [v(1, \hat{t}) - v(1, \hat{t}_s)] - [v(0, \hat{t}) - v(0, \hat{t}_s)] = \frac{\varepsilon_1 \Delta t}{L^2} z_m^T \tau_m(\chi) \\ + \frac{\varepsilon_1 \Delta t}{L^2} v_{\chi\chi}(\chi, \hat{t}_s) + v(\chi, \hat{t}_s) [\alpha_1(\chi) - \beta_1 v(\chi, \hat{t}_s) - \delta_1 \sigma(\chi, \hat{t}_s)]$$

Similarly, find  $\sigma(\chi, \hat{t}_s)$  then:

$$z_m^T P_{\lambda,2}(\chi) - x z_m^T D_{\lambda,1}(\chi) - \frac{\varepsilon_1 \Delta t}{L^2} z_m^T \tau_m(\chi) = -\frac{1}{\Delta t} [v_\chi(\chi, \hat{t}_s) \\ - v_\chi(0, \hat{t}_s)] - \frac{1}{\Delta t} [v(1, \hat{t}) - v(1, \hat{t}_s)] + [v(0, \hat{t}) \\ - v(0, \hat{t}_s)] + \frac{\varepsilon_1 \Delta t}{L^2} v_{\chi\chi}(\chi, \hat{t}_s) + v(\chi, \hat{t}_s) \\ [\alpha_1(\chi) - \beta_1 v(\chi, \hat{t}_s) - \delta_1 \sigma(\chi, \hat{t}_s)] \\ z_m^T P_{\lambda,2}(\chi) - x z_m^T D_{\lambda,1}(\chi) - \frac{\varepsilon_2 \Delta t}{L^2} z_m^T \tau_m(\chi) = -\frac{1}{\varepsilon_1 \Delta t} [\sigma_\chi(\chi, \hat{t}_s) \\ - \sigma_\chi(0, \hat{t}_s)] - \frac{1}{\Delta t} [\sigma(1, \hat{t}) - \sigma(1, \hat{t}_s)] + [\sigma(0, \hat{t}) - \sigma(0, \hat{t}_s)] \\ + \frac{\varepsilon_2 \Delta t}{L^2} \sigma_{\chi\chi}(\chi, \hat{t}_s) - \sigma(\chi, \hat{t}_s) [\alpha_2(\chi) - \delta_2 v(\chi, \hat{t}_s)]$$

(Eq. 25)

### 3.2. Numerical results and Discussion

solve (Eq. 11) by using (Eq. 25) and the exact solution such that (Lou and et al., 2006):

$$v(\chi, 0) = \frac{\alpha_1}{\beta_1} + \frac{1}{(\alpha_1 - \alpha_2)\beta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \left\{ \right. \\ \sigma(\chi, 0) = \frac{1}{(\alpha_2 - \alpha_1)\delta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \left. \right\}$$

(Eq. 26)

$$\text{Where } \mu = \frac{\alpha_1 - \alpha_2}{\varepsilon_1 - \varepsilon_2} < 0, \quad \alpha_1, \alpha_2 > 0$$

$$v(\chi, 0) = v_0(\chi) \\ \sigma(\chi, 0) = \sigma_0(\chi) \\ \frac{\partial v}{\partial \chi} = \frac{\partial \sigma}{\partial \chi} = \frac{\partial v}{\partial \chi}(0, \hat{t}) = \frac{\partial v}{\partial \chi}(1, \hat{t}) = 0 \\ 0 \leq \chi \leq 1 \\ t \geq 0$$

(Eq. 27)

Thus will found:

$$v(\chi, \hat{t}_s) = v(\chi, 0) = \frac{\alpha_1}{\beta_1} + \frac{1}{(\alpha_1 - \alpha_2)\beta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \left\{ \right. \\ \sigma(\chi, \hat{t}_s) = \sigma(\chi, 0) = \frac{1}{(\alpha_2 - \alpha_1)\delta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \left. \right\}$$

$$v_\chi(\chi, \hat{t}_s) = v_\chi(\chi, 0) = \frac{\partial}{\partial \chi} \frac{\alpha_1}{\beta_1} + \frac{1}{(\alpha_1 - \alpha_2)\beta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \left\{ \right. \\ \sigma_\chi(\chi, \hat{t}_s) = \sigma_\chi(\chi, 0) = \frac{\partial}{\partial \chi} \left[ \frac{1}{(\alpha_2 - \alpha_1)\delta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \right] \left. \right\}$$

$$v_{\chi\chi}(\chi, \hat{t}_s) = v_{\chi\chi}(\chi, 0) = \frac{\partial^2}{\partial \chi^2} \left[ \frac{\alpha_1}{\beta_1} + \frac{1}{(\alpha_1 - \alpha_2)\beta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \right] \left\{ \right. \\ \sigma_{\chi\chi}(\chi, \hat{t}_s) = \sigma_{\chi\chi}(\chi, 0) = \frac{\partial^2}{\partial \chi^2} \left[ \frac{1}{(\alpha_2 - \alpha_1)\delta_1} \delta_2 \sin(\sqrt{-\mu\varepsilon_1}\chi) \right] \left. \right\}$$

(Eq. 28)

Comparison of the numerical solution and the exact solution by us (Lou and et al., 2006):

$$v(\chi, 0) = \frac{1}{10} \sin^2\left(\frac{24}{10} \pi \chi\right) + \sin^2\left(\frac{-5}{100} \pi \chi\right) \quad \chi \in [0, L] \\ \sigma(\chi, 0) = \frac{1}{10} \sin^2\left(\frac{24}{10} \pi \chi\right) + \sin^2\left(\frac{-5}{100} \pi \chi\right) \quad \chi \in [0, L]$$

Where L=0.5 and time step

$$\Delta t = 0.1, \varepsilon_1 = \varepsilon_2 = 0.001, \theta = 0.5, \alpha_1 = 1, \alpha_2 = 0.06,$$

$\beta_1 = \delta_1 = \delta_2 = 1$  the results are given in Table 1 and Figures 1 and 2.

Where L=0.5 is step size and time step

$$\Delta t = 0.1, \varepsilon_1 = \varepsilon_2 = 0.001, \theta = 0.5, \alpha_1 = 1, \alpha_2 = 0.01,$$

$\beta_1 = \delta_1 = \delta_2 = 0.0001$  and M=21 the results given in Table 2 and Figures 3 and 4.

Table 3 represents a comparison of the system's absolute errors (Eq. 11) between the CAS and finite element results with the exact solution. Noted the calculation of the CAS method in Table 2 We chose a value  $\beta_1, \delta_1, \delta_2$  close to zero which is,  $\beta_1 = \delta_1 = \delta_2 = 0.0001$ , while we took the value  $\beta_1 = \delta_1 = \delta_2 = 0$  in the calculation of the finite element method, because when calculating in the CAS method and when one of them  $\beta_1 = \delta_1 = \delta_2 = 0$  an appears in the solution amount is not defined.

From solving nonlinear partial differential equations for Reaction-diffusion Systems numerically by using the CAS method. "This

method found that it is better and faster for all the values for  $\hat{t}$  and  $x$ . It also found that it is converging towards steady-state solutions faster than and loses steps over time". As well, the CAS method converges to an exact solution faster when growing  $\varepsilon_1$  and  $\varepsilon_2$  and decreasing  $L$ . When  $\hat{t}$  is reduced, the solution will be quick to arrive at the real solution.

Finally, the comparison between the CAS methods and the finite elements was found the solution converged but clear preference for the CAS method on the finite element method, as shown in Tables 1 - 3 and Figures 1 - 4.

#### 4. CONCLUSIONS:

CAS wavelet method has been successfully applied to solve a coupled system of nonlinear Reaction-diffusion systems. It has been shown that the CAS wavelets method is quite capable and suited for finding exact solutions. The consistency of the method gives this method wider applicability. By comparing the numerical solution of the nonlinear Reaction-diffusion system and using the CAS wavelets and finite element methods with the exact solution, it was found that the CAS wavelets method is the most accurate and fastest way to reach the exact solution. Maple 18 was used to carry out the computations. Finally, it is worth noting that this method is clear and concise, and can be applied to nonlinear PDF equations in engineering and applied science.

#### 5. ACKNOWLEDGEMENTS:

"The authors are very grateful to the University of Mosul / College of Basic Education for their provided facilities, which helped to improve the quality of this work."

### RESUMO

A gestão de resíduos sólidos urbanos (RSU) parece ser um dos principais problemas ecológicos atualmente. A seleção de locais para o descarte de resíduos sólidos municipais ou de instalações de utilização de resíduos é um dos aspectos mais controversos do gerenciamento de resíduos. O objetivo do presente estudo foi desenvolver uma metodologia para avaliar a proteção natural do ambiente geológico contra contaminação na implementação de grandes projetos ecológicos devido à alocação de instalações de utilização de RSU. O caso do Distrito Federal Central da Rússia (CFD) foi tomado como exemplo. A adequação dos territórios para o descarte de resíduos sólidos municipais é avaliada de acordo com a presença de depósitos pouco permeáveis na seção geológica e seu modo de ocorrência. Um “mapa de CFD de zoneamento geológico de engenharia pelas condições de alocação de locais de descarte de RSU e instalações de utilização” foi compilado na escala 1:2500000. O mapa fornece uma indicação geral da adequação dos locais planejados para a eliminação de resíduos na região considerada e mostrou que, para a maior parte do território, a alocação de instalações de manejo e descarte de RSU exige a adoção de medidas adicionais para a proteção geoambiental da contaminação.

### ABSTRACT

The management of municipal solid waste (MSW) appears to be one of the major ecological problems at present. Selecting sites for the disposal of municipal solid wastes or waste utilization facilities is one of the most contentious aspects of waste management. The present study aimed to develop the methodology to assess the natural protection of the geological environment from contamination upon the implementation of large ecological projects due to the allocation of MSW utilization facilities. The case of the Central Federal District of Russia (CFD) is taken as an example. The suitability of territories for municipal solid waste disposal is assessed according to the presence of weakly permeable deposits in the geological cross-section and their occurrence mode. A “map of engineering geological zoning CFD by the conditions of allocation MSW disposal sites and utilization facilities” has been compiled to a scale 1:2500000. The map gives a general indication of the suitability of the planned sites for waste disposal within the regarded region and showed that, for the bulk of territory, the allocation of MSW disposal and management facilities requires undertaking additional measures for the geoenvironmental protection from contamination.

**Keywords:** *Municipal solid waste, Waste management, Waste storage, and reprocessing facilities, Favorability of geoenvironment, Engineering geological zoning and mapping.*

### 1. INTRODUCTION:

The management of municipal solid waste appears to be one of the significant ecological problems at present. A lot is said about how to

solve the issue (Khmelchenko, 2018; Osipov, 2019). Selecting sites for the disposal of municipal solid wastes or waste utilization facilities is one of the most contentious aspects of waste management. Experts all over the world are

attracted to research aimed at providing safe and environmental-friendly waste management (Cremiato, Mastellone, Tagliaferri, Zaccariello, & Lettieri, 2018; Nakhaei, Amiri, Rezaei, & Moosaei, 2015; Ogola, Chimuka, & Tshivhase, 2011; Ogola *et al.*, 2011; Yannah, Martens, Van Camp, & Walraevens, 2019). The complexity of the municipal solid waste (MSW) storage problem results, above all, from being multidisciplinary, that is, many social, economic, technical, and environmental issues must be taken into consideration. A lot of works have proven the necessity of performing multicriteria analysis for waste disposal site selection (Ghobadi, Taheri, & Taheri, 2017; Khan & Samadder, 2014; Kontos, Komilis, & Halvadakis, 2005; Rahmat *et al.*, 2017). Lately, in many countries around the world, the multicriteria approach including the hierarchical analytical process (AHP) as well as the more complex analytic network process (ANP) combined with geo-informational system (GIS) technologies are used for waste disposal site selection, which has proved their efficiency in finding a suitable and appropriate locations (Alanbari, Al-Ansari, & Jasim, 2014; Aydi, Zairi, & Dhia, 2013; Chang, Parvathinathan, & Breeden, 2008; Charnpratheep, Zhou, & Garner, 1997; Deswal & Laura, 2018; El Maguiri, Kissi, Idrissi, & Souabi, 2016; Güler & Yomralioğlu, 2017; Khodaparast, Rajabi, & Edalat, 2018).

Engineering geological conditions are one of the criteria involved in selecting an appropriate site, and in practice is one of the last taken into consideration. Priority is given to the distance from settlements and water reservoirs (remoteness), as well as natural reserves and protected areas (The State Duma, 1998). The geological environment degrades much more slowly than surface features do. At the same time, geological environment, that is, rocks and groundwater, can accumulate hazardous components for a long time and become prerequisites for future ecological disasters for future generations. By underestimating the impacts waste disposal has on the geoenvironment now, we create danger for environmental safety in the future.

Storage at disposal sites remains to be the primary method of municipal solid waste treatment in Russia. The current waste management system cannot cope with a large amount of waste produced. The problem of waste management is most acute in the Central Federal District (CFD) of the Russian Federation, which covers an area of more than 650 thousand sq. km and includes 18 oblasts. This is one of the most densely populated and industrially developed regions of Russia. At

present, over 90 billion tons of waste have accumulated in this area (VSEGEI, 2018). Above 1000 waste disposal facilities, that is, landfills and waste disposal sites, exist there, with the bulk of them not included in the national registration list (The Government of the Russian Federation, 2016).

One of the ways to solve the waste-management issue in Central Russia has been the construction of a limited number of extensive, sophisticated engineering facilities uniting an incinerator plant, a waste-reprocessing plant, and waste disposal (Ekzaryan, 2018; Kashperiyuk, Makeeva, Akanov, Nikitina, & Podlesnykh, 2018). Such industrial complexes already exist in many well-developed countries. Sites for the allocation of such complexes are typically selected on the basis of sanitary standards, which constrain landfill allocation depending on the distance from settlements and water bodies, as well as topographic, geological and hydrogeological conditions (Djokanović, Abolmasov, & Jevremović, 2016; El Maguiri *et al.*, 2016; Ministry of Health of the Russian Federation, 2001; Zelenović Vasiljević, Srdjević, Bajčetić, & Vojinović Miloradov, 2012).

In terms of geology and hydrogeology, territories suitable for waste disposal include those where weakly permeable clay layers occur at the top of a geological massif, and the groundwater lies deeper than two meters below the surface. The presence of thick clay strata in the upper part of the geologic massif appears to be the primary condition of territory favorability for the allocation of waste management facilities because these strata prevent the permeating of contamination from the surface to the underlying aquifers. Experience demonstrates that ignorance of this requirement results in serious undesirable ecological consequences (Dzhamalov, Medovar, & Yushmanov, 2018; Khmelchenko, 2018; Zaikanov, Zaikanova, & Buldakova, 2018).

For the CFD of the Russian Federation, the conditions (parameters) of natural protection of the geological environment from contamination have been analyzed, the principal types of geological-hydrogeological conditions have been distinguished, and the criteria of assessing the favorability of the territory for the implementation of combined projects in waste management have been suggested.

The present study aimed to develop the methodology to assess the natural protection of the geological environment from contamination upon the implementation of large ecological

projects due to the allocation of MSW utilization facilities. The case of the Central Federal District of Russia is taken as an example.

## 2. MATERIALS AND METHODS:

### 2.1. Conceptual model of Engineering Geological Assessment of the Central Russia territory for the allocation of municipal solid waste treatment facilities

Engineering geological assessment of potential sites for waste disposal proceeds from the idea that the occurrence of natural barriers in the geological cross-section can prevent contaminations from penetrating the surface down to the geological strata and groundwater. This prevention significantly enables the preservation of favorable ecological conditions around waste disposal sites and waste treatment facilities. Clay strata operate as such natural barriers. Engineering geological studies consider the presence of thick clay strata in the upper part of the geological massif to be the main condition of territory suitability for the allocation of the waste treatment facilities (Goldberg, 1987).

Figure 1 lists the main steps of the methodology of territory assessment in Central Russia. In terms of structural geology, CFD is located within the Russian platform, within which the upper part of the geological cross-section is composed of various stratigraphic and lithological sedimentary rock complexes of different ages. To a depth of 50–60 m, the entire diversity of these complexes may be subdivided into several types depending on their lithology, age, and the degree of water content in the pre-Quaternary and Quaternary soils and rocks (Komarov, 1978; Leonenko, Sidorenko, & Shik, 1971).

Mapinfo computer tools were used to create two auxiliary layers; one of the layers showing the pre-Quaternary rock complexes of different permeability and water content, and the other, the complexes of Quaternary deposits. The formal superposition of these layers permitted us to reveal their possible combinations. For each combination, the typical geological cross-section (column) was built, showing the layers of different age, lithological composition, and permeability. The input data for the compilation of these information layers and cross-sections included the small-scale archive geological maps for the Central Russia territory and other publications. In this work, we used the map data from the GIS atlas "The bowels of Russia" compiled at A.P. Karpinsky Russian Geological Research Institute (VSEGEI)

and the State geologic map of the Russian Federation to a scale 1:1000000 (VSEGEI, 2019; VSEGEI & Pogrebitsky, 1999).

Each type of geological structure (a typical geological cross-section) was referred to a certain category of territory suitability (a taxon) depending on the presence of low-permeable Quaternary and pre-Quaternary layers and the depth of their occurrence. Five taxons were distinguished corresponding to favorable, conventionally favorable, conventionally unfavorable, unfavorable and very unfavorable conditions from the viewpoint of MSW treatment projects. The assessment was performed proceeding from the geological structure depending on the mode of occurrence of low-permeable deposits in the upper part of geological massif.

The resultant zoning map manifests the outlines and indices of all types of geological structure, and the regions of different suitability (favorability) categories are distinguished in color (according to the traffic light principle). Thus, the map represents a highly informative document presenting not only the estimation criteria but also the generalized geological characteristics of each taxon.

### 2.2. Assessment of natural protection of the geological environment

The natural protection of the geological environment from contamination coming from the surface was assessed depending on the presence of low-permeable deposits (capable of protecting the geological environment from contamination penetrating from the surface) in the geological cross-section of pre-Quaternary and Quaternary deposits.

The pre-Quaternary deposits are subdivided into:

- low-permeable clay layers from the Jurassic age;
- unevenly permeable chalk and marl from the Cretaceous era and aleurolite-argillite gypsiferous rocks and gypsum from the Permian and Triassic ages;
- high-permeable sand and sandstone from the Neogene, Paleogene and Cretaceous ages;
- terrigenous-carbonate rocks from the Devonian and Carboniferous ages.

The spatial position of these complexes is shown on the first auxiliary layer compiled in Mapinfo format.

The analysis of Quaternary deposits was based on the presence of low-permeable loams of different genetic types and their position in the geological massif (Kashperuk *et al.*, 2018; Kozliakova, Kozhevnikova, Anisimova, & Eremina, 2020; Kozlovskiy, Mamaev, & Stol'nikova, 2020). Among Quaternary deposits, moraine loam forms the main low-permeable complex. On the second auxiliary information layer, the territories are outlined, where these soils lie at the surface or under alluvial and fluvio-glacial sand. We have also defined the territories where mantle loam and sandy loam manifest a considerable stretch and thickness.

Superposition of the two auxiliary information layers resulted in 18 types of ground massifs depending on the stratigraphic and lithological specifics and the water-content of pre-Quaternary and Quaternary complexes. These types formed the basis for the resultant estimation zoning of territory by the degree of favorability for allocation of MSW treatment facilities and disposal sites (Table 1).

A schematic column was built for each zoning taxon (Figure 2), explaining the mode of occurrence of the distinct geological and lithological complexes differing in its permeability. It can be distinguished: water-bearing and high-permeable deposits; low water-bearing and unevenly water-saturated deposits; and aquicludes or low-permeable deposits. In the geological cross-sections, the color stands for water content and water permeability, whereas the hatch designates stratigraphy and lithology.

### 3. RESULTS AND DISCUSSION:

The typification of the Central Russian territory according to the favorability of allocating MSW treatment facilities and disposal sites is a result of the research performed (Table 2). The general small-scale (1:2500000) map of engineering geological zoning was compiled (Figure 3).

Favorable ground massifs are considered to be those that include two aquiclude strata, that is, the Quaternary moraine loam occurs close to the surface and the Jurassic clay. Thus, the quaternary and the Mesozoic water-bearing complexes are isolated from each other, and the geological environment is protected from contamination coming from the surface. These

regions are outlined locally, mainly in the northern part of the territory.

It is recognized territories as conventionally favorable if the Quaternary moraine loam occurs at the surface, being underlain by high-permeable deposits. The degree of protection of the geoenvironment from surface contamination is controlled by the moraine loam thickness at these sites. The areas of this kind are outlined in the northwest of the territory and on the interfluvial surfaces in its central part.

Conventionally unfavorable sites are those where ground massif is composed of sandy-clayey Quaternary deposits without any continuously stretching low-permeable layers underlain by the Jurassic clay strata. The groundwater aquifer is prone to pollution at such sites, and the degree of protection of deep horizons is controlled by the thickness and depth of occurrence of the Jurassic clay. These regions are registered in the northern and eastern parts of the Moscow region.

Sites are classified as unfavorable if the geological massif is composed of high-permeable Quaternary and pre-Quaternary deposits with locally spread low-permeable layers. The geological environment in these areas is virtually unprotected from contamination. These areas include the bulk of the territory in the southwest and in the east of the Central Federal district and local sites in the north.

Very unfavorable sites are those where the geological massif consists of only highly permeable and water-saturated deposits. At these sites, the geological environment is not isolated from contamination coming from the surface. These sites are usually confined to river valleys, with alluvial deposits immediately overlying Carboniferous and Devonian carbonate rocks; or to the regions where Paleogene-Neogene sand and sandstone occur.

As shown above, the geological conditions as one of the criteria for site selection of MSW facilities requires special analysis due to substantial spatial variability. When characterizing sites, it appears not enough just to mark the soil and rocks occurring at the surface in the given territory and to point out the groundwater depth, as it is usually done upon zoning for waste disposal site selection (Djokanović *et al.*, 2016; El Maguiri *et al.*, 2016).

By assessing MSW disposal sites by the presence of one or several low-permeable layers in the geological cross-section, we are able to take

into account the hazards of the contamination of the ground massif and groundwater when assessing the territory.

The map of the geological engineering zoning compiled based on the proposed typification gives a general idea about the favorability of planned sites for the allocation of MSW reprocessing facilities in the Central Federal district. It is compiled in a digital form, and it should be considered as an informational layer to be integrated into the general GIS based on the multicriteria principle for making decisions on waste disposal site selection. For the subsequent transition to the quantitative methods of multicriteria analysis, it appears easy to assign scores to taxons according to their favorability degree (Bottero & Ferretti, 2011; Chang *et al.*, 2008).

Besides, the zoning map has its own value as an individual document reflecting the present-day state of the waste-disposal problem in Central Russia. The map analysis proves that the entire territories of Kursk and Belgorod oblasts are related to very unfavorable and unfavorable categories. That means no large sites can be identified within these territories, where the ground massif manifests natural protection from the contamination coming from the surface. In Bryansk, Kaluga, Orel, Lipetsk, Tambov, Voronezh, Ryazan, Vladimir and Kostroma oblasts, unfavorable and very unfavorable regions occupy more than half of the oblast territory.

Thus, for most of the Central Federal district, the construction of waste management facilities requires additional engineering measures for the protection of the geological environment from contamination. At present, many MSW disposal sites and landfills have been arranged within this territory without taking the geological conditions into account.

To minimize the risks of contamination, the specifics of the geological environment should be analyzed at the early stages of compiling waste-management GIS. In doing so, the geological environment should be considered as a massif of a complex structure with variable properties, as it is done in our research for the Central Russian region. The existing experience in GIS compilation demonstrates that the geological block is developed inadequately as a rule (Ali Jalil Chabuk, Nadhir Al-Ansari, Hussain Musa Hussain, Sven Knutsson, & Roland Pusch, 2016; Aragonés-Beltrán, Pastor-Ferrando, García-García, & Pascual-Agulló, 2010; Ghobadi *et al.*, 2017; Khan & Samadder, 2014; Khodaparast *et al.*, 2018;

Kontos *et al.*, 2005). As proceeds from the analysis of international publications, the multicriteria approach to selecting waste disposal sites, which is commonly employed all over the world, unfortunately, underestimates the geological conditions of the territories being considered. At best, only the soil and rocks of the uppermost geological layer are taken into consideration, whereas the entire geological cross-section to a depth of anthropogenic impact is not considered (Deswal & Laura, 2018; El Maguiri *et al.*, 2016; Güler & Yomralioğlu, 2017; Rahmat *et al.*, 2017). It is suggested the typification of the geological environment according to the suitability (favorability) for the safe and reliable MSW disposal to be used at the early stage of planning the allocation of MSW treatment facilities. It permits, on the one hand, the capacity to formalize the assessment of geological conditions and, on the other hand, to take into account their variability by area and by the depth most comprehensively.

#### 4. CONCLUSIONS:

The assessment of the suitability of a territory for the allocation of MSW utilization facilities and waste disposal sites should obligatorily take into account the degree of natural protection from contamination provided by the geological environment.

The degree of natural protection of the geological environment is assessed proceeding from the presence or absence in the geological massif of one or several low permeable rock strata, preventing the penetration of contaminants from the surface to groundwater aquifers, as well as the thickness and the depth of occurrence of these strata.

Engineering geological zoning, including typifying territories by the specific features of geological and hydrogeological structures, assessing the favorability of each distinct type, and zoning territories according to the geological criteria to determine their suitability to contain MSW utilization facilities and waste disposal sites appears to be a versatile method for assessing the natural protection of geological environment in vast territories.

To conclude, it is worth noting that small-scale maps or estimation schemes of geological engineering zoning can give a general idea of the suitability of the planned places for the allocation of waste disposal complexes. They point out the possible vital sites for further investigation and give an overview of the volume of the necessary

additional measures on geoenvironment protection from contamination upon the construction and running of these engineering facilities. These maps and schemes should be used at the early stages of projecting the MSW storage and management complexes.

**RESUMO**

No Cazaquistão, devido ao fortalecimento do papel geopolítico na arena internacional e ao desenvolvimento industrial ativo, os impactos ambientais negativos se intensificaram nos últimos anos. Muitas regiões são ambientalmente desfavoráveis e correm o risco de um aumento na incidência de vida nessas condições da população. Inúmeros desvios na saúde da população criam condições para o polimorfismo genético e o crescimento de certos grupos de doenças característicos de regiões com poluição ambiental. A poluição ambiental a longo prazo é a razão do aumento da taxa do processo de mutação e do volume da carga genética na população humana. O objetivo deste estudo é mostrar a influência de fatores ambientais dominantes em regiões distantes do Cazaquistão sobre distúrbios citogenéticos no corpo da geração mais jovem. Estudantes de diferentes escolas com idades entre 16 e 18 anos que moram perto do local de teste de Semipalatinsk, na região leste do Cazaquistão e na região de Aral, na região de Kyzylorda, participaram dos estudos. Os resultados do estudo mostram que as células epiteliais orais em dois terços dos adolescentes examinados que vivem em condições ambientalmente desfavoráveis, próximas ao local do teste de Semipalatinsk ou na região do Mar de Aral, no Cazaquistão, revelaram uma ampla gama de distúrbios citogenéticos. A maior porcentagem de violações, associada à formação de micronúcleos, protrusões e apoptose, foi detectada em estudantes urbanos que vivem a 150 km do local do teste de Semipalatinsk. Ao comparar os dados de estudantes urbanos e rurais, foi revelado o desenvolvimento predominante de desordens citológicas, como destruição nuclear (cariorexia, cariólise e apoptose) em adolescentes rurais, o que indica o impacto negativo contínuo do local de teste de Semipalatinsk fechado e a salinização do Mar de Aral sobre a saúde da geração mais jovem de crianças.

**ABSTRACT**

In Kazakhstan, due to the strengthening of the geopolitical role in the international arena and active industrial development, negative environmental impacts have intensified in recent years. Many regions are environmentally unfavorable and carry the risk of an increase in the incidence of living in these conditions of the population. Numerous deviations in the health of the community create the conditions for genetic polymorphism and the growth of certain groups of diseases characteristic of regions with environmental pollution. Long-term environmental pollution is the reason for the increase in the rate of the mutation process and the volume of the genetic load in the human population. The purpose of this study is to show the influence of dominant environmental factors in distant regions of Kazakhstan on cytogenetic disturbances in the body of the younger generation. Students from different schools aged 16 to 18 years living near the Semipalatinsk test site of the East Kazakhstan region and in the Aral region of the Kyzylorda region took part in the studies. The results of the study show that the oral epithelial cells in two-thirds of the examined adolescents living in environmentally unfavorable conditions either near the Semipalatinsk Test Site or in the Aral Sea region of Kazakhstan revealed a wide range of cytogenetic disorders. The most significant percentage of violations associated with the formation of micronuclei, protrusions, and apoptosis, was detected in urban students living 150 km from the Semipalatinsk Test Site. When comparing the data of urban and rural students, the predominant development of cytological

disorders was revealed, such as nuclear destruction (karyorrhexis, karyolysis, and apoptosis) in rural adolescents, which indicates the ongoing negative impact of the closed Semipalatinsk Test Site and the salinization of the Aral Sea on the health of the younger generation of children.

**Keywords:** Ecology, Adolescent health, Semipalatinsk Test Site, Priaralye, Cytogenetic disorders.

## 1. INTRODUCTION:

Currently, there is an increase in the incidence of environmental pollution, with industrial waste entering the water, soil, air, and food. Changes in the quality of the living environment lead to the disruption of numerous evolutionarily established mechanisms of interaction between man and nature. Such shifts violate the ecology of the external and internal environments of a person and lead to disease (UNECE Environment Division, 2013).

In Kazakhstan, environmental problems also pose dangerous risk elements for human life and health, including the long-term effect of radioactive contamination in the area near the former Semipalatinsk Nuclear Test Site and the pollution of the environment with toxic compounds as the Aral Sea dries up. These problems, due to their significance, have a global resonance (Nazarbayev *et al.*, 2016).

The East Kazakhstan Region in Kazakhstan has existed since 1932 and includes the territories of 15 districts. The Altai and Tarbagatai mountains are located in the region, and it contains more than 885 rivers, carrying over 40% of all water reserves in Kazakhstan. About 1.5 million inhabitants of more than 15 nationalities live here (Nazarbayev *et al.*, 2016). Over the past 20 years, the mortality rate from neoplasms among the adult population in the East Kazakhstan Region has been 20-30% higher than the average national level (Yan, 2019). Radioactive pollution of the environment continues to be considered the cause for this high mortality, the sources of which are the Semipalatinsk Test Site and the enterprises of the nuclear-industrial complex. For 40 years, until 1989, about 456 nuclear tests were carried out at the abovementioned test site, including 30 ground and 86 air tests (Nazarbayev *et al.*, 2016). The consequences of such tests are a still increased level of radioactive infection and genetic mutations, with a high incidence for the population of several generations living near the landfill (Grosche *et al.*, 2017). With industry concentrated in this region, 154 industrial enterprises annually emit 294 thousand tons of toxic chemicals into the environment. For example, in the territory of

Semey, the maximum concentration of heavy metals exceeds the permissible standards for copper, lead, and chromium by 100 times, for zinc by 300 times, and for cobalt and nickel by 50 times (Gazaliev, 2016). Currently, at the state level, a number of programs have been adopted to improve the region's ecology and disease prevention measures (Nazarbayev *et al.*, 2016). As a result of sanitary and hygienic standards over the past ten years, the incidence rates of many diseases in the population have decreased in the Semipalatinsk region. Still, over the years, the level of endocrine disorders has remained 30-40% higher than both the regional average and the national average (in 2011, 1255.5 in Semey vs 954.3 in the republic; in 2017, 1389.7 in Semey vs 976.4 in the republic) (Ministry of Health of the Republic of Kazakhstan, 2011).

Regarding the Kazakhstani part of the Aral Sea region, the following problems should be highlighted. The intensive development of irrigation since 1960 in both Kazakhstan and Central Asia as a whole has led to a steady decline in the level of the Aral Sea, the deterioration of ecosystems, the development of aridization, and significant desertification in the region. As a consequence of such processes, there have emerged problems, including a high content of mineral salts in the water and soil and the depletion and pollution of water resources of the Aral Sea region (Crighton, Barwin, Small, & Upshur, 2011; Novikov & Kelly, 2017; White, 2013).

The environmental problems of the region have led to wide-scale and regional climate changes in large areas of the country due to an increase in the greenhouse effect, an increase in the concentration of carbon dioxide in the atmosphere, and salt and dust emissions, which have impacted human living conditions in the Aral Sea region. According to a number of authors, in the Kazakhstani part of the Aral Sea region, over the past 20 years, demographic processes have significantly deteriorated due to an increase in total and infant mortality. The leading causes of this mortality increase are diseases of the circulatory system and respiratory and digestive organs (Ni, Tonkobaeva, & Ilyasova, 2013; Toleutay, 2017).

In recent years, according to official statistics, in the Republic of Kazakhstan, there has been a general decrease in the incidence of disease in the population (Ministry of Health of the Republic of Kazakhstan, 2011, 2017, 2018). This has been primarily due to the widespread provision of modern equipment to medical facilities in cities and outpatient networks in districts, which has increased the diagnostic capabilities of local health care. Nevertheless, in many regions of the country, a high incidence of disease in the population remains, which can be explained by the environmental pollution of the living environment. Environmental pollution is one of the main reasons for the increase in the rate of the mutation process and the volume of the genetic load in human and animal populations, as evidenced by the growth in the number of hereditary and multifactorial diseases, congenital pathologies, and malformations, which are especially pronounced in ecologically disadvantaged regions (Landrigan & Fuller, 2015).

One of the indicators of the state of the body is cytogenetic homeostasis, which is determined using a micronucleus test, which, essentially, calculates the frequency of cells with micronuclei in the epithelial cells of the buccal epithelium. The micronuclear test is included in many manuals (Hayashi, 2016) and is actively used in many studies, in particular, to determine the environmental load that can cause damage to the genetic apparatus in humans and animals (Baranov, 2019; Yurchenko, Krivtsova, & Podolnaya, 2008). The popularity of this test is because it is fast, non-invasive, and economically viable, allows an intravital screening of the examined individuals an unlimited number of times, and does not require special equipment for cell culture or enhanced sterility.

An indicator of genetic disorders in interphase nuclei is not only the frequency of the micronuclei but also the sum of cytological disorders, such as binuclear cells, protrusions, and destructive changes in nuclei. Micronuclei are formed mainly from fragments of chromosomes lacking a centromere during the formation of chromosome aberrations or due to lagging at the anaphase stage of the total number of diverging chromosomes. During mitosis, this material enters one of the daughter cells and forms one or more micronuclei. They can also be formed by the whole chromosome as a result of the violation of the spindle of division (Kolmakova, Belik, Morgul, & Sevryukov, 2013).

Protrusions, like micronuclei, can be formed by fragments of chromosomes or due to

lagging when the fission spindle is broken by whole chromosomes, the nuclear membrane of which is connected to the membrane of the central nucleus. A broken egg protrusion looks like a micronucleus connected to the nucleus by a nucleoplasmic bridge. It is assumed that nuclear protrusion can also be formed by budding of the interphase nuclei (Sarto *et al.*, 1987).

Proliferation indicators are the presence in the sample of binuclear cells and nuclei with a circular notch (a groove that is equal to or partially shifted to one of the poles of the groove). This anomaly is likely to arise in the process of incomplete mitosis as a result of damage to the spindle of division (Holland *et al.*, 2008).

Indicators of nuclear destruction are the presence of cells with karyorrhexis, karyolysis, and apoptotic bodies. They are observed in diseases of accumulation, inflammation, as well as after exposure to chemicals and radiation (Holland *et al.*, 2008).

Determining the genetic status of the most vulnerable population – adolescents from 16 to 18 years old, living in different regions of the country according to environmental stress – will show the presence of cytological disorders at the cellular level, which can lead to various health problems in the future. Undoubtedly, under the conditions of scientific and technological progress on a global scale, there is a high probability of an increase in ecogenetic pathology, which requires strengthening the measures to prevent diseases caused by an unfavorable living environment due to the growing role of new pollution factors (Landrigan & Fuller, 2015). The research results will bring a new understanding of the problem of the deteriorating health of the younger generation according to the ecology of the living environment.

Hence, the purpose of this study is to show the influence of dominant environmental factors in distant regions of Kazakhstan on cytogenetic disorders in the bodies of the younger generation.

## 2. MATERIALS AND METHODS:

The study participants were schoolchildren living in cities and villages located 150-200 km from the Semipalatinsk Test Site and the Aral Sea region of Kazakhstan, 150-200 km from the Aral Sea. A total of 182 high school students aged 16 to 18 years were examined, of which 81 were schoolchildren living near the Semipalatinsk Test Site of the East Kazakhstan Region, and 101 were students living in the Aral Sea region of the Kyzylorda Region. At the time of the study, all

students were healthy. According to the requirements of the local ethics commission, informed consent was obtained from each participant and their parents. The cytogenetic studies carried out were comparative in nature, allowing a new understanding of the nature of their appearance, regardless of the type of dominant environmental load, and the long-term effects of the radioactive contamination or mineralization of the atmosphere and drinking water.

For an analysis of the cytogenetic smear preparations, samples of buccal epithelium were taken by scraping epithelial cells from the inner surface of the pupils' cheeks with a plastic spatula. Next, the epithelial cells were resuspended in 100 µl of phosphate buffer (AMRESCO) or saline, evenly distributed over the surface of the slide, and dried in air. Two preparations were prepared (right, left cheek) from each student. The preparations were stained with 10% Romanovsky–Giemsa solution for 10 min (Stefanović *et al.*, 2017).

The micronuclei frequency was calculated using a Zeiss Axioscop 40 microscope at a magnification of 16x10. Photo documentation of the most specific disorders of the analyzed epithelial cells was carried out. The cytogenetic analysis of the buccal epithelium was conducted for 1000 to 3000 cells in each sample. The frequency of cytogenetic disorders was calculated as a percentage per 100 cells analyzed. When conducting a cytogenetic examination, all violations of the structure of epithelial cells that differed from normal morphology were recorded. The data obtained were processed using Microsoft Office Excel software. To compare the average values, a student's t-test was conducted using the formula (Eq. 1):

$$t = \frac{M_1 - M_2}{\sqrt{\frac{m_1^2 + m_2^2}{2}}} \quad (\text{Eq. 1})$$

where  $M_1$  and  $M_2$  are the arithmetic means of the compared indicators, and  $m_1$  and  $m_2$  are the average errors of these indicators. The number of degrees of freedom was found according to the formula (Eq. 2):

$$F = (n_1 + n_2) - 2 \quad (\text{Eq. 2})$$

after which the student criterion was determined from the Table at a significance level at  $p \leq 0.01$ . (Chaliev & Ovcharov, 2007).

To examine the schoolchildren, permission was obtained from the Local Ethics Commission (LEC) of the Kazakh National Medical University, S.D. Asfendiyarova, extract from protocol No. 3 (80) of 02/27/2019.

### 3. RESULTS AND DISCUSSION:

The cytogenetic analysis of buccal epithelial cells of the oral cavities of students living in the Aral Sea region of Kazakhstan and near the Semipalatinsk Test Site of the East Kazakhstan Region showed the presence of epithelial cells containing a few micronuclei (m/i), cells with a protrusion of nuclear material, binuclear cells, and epithelial cells with apoptotic bodies and karyolysis. Figures 1 – 4, respectively, show images of normal epithelial cells and cells with various changes, namely with two nuclei, a protrusion of nuclear material, and epithelial cells with apoptotic bodies and karyolysis, as detected in the students.

When comparing the data of urban students in both regions, it was found that the frequency of cells with cytogenetic disorders in adolescents living in the city of Semey, located near (143 km) the Semipalatinsk Test Site, is 7 times higher than that of schoolchildren in the Aral Sea region (Table 1).

In rural schoolchildren living in settlements located 200 to 300 km from the Semipalatinsk Test Site, the frequency of cells with cytogenetic disorders was 1.6 times higher than in rural teenagers of the Aral Sea region living 200 km from the Aral Sea. In terms of proliferation, no significant differences were observed in both regions (Table 1). Based on the changes in the structure of the nucleus, it was found that urban schoolchildren living in the city of Semey (East Kazakhstan Region, Kazakhstan) had a 20 times higher frequency of nuclear destruction than urban pupils in the Aral Sea region. However, in rural schoolchildren living near the nuclear test site (East Kazakhstan Region, Kazakhstan), the frequency of nuclear destruction was 4 times lower than that of rural students in the Aral Sea region (Table 1).

In general, adolescents in both studied regions showed a high level of cytogenetic changes. The maximum level of micronucleus frequency was found in 90% of the examined adolescents, 2-3 nuclei were found in the genetic material of 54% of the examined schoolchildren, and protrusions were found in 41% of students, regardless of the place of residence and environmental load. Nevertheless, in the students from Semey, located near the Semipalatinsk Test Site, the cytogenetic changes associated with nuclear destruction (karyorrhexis, karyolysis, and apoptosis) were found to be significantly higher than in the adolescents in the Aral Sea region. The presence of a high frequency of such violations in

the younger generation indicates that the long-term effect of environmental pollution by radioactive contamination products has been preserved despite the fact that the nuclear test site has been closed since 1991.

It is known that buccal cells have a limited ability to recover DNA compared to peripheral blood lymphocytes and, therefore, can more accurately reflect the age-related event of genomic instability in epithelial tissue (Grewal, Jindal, & Chauhan, 2013; Ladnova, Istomin, Kurochitskaya, & Silyutina, 2016). Being in direct contact with inhaled and absorbed genotoxic agents and metabolites of various chemicals, epithelial tissues are the first to express the genotoxic effects of these agents. The frequency of occurrence of micronuclei reflects the destruction of chromosomes under the action of adverse factors long before the development of clinical symptoms of pathological disorders of the body's functions (Grewal *et al.*, 2013; Podrimaj-Bytyqi *et al.*, 2018; Thomas *et al.*, 2009; Weng & Morimoto, 2009).

As a result of a cytogenetic analysis of oral epithelial cells, various cytogenetic disorders were revealed in two-thirds of the examined adolescents from 16 to 18 years old. The most significant percentage of violations associated with the presence of micronuclei was detected in urban students living 130 km from the former Semipalatinsk Nuclear Test Site. The data obtained are consistent with the high incidence of disease among adolescents in this region, as cited by official sources. The official statistical data for the teenage population of the East Kazakhstan Region of Kazakhstan for the period 2010-2017 showed a high incidence of neoplasms as well as a cardiovascular, respiratory and nervous system, and congenital anomalies at a rate 1.5-2 times higher than the average national level (Ministry of Health of the Republic of Kazakhstan, 2011, 2017, 2018).

When comparing the results of the study of buccal epithelium samples of urban and rural students of the Aral Sea region (Kyzylorda Region, Kazakhstan), the likelihood of developing cytogenetic disorders in rural adolescents, such as micronuclei, proliferation and nuclear destruction, including karyorrhexis, karyolysis, and apoptosis, which also indicates a negative effect, is revealed concerning the impact of the ecology of the region of residence on the health of the younger generation. This is confirmed by the official statistics for the period 2010-2017 and by the total morbidity of adolescents aged 15 to 17 years in the Kyzylorda Region, which shows that the number

of sick adolescents is 45% more in rural areas (10509.4 cases) than in the city (7218.0 cases). Moreover, over the past seven years, the incidence of adolescent diseases of the blood and blood-forming organs, as well as immune disorders and iron deficiency anemia, has remained significantly high, exceeding the national average by 2 times (in 2017, 3,792.2 cases in the Republic of Kazakhstan against 7976.8 cases in the Kyzylorda Region per 100 thousand teenagers) (Ministry of Health of the Republic of Kazakhstan, 2017).

The changes in the chromosomal material of the cells of the body of the younger generation shown in this work reflect a whole set of cytogenetic changes up to the destruction of the cell nucleus, regardless of the type of pathological environmental factor. Adolescents living in places located near the former Semipalatinsk Test Site, as well as the adolescent population of the Aral Sea region, suffer from pollution and drought in the region due to the drying out of the Aral Sea, whereby identical changes in cytogenetic indices with slight deviations in one direction or another were revealed. Considering that the main period of active pollution of the ecology of the regions where the adolescents lived was in the 1970-80s (Stepanov, 2016), the revealed changes at the chromosomal level show the long-term negative effect of environmental pollution on the health of the younger generation (UNESCO, 2013).

Currently, the acceleration of technological progress is creating more zones of ecological disadvantage, which is increasing the incidence of disease among the child population. This is not only occurring in the present but will also, as our study shows, cause cytogenetic changes in the cells of the bodies of future generations. In different countries of the world, the genetic vulnerability of populations to various environmental challenges has been shown (Panico *et al.*, 2020; Zani *et al.*, 2020). Mexican researchers investigated and showed the effect of gasoline vapors contained in exhaust gases on the human genome. They revealed cytogenetic disorders such as micronucleus frequency, karyolysis, karyorrhexis, and binuclear cells in the buccal epithelium, similar to our results. The authors suggest that this can cause carcinogenic diseases (Martinez-Valenzuela *et al.*, 2017). Genomic instability in the buccal epithelial cells of children living in one of the contaminated regions of Brazil has also been shown. The authors indicated a high level of cytogenetic disorders, also similar to our data, in children under the influence of the abnormal ecology of the region,

namely the pollution of water resources (Alpire, Cardoso, Seabra Pereira, & Ribeiro, 2019). Indian researchers, assessing the health of children, also indicated genetic damage, such as damage to telomere length, micronuclei, and urothelial cells in samples of the buccal epithelium, as a result of drinking water from underground sources with increased content of heavy metals that are especially dangerous for health, such as arsenic (Chatterjee *et al.*, 2018). In Russia, in the Altai Territory, which is 500 km or more distant from the Semipalatinsk test site, an increased level of cytogenetic abnormalities and incidence of adolescent endocrine diseases and congenital anomalies has been maintained for 40 years (Kolyado, Plugin, & Konovalov, 2017; Muldagaliev & Konovalov, 2018). Increasingly, they write about the impact of climate change in Central Asia on the health and gene pool of the population (Danielyan, Nazaretyan, Kosyan, & Nersisyan, 2017; Montgomery, 2016; Mullerson, 2014).

As can be seen from the literature, the presented research results are consistent with the data of various authors on a global scale, thereby introducing a new insight into the problems of the increased incidence of disease among the child population in regions where the peak of environmental problems was observed 40-50 years ago. The revealed cytogenetic disorders in the younger generation highlight the need to reduce the environmental burden in all regions to preserve the health of children, for both current and future generations.

#### 4. CONCLUSIONS:

Ecological dysfunction of the environment has a distant negative effect on the health of the younger generation and contributes to the development of cytogenetic disorders at the cellular level:

1. The maximum level of cytogenetic disorders associated with increased micronuclei and proliferation of nuclei in cells was detected in students living 150-200 km from the Semipalatinsk nuclear test site. The data are consistent with official data for 2010-2018 on a high incidence of adolescents in this region with diseases of the cardiovascular, respiratory and nervous systems, neoplasms and congenital anomalies exceeding 1.5-2.0 times the national average.

2. An extensive spectrum of cytogenetic disorders was detected in the overwhelming majority of the Aral Sea teenagers living 150-200 km from the dried Aral Sea, the territory of which

is characterized by desertification and significant salinization of the soil and remaining water. The micronuclei, the presence of 2-3 micronuclei, the proliferation of the nucleus and the destruction of the cell nucleus in the form of karyorrhexis, karyolysis and apoptosis were revealed in the buccal epithelium of the adolescent population, which indicates the continuing negative effect of the dried Aral Sea on the genetic material of the young generation of this region.

The presented data on cytogenetic changes in children born much later than peak environmental pollution emphasize the need for constant monitoring of their health and assessment of their genetic status, since environmental and human health issues are interrelated and are one of the urgent problems of our time. Given that the current study is preliminary, further analysis with a wider selection of children from different regions of the country is of scientific interest and opens up prospects for the future.

#### 5. ACKNOWLEDGEMENTS:

The study was funded by the Science Committee of the Ministry of Education and Science of the Republic of Kazakhstan as part of grant No. AR05132033.

**RESUMO**

A dopagem química é uma rota promissora para projetar e controlar as propriedades eletrônicas de nanofibras de grafeno em zigue-zague (ZGNR). Utilizando os primeiros princípios dos cálculos da teoria funcional da densidade (DFT), no B3LYP / 6-31G, implementado no software Gaussian 09, várias propriedades, como a estrutura geométrica, o espectro de infravermelho DOS, HOMO, LUMO e o gap de energia do ZGNR foram investigadas com vários locais e concentrações de fósforo (P). Observou-se que o ZGNR pode ser convertido da dimensão linear para a fractal usando impurezas de fósforo (P). Também se destaca a árvore binária fractal das estruturas ZGNR e P-ZGNR. Os resultados demonstraram que a diferença de energia possui valores diferentes, localizados nessa faixa de 0,51eV a 1,158 eV para estruturas ZGNR e P-ZGNR intocadas. Essa faixa de gap de energia é variável de acordo com o uso de GNRs em qualquer aparelho. Então, o P-ZGNR tem comportamento semicondutor. Além disso, não há números de onda imaginários no espectro vibracional avaliado, confirmando que o modelo corresponde à energia mínima. Então, esses resultados fazem com que o P-ZGNR possa ser utilizado em várias aplicações, devido a essa estrutura ter se tornado mais estável e com menor reatividade.

**Palavras-chave:** *Nanofibras de grafeno, diferença de energia, Densidade de estado, espectros de infravermelho.***ABSTRACT**

Chemical doping is a promising route to engineering and controlling the electronic properties of the zigzag graphene nanoribbon (ZGNR). By using the first-principles of the density functional theory (DFT) calculations at the B3LYP/ 6-31G, which implemented in the Gaussian 09 software, various properties, such as the geometrical structure, DOS, HOMO, LUMO infrared spectra, and energy gap of the ZGNR, were investigated with various sites and concentrations of the phosphorus (P). It was observed that the ZGNR could be converted from linear to fractal dimension by using phosphorus (P) impurities. Also, the fractal binary tree of the ZGNR and P-ZGNR structures is a highlight. The results demonstrated that the energy gap has different values, which located at this range from 0.51eV to 1.158 eV for pristine ZGNR and P-ZGNR structures. This range of energy gap is variable according to the use of GNRs in any apparatus. Then, the P-ZGNR has semiconductor behavior. Moreover, there are no imaginary wavenumbers on the evaluated vibrational spectrum confirms that the model corresponds to minimum energy. Then, these results make P-ZGNR can be utilized in various applications due to this structure became more stable and lower reactivity.

**Keywords:** *Graphene Nanoribbon, energy gap, Density of State, Infrared spectra.*

## 1. INTRODUCTION:

Graphene nanoribbon (GNR) may be a sheet of graphite (monolayer) comprising of atoms  $sp^2$  hybridized C making a daily honeycomb (hexagonal) lattice. GNR has attracted considerable importance within the industry and research community thanks to its outstanding properties like structural, electronic, and optical. Recently, there has been outsized importance towards the realization, and studying of nanoribbon graphene supported devices of electronic design through the accurate structure of electronic tailoring that exploiting the electrical field effect and other fields of application as strain. In other words, the GNR has stimulated enormous outburst of experiment and theoretic fields an investigation (Aliofkhazraei *et al.* 2016); (Moghaddam *et al.* 2011); (Abbott's 2007); (Sahoo and Dutta 2012); (Banerjee and Sahoo 2013); (Bryan 2013).

Many reports (theoretical) proposed an electronic property (band structure) must appear that's presumed to account upon the shape and width (Oliveira Jr *et al.* 2015), additionally to the precise orientation for crystallographic of nanoribbon (Morozov *et al.* 2005); (Ezawa 2006); (Brey and Fertig 2006); (Shemella *et al.* 2007); (Son, Cohen, and Louie 2006a). GNRs with edges of shaped of zigzag are assumed to possess gaps of the direct band, where the gap lowers with width increasing, while edges of armchair-shape are often either semiconducting or metallic counting at widths (Nakada *et al.* 1996); (Wakabayashi *et al.* 1999); (Celis *et al.* 2016); (Neto *et al.* 2009); (Geim and Novoselov 2010); (Son, Cohen, and Louie 2006b); (Ajeel, Mohammed, and Khudhair 2019). One is aware that the stability of Hydrogen terminated GNR (Okada 2008); (Wassmann *et al.* 2008).

Benoit Mandelbrot (Mohammed Lateef Jabbar 2015); (Vass 2014); (Jebbar 2007); (Mohammed L Jabbar 2017) suggested the existence of geometries, referred to as geometry. A natural sort of fractal tree is represented by a binary fractal tree (BFT). Four factors specify a binary fractal tree ( $\theta_1$ ,  $\theta_2$ ,  $r_1$ , and  $r_2$ ). Where, the primary two factors (belong the angle) are the branching angles  $\theta_1$  and  $\theta_2$ , which may take any real values between  $0^\circ$  and  $360^\circ$  while the last two factors are the scaling ratios  $r_1$  and  $r_2$ , which may take any real values between 0 and 1 (Taylor 2005); (Pons 2013).

An intuitive explanation of a binary fractal

tree is as follows. Every tree features a trunk, which may be a closed vertical line segment of unit length. This trunk divides into two new branches at the highest. The primary branch has length  $r_1$  and makes of  $\theta_1$  angle with the affine trunk hull, and therefore the second branch has length  $r_2$  and makes of  $\theta_2$  angle with the affine trunk hull. Each of those two branches procedures the trunk of a sub-tree, i.e., it splits into two more branches, following an equivalent method. BFT is that the object obtained by applying the branching process to Infinitum (Taylor 2005); (Mandelbrot and Frame 1999); (Koch and Holthausen 2015) (Baughman, Zakhidov, and De Heer 2002) (Pons 2013). The density functional methods supply a strong instrument in quantum physics and computational nanoscience of atoms, (Parr 1980) molecules and other finite structures (Martin and Martin 2004). It proposes the density function rather than the wave function to explain the quantum systems (Wysokiński, Kuduk-Jaworska, and Michalska 2006). Born interpretation is one among methods that represent the theoretical basis of density functional theory (Tozer and De Proft 2005). It offers a chic formulation of the N electron system and computational efficiency (Young 2004). Electron density plays an important role in molecular structure, electrostatic potential, and contours (Koch and Holthausen 2015) (Koch and Holthausen 2015). Density functional theory (DFT) is additionally an approximation for the outline of the properties of the bottom state of insulators, metals, and semiconductors. The base state is unequivocally defined by the electron density (Mohammed L Jabbar 2018); (H Muzel, Alwan, and Jabbar 2017).

The main purpose of this paper was to study the binary fractal trees structure (with a scaling ratio  $r=r_1=r_2=1$  to make some structures of zigzag graphene nanoribbon (ZGNRs) doping by phosphorus atoms), and electronic properties of the graphene systems. Based on the first-principles of the density functional theory calculations, frontier orbital (highest occupied molecular orbital, HOMO, and lowest unoccupied molecular orbital, LUMO) distributions, the energy gaps, density of state and infrared spectra have been investigated.

## 2. MATERIALS AND METHODS:

Herein are hydrocarbons chains of aromatic polycyclic (PAHs) that are occupied as ZGNRs models of finite-size. The treated ZGNRs contain edges of zigzag shape on each side with passivation hydrogen to decrease the boundary

effects (Figure 1). The GNR may be a rectangular  $[n,m]$  with width  $m=4$  (in direction of armchair) and length  $n=6$  (in direction of zigzag).

## 2.1. Details of computation

All ZGNRs computations were carried out utilizing the method of DFT as applied within the Gaussian 09W software (Frisch *et al.* 2009). B3LYP (Stephens *et al.* 1994), as a functional hybrid that informs the exchange of Becke (Becke 1992) and correlation of Lee, Yang, and Parr's (Lee, Yang, and Parr 1988) the 3-21G (or 6-31G) means set of basis (Petersson and Al-Laham 1991), were utilized for the computation of quantum-chemical (H Muzel, Alwan, and Jabbar 2017); (Zandler and D'Souza 2006); (Rad 2016); (Yoosefian, Raissi, and Mola 2015). Before energy calculations for pristine ZGNR and with addition different atoms levels of P, whole systems are relaxed. This process is named geometry optimization. The GNR electronic characteristics such as DOS of analysis, energies of molecular highest occupied orbital (HOMO), molecular energies of lowest unoccupied orbital (LUMO), and gaps of energy (the eigenvalues difference the of the maximum valence band and therefore the band of minimum conduction or mathematically through express  $E_g = E_{LUMO} - E_{HOMO}$ ) are theoretically investigated along few impurities structures P by using fractal binary tree method as novel mathematically model for doping.

## 3. RESULTS AND DISCUSSION:

As a primary task, the researchers started by building a pristine, a ZGNR. It consists of 48 atoms. GNR rectangular  $[4, 6]$  (rectangular  $[n, m]$  with width equally ( $m = 4$  atoms) (in the armchair direction) and length equally ( $n = 6$  atoms)) of width adequate to 4 (in the trend of an armchair) and length appropriate to 6 (in the trend of zigzag), is GNR designated  $[4, 6]$ . The ZGNRs treated contain edges of a zigzag for a single side along with the passivation of Hydrogen to minimize the effects of the boundary. Method of DFT was used to optimize the structure geometrically along with the B3LYP functional of hybrid. The structure of the pure GNR  $[4, 6]$ , as elucidated in Figure 2, is consistent with GNRs are nowadays illustrious: their characters of electronic predicted to be considered upon the shape and width, additionally to the precise crystallographic orientation of the nanoribbon. However, it is not possible to observe the visible deformation of pure GNRs along its zigzag direction.

The model BFT can be applied in the doping process to get a new structure. An intuitive description of a BFT is as follows. Each tree features a trunk, which may be a closed vertical line segment of unit length (Figure 3a). This trunk divides into two new branches at the highest. One branch has length  $r_1$  and yields  $\theta_1$  angle with affine trunk hull, and therefore other branch has length  $r_2$  and yields  $\theta_2$  angle with affine trunk hull as illustrated in Figure 3b. Those 2 branches yields subtree trunk as elucidated in Figure 3c, i.e., it splits into two more branches, following an equivalent method., a pristine GNR was then doped with different impurities of phosphorus atom ( $P=2, 4, 8$ ). This addition of impurities obeyed to mathematically model. It's been wont to create nanostructures involving phosphorus element, theoretically, by using the geometry to urge a replacement structure to replace some carbon atoms within the pristine structure by the number of phosphorus atoms to offer the model binary fractal tree. Also, the models are geometrically optimized and need final arrangements (Figures 3 and 4).

As the fractal binary tree retains branching and splitting from 0 into 1 into 2 and so on., the binary tree is doing so, during this case, in base two and a scaling ratio  $r=r_1=r_2=1$ . The primary step of binary fractal tree does not have any value of angle with vertical line in other word, the angle value will adequate to zero. The second step branch trunk has one angle with a vertical line, while the third step has two angles on each side (Table 1).

Current surface is often expressed by high orbital's molecular occupation (HOMO) and low orbital's molecular occupation (LUMO). The abbreviations HOMO and LUMO occasionally ask the frontier orbitals in frontier molecular orbital theory. Figure 5 appears schematic HOMO, LUMO surfaces for pure GNR  $[4,6]$ , and GNR with P. The resulting orbitals could also be interpreted consistent with a molecular orbital theory, which considers the orbitals of the molecule because of the combination of linearity to the orbitals of molecule. The green color in figure 5 mentions positive a part of the function of the wave, whereas red color mentions the negative a part of the function of the wave. The energy gap may be a vital property in solids because it allows the prediction of the fabric, whether it's conductor or insulator or semiconductor. The bandgap is defined because of the difference in energy between the upper region of the valence band edge (VBE) and,

therefore, the lower region of conduction band edge (CBE).

Table 2 demonstrates the values of LUMO, HOMO, and energy gap for GNR and GNR with impurities (P=2, 4, and 8), respectively. During this work, the worth of the energy gap is calculated for pristine GNR following others obtained results (Son, Cohen, and Louie 2006a). Here energy values gap for both GNR and GNR with dopants performed by Gaussian 09 package. One note that the structures have different values of energy gap thanks to the various numbers and positions of dopants. Whereas, the electronic properties of GNR are quite different due to these different interfacial Interactions.

Figure 5 demonstrates that states density (DOS) versus energy according to the chemical structure of the material; naturally when the chemical structure is modified, at least, in theory, the DOS distribution should change. Generally, those impurities are called dopants, so the chemical composition changes by doping. The change within the energy distribution of the allowed states cannot have a general rule such as the bandgap will increase after the introduction of impurities from phosphorus.

The infrared spectral range is extensive, approximately from 12800 to 10  $\text{cm}^{-1}$  spectral region. In the IR spectrum, a molecule to be absorbed by the moment of the molecules should be expected to vary as a result of vibration and rotation frequencies. There are two sorts of stretching variations. The primary type is named symmetric stretching, which occurs when the vibration of atoms of equivalency occurred within an identical phase. The opposite last type is called stretching of asymmetric, which takes place when vibrations of bonds occur in different phases. IR spectrum shows information about the structure of a molecule. The frequencies of harmonic vibration are studied for pure P-GNRs and GNR. Figure 6a shows the peaks shape for pure GNR, while figures 6b – 6d elucidate that there is a peak replacement; a single peak denotes the bond between 2 atoms neighboring to each other. Figure 6a demonstrates some peaks in the 800-900  $\text{cm}^{-1}$  region (c-c single bond - aromatic atoms), whereas the peaks in 1200 - 1550  $\text{cm}^{-1}$  region are the (c=c double bond - aromatic atoms). The obtained results are following the experimental results (Dykstra *et al.* 2017). New bonds inform new modes of specific numbers wave, whereas spectra of infrared are effected by coordinates of geometry and topological characters. Figure 6 shows C-P and P-P bond, which is cause to point

out a replacement peak. These new peaks show thanks to strange atoms. Then the structure will become asymmetric.

#### 4. CONCLUSIONS:

The structures were extremely useful in making up apply devices because they need hetero-junction of band gap (the ability to fabricate P- and n-type regions is required). The calculations demonstrated that this work might be an example to use the mathematical model to make nanostructures involving phosphorus element by using the fractal geometry method to exchange some atoms in the pristine structure by phosphorus atoms. The model binary fractal tree can apply in doping process to get a new structure. The non-existence of imaginary wavenumbers on the evaluated vibrational spectrum confirms that the model corresponds to minimum energy.

**RESUMO**

No sistema de ensino superior, o ensino a distância usando cursos eletrônicos de educação está se tornando a maneira mais relevante e amplamente exigida de aprendizado. Isso se deve principalmente ao rápido processo mundial de digitalização da educação. Além disso, em conexão com a transição para um sistema educacional de dois níveis, o número de horas no currículo dedicado ao trabalho independente dos alunos aumentou significativamente. Essas tecnologias são uma boa ferramenta para organizar a independência cognitiva de um aluno. As vantagens são a capacidade de estudar a qualquer momento, em qualquer lugar, a capacidade de aprender no próprio ritmo e a capacidade de aprender sem interromper o trabalho. Por outro lado, existem algumas deficiências, como o problema de identificação do usuário e a necessidade de o aluno ter uma forte motivação. Este estudo teve como objetivo mostrar uma das opções para organizar o trabalho independente dos alunos no exemplo do curso educacional eletrônico "Matemática e fundamentos do processamento de informações matemáticas", criado com base no sistema LMS MOODLE. Participaram do experimento 30 estudantes de dois grupos acadêmicos (15 pessoas cada), com idades entre 16 e 17 anos, estudando na Universidade Federal do Instituto Elabuga de Kazan (Volga). Um dos grupos dominou a disciplina "Matemática e Fundamentos do Processamento de Informações Matemáticas" na forma tradicional, o outro grupo - na forma remota, usando o curso educacional eletrônico desenvolvido pelos autores. Depois de estudar o curso em ambos os grupos, foram realizados trabalhos de verificação e uma pesquisa. O processamento dos resultados do trabalho de controle usando métodos estatísticos possibilitou avaliar quanto o sucesso dos alunos em matemática depende da escolha da forma de treinamento. Os resultados da pesquisa permitiram aos autores formular maneiras de melhorar a qualidade da matemática do ensino a distância usando um curso educacional eletrônico.

**ABSTRACT**

In the higher education system, distance learning using electronic educational courses is becoming the most relevant and widely demanded way of learning. This is primarily due to the rapidly developing

worldwide process of digitalization of education. Besides, in connection with the transition to a two-level education system, the number of hours in the curriculum devoted to students' independent work has significantly increased. These technologies are a useful tool for organizing a student's cognitive independence. The advantages are the ability to study at any convenient time, anywhere, the ability to learn at one's own pace, and the ability to learn without interrupting work. On the other hand, there are some shortcomings, such as the problem of user identification and the need for the student to have strong motivation. This study aimed to show one of the options for organizing students' independent work on the example of the electronic educational course "Mathematics and Fundamentals of Mathematical Information Processing", created on the basis of the LMS MOODLE system. The experiment was attended by 30 students from two academic groups (15 people each) aged 16 to 17, studying at the Elabuga Institute of Kazan (Volga) Federal University. One of the groups mastered the discipline "Mathematics and Fundamentals of Mathematical Information Processing" in the traditional form, the other group - in the remote form using the electronic educational course developed by the authors. After studying the course in both groups, verification work and a survey were conducted. Processing the results of the control work using statistical methods made it possible to assess how much the success of students in mathematics depends on the choice of the form of training. The survey results allowed the authors to formulate ways to improve the quality of distance learning mathematics using an electronic educational course.

## АННОТАЦИЯ

В системе высшего образования дистанционное обучение с помощью электронных образовательных курсов становится наиболее актуальным и широко востребованным способом обучения. Это связано, в первую очередь, со стремительно развивающимся во всем мире процессом цифровизации образования. Кроме того, в связи с переходом на двухуровневую систему образования значительно возросло количество часов в учебном плане, отводимых на самостоятельную работу студента. Эти технологии являются хорошим инструментом для организации познавательной самостоятельности студента. Преимущества - способность учиться в любое удобное время и в любом месте, способность учиться в своем собственном темпе и способность учиться, не прерывая работу. С другой стороны, есть некоторые недостатки, такие как проблема идентификации пользователя и потребность в сильной мотивации учащегося. Целью данного исследования было показать один из вариантов организации самостоятельной работы студентов на примере электронного учебного курса «Математика и основы математической обработки информации», созданного на основе системы LMS MOODLE. В эксперименте приняли участие 30 студентов из двух академических групп (по 15 человек в каждой) в возрасте от 16 до 17 лет, обучающихся в Елабужском институте Казанского (Приволжского) федерального университета. Одна из групп освоила дисциплину «Математика и основы математической обработки информации» в традиционной форме, другая группа - в дистанционной форме с использованием электронного учебного курса, разработанного авторами. После изучения курса в обеих группах были проведены проверочные работы и опрос. Обработка результатов контрольной работы с использованием статистических методов позволила оценить, насколько успехи учащихся по математике зависят от выбора формы обучения. Результаты опроса позволили авторам сформулировать способы повышения качества дистанционного обучения математике с помощью электронного учебного курса.

**Ключевые слова:** *математика, дистанционные образовательные технологии, обработка информации, оценка эффективности.*

## 1. INTRODUCTION:

In connection with the transition to a two-level education system, the number of hours in the curriculum devoted to students' independent work has significantly increased. For its active organization, distance educational technologies are widely used. Also, these technologies play an essential role in the rapidly developing worldwide digitalization of education (Schmidt & Tang, 2020).

Remote educational technologies are understood to be technologies that are implemented primarily with the use of information and telecommunication networks with the indirect interaction of students and teachers (Kuderova *et al.*, 2019). There are various ways of organizing distance learning: using electronic educational resources (Anisimova & Krasnova, 2015; Akhmetshin *et al.*, 2019), digital educational resources, massive open online courses (MOOC), offering extensive interactive participation and open access through the

Internet (Kaplan & Haenlein, 2016).

Due to the intensification of the digitalization of education worldwide, not only colleges and universities but also schools pay attention to various ways of distance learning (Dawson *et al.*, 2009; Fuller, Vician, & Brown, 2006; Guri-Rosenblit, 2016; Kearsley, 2000). Online learning is gaining popularity every day, significantly expanding the educational space (Beese, 2014; Soekartawi, & Librero, 2002) and allowing students to independently study various educational programs (Aktaruzzaman & Plunkett, 2016).

In addition to the fact that distance educational technologies are an excellent tool for organizing a student's cognitive independence, there are many other advantages of their use.

Firstly, the opportunity to learn at a convenient time. Indeed, studying remotely, a student has the opportunity to build his or her own individual training schedule, determine when and how much time to spend studying a particular material (Nguyen, 2015).

Secondly, the ability to learn at one's own pace (Thoms & Eryilmaz, 2014). In the traditional form of training, the teacher, as a rule, focuses on a particular group of students – average performers. In the case of distance learning, the learning process takes place at a pace convenient for the student. He or she can always return to the study of more complex topics, re-examine the lecture material, ask questions to the teacher online.

Thirdly, the ability to learn in a convenient place (Bachmaier, 2011; So & Brush, 2008). With the remote form of training, a student can study without leaving home, which is especially important for people with disabilities, for people with small children.

Also, other significant advantages are the opportunity to learn without interrupting work; availability of training materials (with the remote form of training, all educational material, as a rule, is posted on the course);

Non less critical, it has to be considered the possibility of implementing an individual approach (Korableva *et al.*, 2019 a, b). In the traditional form of teaching, it is quite difficult for a teacher to pay attention to each student to adapt to the pace of each of them. In the case of the remote form, students have the opportunity to receive answers to their questions in a mode convenient for them.

Besides, the convenience for the teacher. With distance learning, the teacher can pay attention to each student, has the opportunity to observe the learning process, even while on a business trip. Although, at the same time, the load on the teacher increases, so it is necessary to provide the teacher with appropriate financial support, reduce his or her workload (Meyer & Barefield, 2010).

However, there are several disadvantages of this form of training, which make teachers doubt the effectiveness of the use of distance technologies in the educational process. Indeed, in the modern educational environment, the success of the introduction of distance learning largely depends on the perception of teachers.

One of the shortcomings is the need for a student to have strong motivation. Since the student learns all the material on a distance-learning basis, this requires good willpower, self-discipline, perseverance, and responsibility (Chow & Croxton, 2017).

Another topic is the bias toward theoretical knowledge. Indeed, with the remote form of training, it is rather difficult to carry out the study of disciplines that require a large number of practical classes. This is especially true for the disciplines of the natural science cycle.

The problem of monitoring the learning process is also relevant. Unfortunately, in most cases with distance learning, it is impossible to check how honestly the student is concerned with completing assignments and whether he or she performs them him/herself. Therefore, the final form of control should be carried out in the audience.

The impossibility of developing such personal qualities as sociability, teamwork, oratorical qualities (Joksimović *et al.*, 2015; Keller *et al.*, 2017; Liaw, Huang, & Chen, 2007; Xiao, 2018) might put this tool in doubt. At the same time, for people experiencing difficulties with socialization in the real world, distance learning is a definite plus, allowing one to get an education in a comfortable environment (Sazmandasfaranjan *et al.*, 2013)

Insufficient technical equipment of the teacher's and (or) student's workplace (Anderson & Dron, 2011; Hung, 2016; Rogerson-Revell, 2015) can also be faced as a disadvantage.

It is also important to remember the students' poor computer literacy (Hatlevik *et al.*,

2018; Hoffman & Vance, 2005) and insufficient degree of mastering the material compared to traditional training (Kirtman, 2009). For example, the number of students taking at least one online course increased in the USA in 2013 to 6.7 million people (Allen & Seaman, 2013). At the same time, the Pew Research Center found that, although many college leaders in America said their institutions offered online courses, only 50% agreed that these courses were at the same level as traditional study classes (Parker *et al.*, 2011).

There are also institutional and financial problems that hinder the spread of distance technologies in the educational environment. The lack of qualified teachers (Baran *et al.*, 2011), weak government support (Piña, 2010), unequal competitive conditions (Drori, 2015; Zawacki-Richter & Anderson, 2014). Even in an academic environment, such a concept as "brand" is crucial. Therefore, large universities will have a more significant competitive advantage, positioning themselves as experts in creating educational materials of the required quality. They will also be more competitive because of the economic benefits of the number of students enrolling in their courses, as large universities have more opportunities to expand the audience of their courses through, for example, opening branches and representative offices in the regions. However, in turn, this forces regional universities to focus on more innovative teaching principles.

Thus, distance learning is a rapidly developing field in the field of education, including higher education (Reese, 2015). Distance education is developing per the goals set to increase the power, speed, and accessibility of educational technologies (Conde *et al.*, 2014; Shannon & Rice, 2017).

However, despite the advantages of distance learning, there are obstacles of a personal, institutional, and financial nature for the holistic implementation of the distance learning system in the educational process (Leontyeva, 2018).

Therefore, this study aimed to show one of the options for organizing students' cognitive activity that allows students to organize their independent work as efficiently as possible (by the example of the distance course "Mathematics and Fundamentals of Mathematical Information Processing," created based on the LMS MOODLE system), to evaluate the effectiveness of the use of distance learning technologies in the study of

mathematics and formulate possible ways to improve the quality of distance learning mathematics using an electronic educational course (based on statistical data collected in the process of students' work on the indicated course).

## 2. MATERIALS AND METHODS:

First, the authors briefly describe the structure of the course "Mathematics and Fundamentals of Mathematical Information Processing," created based on the LMS MOODLE system at the Elabuga Institute (branch) of the Kazan (Volga) Federal University (KFU) and posted on the KFU website for distance education (edu.kpfu.ru), disclose the algorithm for working with it, and then reveal the essence of the pedagogical experiment conducted by the author of the article to evaluate the effectiveness of the use of distance learning technologies in the study of higher mathematics at a university.

This educational distance learning course consists of the following topics (sections):

1. The primary means of presenting information in mathematics and their use in the pedagogical activity.
2. Elements of set theory. Counts. Functions.
3. Elements of probability theory.
4. Aspects of mathematical statistics.

Each section has the following structure (see Table 1):

**Table 1. Section Structure**

| <b>№</b> | <b>Components</b>  |
|----------|--|
| 1.       | Methodical recommendations to the student on the study of the topic. |
| 2.       | Lecture material.  |
| 3.       | Questions for self-control.  |
| 4.       | Test.  |
| 5.       | Verification work.   |
| 6.       | List of references.  |
| 7.       | Glossary.  |
| 8.       | Forum.   |

The content of the course is entirely consistent with the work program of the discipline.

The study of each section should begin by reading the guidelines (see Table 2), which

allow the student to build an algorithm for his work on the topic.

Each section includes lecture notes and self-examination questions (see Table 3). After studying the lecture material, the student proceeds to questions. Questions for self-control allow the student to evaluate the success of mastering the studied material independently. If difficulties arise with the answers to them, the student can return to studying the part of the lecture material that caused the challenges. Next, the student proceeds to test (see Table 4), the results of which demonstrate the degree to which the student has mastered this material and the possibility of moving to the study of a new section. Each test contains from 5 to 10 questions. The correct answer to one question is estimated at one point. To proceed to the next step (performing verification work), it is necessary that the student have at least 50% of the correct answers. As noted above, one of the features of LMS MOODLE is the ability to customize the course so that students get access to subsequent classes only after completing previous tasks. Therefore, it is possible to open for students' access to following forms of control only after completing the previous form for a satisfactory assessment. Testing can also be repeated if the initial result does not meet the requirements established by the teacher (these attempts are visible to the teacher from his/her personal account). The final form of control for each section (except section 1, which is primarily theoretical, and involves only the execution of the test) is the verification work (typical tasks for each topic can be seen in table. 5). The completed verification work is sent to the teacher for evaluation. Based on these forms of control, an assessment is made.

After studying all the sections, it is necessary to pass the final test, the questions (tasks) of which cover all the lecture and practical material on the course. The ultimate test consists of 30 questions (see Table 4). It includes questions from all the tests that are in sections 1-4.

Each section also includes a list of references, which can be useful in the case of questions in the process of studying the material. The student can also ask a question directly to the teacher on the course using interactive forms of communication integrated into the LMS MOODLE system (forum, chat), and the student can find the basic definitions and terms encountered in the process of studying the discipline in the glossary.

As noted above, one of the drawbacks of distance learning is the fact that it is impossible to evaluate how honestly one or another student completes assignments fully, it is impossible to verify whether he or she independently completed the proposed appointments. Therefore, the course ends with a final verification work, which is conducted in the audience and includes tasks from each topic of the course (see Table 5).

The study involved 30 students aged 16 to 17 years of first year at the Faculty of History and Philology of the Elabuga Institute of Kazan (Volga Region) Federal University. Among them were 26.67 percent of boys (8) and 73.33 percent of girls (22).

The experiment was conducted from September 2018 to December 2018.

At the beginning of the 1st semester (the 2018-2019 academic year), two groups of students were selected studying in the direction of 44.03.05 – Pedagogical Education (with two training profiles). The profile of the preparation of group No. 1 is the Russian Language and Literature, that of group No. 2 is History and Social Studies. The first group mastered the discipline "Mathematics and Fundamentals of Mathematical Information Processing" in remote form using the electronic educational course described above, the second - in the traditional style.

Since distance learning is currently very relevant, it is fully implemented at the Yelabuga Institute. Each university teacher develops electronic training courses that are widely used in teaching. Students subscribe to these courses without fail and undergo training under strict supervision.

The written permissions of the subjects to use their personal data allowed us to process their exam results, verification work, and survey.

In each group, 15 students were selected (in the first group there were 12 girls, 3 boys, in the second - 10 girls, 5 boys) with the following scores for the exam in mathematics (basic level):

Group No. 1 – 11, 12, 14, 12, 15, 16, 15, 16, 14, 16, 17, 16, 13, 14, 12.

Group No. 2 – 12, 11, 16, 14, 16, 14, 16, 14, 11, 15, 16, 17, 12, 13, 15.

Students were selected in such a way that their math exam results were not significantly different from each other.

First, it is necessary to find out whether it is advisable to experiment with these students. To do this, it is necessary to find the coefficient of variation. In this case, quantitative data (exam results) will be interpreted using one of the methods of statistical information processing - correlation analysis. First, it is necessary to calculate the sample average (1):

$$\bar{x} = \frac{\sum_i x_i}{\sum_i n_i} = \frac{11 + \dots + 15}{30} = 14.17 \quad (1)$$

Next, it is needed to find the error of representativeness of the sample average (2):

$$S_x = \sqrt{\frac{\sum_i (x_i - \bar{x})^2}{n(n-1)}} \approx 0.3427 \quad (2)$$

Finally, need to find the coefficient of variation (3):

$$C_x = \frac{S_x}{\bar{x}} \cdot 100\% = \frac{0.3427}{14.17} \cdot 100\% \approx 2.42\% \quad (3)$$

These calculations were performed in MS Excel.

Since in this case, the coefficient of variation is less than 3%, therefore, the participants in the groups do not significantly differ from each other in the number of USE scores in mathematics, and research can be carried out.

As mentioned above, in group No. 1, classes were conducted in a remote format using the course described above, and group No. 2 studied in the audience. At the end of the semester after completing the course, verification work was carried out (in the audience) in both groups (see Table 5). The results of the verification work (in percent) of students selected for research are as follows:

Group No. 1: 62, 70, 80, 78, 74, 65, 75, 76, 60, 76, 60, 74, 64, 58, 78.

Group No. 2: 75, 80, 85, 82, 79, 72, 85, 88, 74, 70, 74, 88, 70, 78, 94.

It is necessary to evaluate how different the effectiveness of the test work is (and, consequently, the result of mastering the discipline as a whole) depending on the form of training. For this, it is necessary to find the coefficient of determination. At the same time, quantitative data (results of verification work) will

be interpreted using one of the methods of statistical information processing - correlation analysis.

First, find the average value and variance in each group.

Group No. 1 (4)-(5):

$$\bar{x}_1 = \frac{\sum_i x_i}{\sum_i n_i} = \frac{62 + \dots + 78}{15} = 70. \quad (4)$$

$$D_1 = \frac{\sum_i (x_i - \bar{x}_1)^2}{\sum_i n_i} = 55,067. \quad (5)$$

Group No. 2 (6)-(7):

$$\bar{x}_2 = \frac{\sum_i x_i}{\sum_i n_i} = \frac{75 + \dots + 94}{15} = 79.6. \quad (6)$$

$$D_2 = \frac{\sum_i (x_i - \bar{x}_2)^2}{\sum_i n_i} = 141,6. \quad (7)$$

It is necessary to find the average value for all students (8):

$$\bar{x} = \frac{\sum_i \bar{x}_i \cdot N_i}{\sum_i N_i} = \frac{70 \cdot 15 + 79,6 \cdot 15}{30} = 74,8. \quad (8)$$

It is needed to compute the intragroup dispersion (9):

$$D_{intragroup} = \frac{\sum_i D_i \cdot N_i}{\sum_i N_i} \approx 98,333. \quad (9)$$

Then, it is necessary to find the intergroup variance (10):

$$D_{intergroup} = \frac{\sum_i (\bar{x}_i - \bar{x})^2 N_i}{\sum_i N_i} = 23,04. \quad (10)$$

Using the two previous values, need to find the total variance (11):

$$D_{total} = 98,333 + 23,04 = 121,373. \quad (11)$$

Finally, it is necessary to calculate the coefficient of determination, which characterizes how strongly the success of mastering the

material and the result of learning the discipline as a whole depends on the choice of the form of training (12):

$$\eta^2 = \frac{D_{intergroup}}{D_{total}} \approx 0,1898. \quad (12)$$

These calculations were carried out in MS Excel.

To improve the quality of distance learning mathematics using the electronic educational course in group No. 1, in addition to the test work, a survey was conducted (see Table 6). Data was collected and then placed in a database to organize information. Quantitative data were interpreted using descriptive analysis.

**Table 6.** Questionnaire Content

| No | Question   |
|----|--|
| 1. | Did you enjoy studying math with the e-learning course?              |
| 2  | Do you think that distance learning is as effective as traditional?  |
| 3. | What are the main advantages and disadvantages of distance learning. |

### 3. RESULTS AND DISCUSSION:

The described experiment was conducted in order to assess the effectiveness of the use of an electronic educational course in the study of the discipline "Mathematics and the foundations of mathematical processing of information." For this, 30 students from two groups (15 people each) were selected. The first group during the semester studied mathematics in remote form using the electronic educational course described above, the second in the traditional form.

The processing of experimental results can be divided into three stages.

Initially, it was necessary to assess how appropriate it was to conduct an experiment among selected students. For this, based on the results of the exam in mathematics, the coefficient of variation was calculated  $C_x \approx 2,42 \%$ .

The coefficient of variation allows to determine whether the subjects differ

significantly from each other according to one or another sign.

It is generally accepted that differences between subjects in some way are insignificant if the coefficient of variation does not exceed 5%. To increase the reliability level of an experiment, this bar is sometimes reduced to 3%. Since in this case, the coefficient of variation is less than 3%, therefore, the participants in the groups do not significantly differ from each other in the number of USE scores in mathematics, and research can be carried out.

In the second stage, it was necessary to evaluate how strongly the success of mastering the discipline "Mathematics and the foundations of mathematical processing of information" depends on the choice of the form of training. To do this, at the end of the semester after studying all sections, verification work was carried out in both groups (see table. 1). Using the correlation analysis based on the results of the verification work, the coefficient of determination was calculated  $\eta^2 \approx 0,1898$ . Translating this value into percent, we have:  $0,1898 \cdot 100\% \approx 19\%$ .

The coefficient of determination allows to determine how strongly the results of the subjects are due to their belonging to a particular group.

The obtained result indicates that the success of mastering mathematics by 19% depends on the choice of the form of training. In order to determine which particular form of training is more effective, we compare the average values of the results of the test work of each group:  $\bar{x}_1 = 70$ ,  $\bar{x}_2 = 79,6$ . Since, therefore, it is traditional learning that is 19% more effective than distance learning.

At the third stage, in order to improve the quality of distance learning mathematics using an electronic educational course, a survey was conducted in group No. 1 (see Table 2).

When answering the first question, 80% (12 people) of the respondents answered in the affirmative.

When answering the second question, approximately 73% of respondents (11 people) answered in the affirmative.

In answering the third question, students identified both the advantages and disadvantages of distance learning. They noted that the advantages of distance learning are that it is possible to study material and perform tasks

anywhere, in any free time, from any electronic device with Internet access. Students also noted a wide variety of teaching and assessment materials. Besides, students indicated that the electronic course is equipped with a lot of background information.

The main disadvantages of distance learning, according to the respondents, are the lack of full communication with teachers and fellow students (80% - 12 respondents), the lack of skills necessary for working with an electronic educational course (60% - 9 respondents), the difficulty of independent study of some topics ( $\approx$  53.3% - 8 respondents), lack of video materials (20% - 3 respondents), negative attitude of parents to distance learning ( $\approx$  13.3% - 2 respondents).

Thus, the results of the survey allowed us to formulate ways to increase the effectiveness of the developed electronic course in the study of mathematics. It is necessary:

- to conduct part of the lessons in the format of a video conference (LMS Moodle does not have a video chat function, however, Moodle can be combined with other software products);
- develop a training manual with a detailed description of the functionality of LMS Moodle or conduct an introductory training session to build skills with the electronic course;
- supplement the most complex topics with video lectures;
- attend orientation lectures with students and their parents to popularize distance learning.

Further research by the authors will focus on improving the quality of distance learning mathematics using an electronic educational course and assessing the effectiveness of distance learning in the study of other academic disciplines involving more students in the experiment.

#### 4. CONCLUSIONS:

The students better assimilated the material in the traditional form of training. However, in cases where a student's presence in the audience is impossible for any reason (illness, family circumstances, etc.), distance courses, make it possible to remotely organize independent work of students and contribute to the development of self-education.

**Table 2.** *Methodical recommendations to the student on the study of the topic*

| <b>Nº</b> | <b>Step</b>  |
|-----------|--|
| 1.        | Learn the lecture material.  |
| 2.        | Answer questions for self-control. If the questions are complicated, you need to study the lecture material again.   |
| 3.        | Study the primary literature, familiarize yourself with additional literature, new publications in periodicals, and familiarize yourself with the glossary.  |
| 4.        | Run a test. Proceeding to the next step requires that there are at least 50% correct answers. If you have less than 50% of the right answers, you need to study the lecture material again and rerun the test. |
| 5.        | Perform test work. Make a report as a file and send it to the teacher for verification.  |
| 6.        | If necessary, you can ask the teacher a question in the forum that arose while studying the topic or offer a topic for discussion.   |

**Table 4. Test tasks**

| Topics<br>(sections)   | Questions   |
|--|---|
| The main means of presenting information in mathematics and their use in pedagogical activity. | <p>1. Experimental studies give:</p> <p>a) criteria for assessing the validity and acceptability in the practice of any theories and theoretical assumptions;</p> <p>b) the approach of the provisions on the study of the assessment of the acceptability of certain conclusions;</p> <p>c) means for obtaining knowledge about the object of study;</p> <p>2. How many stages is the process of mathematical modeling divided into? Write down the answer in numerical format.</p> <p>3. Is the statement true: "The first stage of mathematical modeling is the formulation of laws linking the main objects of the model"?</p> <p>a) yes; b) no.</p> <p>4. What is a translation of text from German into Russian?</p> <p>a) information search;</p> <p>b) data structuring;</p> <p>c) changing the presentation of information;</p> <p>d) obtaining new information.</p> <p>5. The second stage of mathematical modeling is:</p> <p>a) the formulation of laws linking the main objects of the model;</p> <p>b) the study of mathematical problems that lead to a mathematical model;</p> <p>c) ascertaining whether the accepted hypothetical model meets the criteria of practice.</p>   |
| Elements of set theory. Counts. Functions.   | <p>1. Set the correspondence between the name of the set and its designation:</p> <p>1) set of natural numbers;                      a) <math>\mathbb{N}</math>;</p> <p>2) the set of integers;                              b) <math>\mathbb{Q}</math>;</p> <p>3) set of rational numbers.                      c) <math>\mathbb{Z}</math>.</p> <p>2. Were given the following sets: <math>A = \{2; 4; 6\}</math>, <math>B = \{4; 6; 8; 10\}</math>. Find <math>A \setminus B</math>. Choose one answer:</p> <p>a) <math>\{2\}</math>; b) <math>\{4;6\}</math>; c) <math>\{4;6;8;10\}</math>.</p> <p>3. Set the correspondence between the designation of the operation and its name.</p> <p>1) <math>A \Delta B</math>;    a) difference / remainder;</p> <p>2) <math>A \cup B</math>;    b) crossing;</p> <p>3) <math>A \setminus B</math>;    c) combination;</p> <p>4) <math>A \cap B</math>;    d) symmetric difference.</p> <p>4. If <math>A</math> is the set of even natural numbers, and <math>B = \{11, 22, 33, 44, 55, 66, 77\}</math>, then the number of elements of the set <math>A \cap B</math> is equal (write down the answer in numerical format): ...</p> <p>5. If <math>A</math> is a set of natural numbers less than 10, and <math>B = \{8,9,10,11,22\}</math>, then the number of elements of the set <math>A \setminus B</math> is equal (write down the answer in numerical format): ...</p> |

Elements of probability theory.

6. Many points that can be connected by lines are called ....
  7. A closed route is called ....
  8. What is called the Euler path in the graph?
    - a) a path containing all edges of the graph;
    - b) a path that can be drawn on a plane so that no two of its edges have other common points except a common vertex;
    - c) only edges of the directed graph;
    - d) a path containing all edges of the graph whose degrees of adjacent vertices are 1.
  9. The function  $f(x) = x + \sin 2x$  is given. Find  $f(0)$ .
    - a) 0; b) 2; c) 1; d) -1.
  10. Find the domain of the function  $y = \ln(1-x^2)$ .
    - a)  $(0;1]$ ; b)  $(-1;1)$ ; c)  $(-\infty;-1) \cup (1;+\infty)$ ; d)  $[-1;1]$ .
- 
1. In the task "Two shots are fired at a target. Find the probability that the target will be hit once. The test is:
    - a) the target will be hit twice;
    - b) two shots are fired at the target;
    - c) the target will be hit once.
  2. A dice is thrown. Let us designate the events: A - "loss of 6 points", B - "loss of 4 points", D - "loss of 2 points", C - "loss of an even number of points". Then event C is equal to:
    - a)  $C=A+D$ ; b)  $C=A+B+D$ ; c)  $C=A \cdot B \cdot D$ ; d)  $C=A+B$ .
  3. Match:
    - 1) Event - "the letter M is selected from the word MIR "is; a) reliable;
    - 2) Event - "from an urn containing only white balls retrieve white ball "is; b) impossible;
    - 3) Event - "the letter K is selected from the word CHALLENGE is. c) random.
  4. If the complete system consists of 2 incompatible events, then such events are called ...
  5. Two students pass the exam. Events: A - "the first student will pass the exam", B - "the second student will pass the exam" are:
    - a) joint; b) independent; c) incompatible.
  6. Test - "throw two coins." Event - "at least one of the coins will have a coat of arms". The number of elementary outcomes conducive to this event is (write down the answer in numerical format): ...
  7. The probability for a student to pass the first exam is 0.6, the second 0.4. The probability of passing at least one exam is:
    - a) 0,24; b) 0,52; c) 0,76; d) 1.

|                                      |  |
|--------------------------------------|--|
| Elements of mathematical statistics. | <p>8. There are 10 textbooks on the shelf in random order. Of these, 1 in mathematics, 2 in chemistry, 3 in biology and 4 in geography. The student randomly took 1 textbook. What is the likelihood that he will be either in mathematics or in chemistry?</p> <p>a) 0,1; b) 0,2; c) 0,3; d) 0,24.</p> <p>9. There are 2 white, 3 black balls in the urn. Two balls are taken out of the urn in a row. The probability that both balls are white is equal (write down the answer in numerical format): ...</p> <p>10. Projects from three competing firms come for examination. The probability that the project of the first company will pass the examination with a positive assessment is 0.8, the second - 0.6, the third - 0.9. For examination, only one project was chosen at random. He passed it with a good mark. What is the likelihood that this was a project of the first company? Write down the answer in numerical format.</p> <p>1. Which statement about the general and sample populations is true?</p> <p>a) the sample and the population are equal in number;</p> <p>b) the sample - part of the general;</p> <p>c) the population is part of the sample.</p> <p>2. The sum of the frequencies of the sign is equal to:</p> <p>a) 0; b) 1; c) sample size n.</p> <p>3. A polyline, the segments of which connect the points with the coordinates <math>(x_i, n_i)</math>, where <math>x_i</math> is the value of the variational series, <math>n_i</math> - is the frequency, is called ....</p> <p>4. The statistical hypothesis is called:</p> <p>a) an assumption regarding the size of the population;</p> <p>b) an assumption regarding the size of the sample;</p> <p>c) an assumption regarding the parameters or type of distribution law of the population.</p> <p>5. Is the true statement "The sample mean is the interval estimate of the mathematical expectation <math>M(X)</math>, and the sample variance is the point estimate of the variance <math>D(X)</math>"?</p> <p>a) yes; b) no.</p> |
|--------------------------------------|--|

**Table 5.** Verification task for students

| Topics<br>(sections)                                | Task   |
|---|--|
| Elements of<br>set theory.<br>Counts.<br>Functions. | <p>1. Two hundred forty applicants passed the Russian language exam, of which 170 people got a score lower than 5 points, 205 people passed this exam, i.e. got grades 3, 4 or 5. How many people got grades 3 and 4?</p> <p>2. Out of 37 students of the Faculty of Philology, 15 students received an excellent rating in Russian, 14 in literature, 18 in linguistics, 6 in Russian and literature, 9 in Russian and linguistics, in all three disciplines – 4. How many students received at least one mark of "5"?</p> <p>3. Badminton competitions are attended by ten athletes. Competitions are held according to the Olympic system, in which a participant is eliminated from the tournament after the first loss. What is the minimum number of hours that competition can be held if the organizing committee has 2 courts at its disposal and an hour is allocated for each meeting, including warm-up and relaxation?</p>  |
| Elements of<br>probability<br>theory.               | <p>4. For the exam, it was necessary to prepare answers to 30 examination papers. The student prepared only 25 of them. He takes out two examination papers in turn. Find the likelihood that he will pass the exam if it is necessary to answer at least one examination paper for this, and the first examination paper taken by the student contained unlearned questions?</p> <p>5. The same verification work was carried out in two groups. In the first group of 25 students, 8 received the "excellent" mark for their works, in the second, consisting of 30 students, there were 6 "excellent" works. What is the likelihood that the chosen random work from the randomly selected group will be "excellent"?</p>   |
| Elements of<br>mathematical<br>statistics.          | <p>6. Let a set of attribute values be given: 15; 20; 18; 20; 25; 11; 12; 13; 24; 23; 23; 24; 21; 22; 21; 23; 23; 22; 21; 14; 14; 22; 15; 16; 20; 20; 16; 16; 20; 17; 17; 17. It is necessary to compile a variational and statistical series of the distribution, to calculate the numerical characteristics.</p> <p>7. Five students were selected for participation in the programming Olympiad. A computer program records the time for solving each task (three tasks in total):<br/> the time to solve the first task (min): 24, 16, 12, 5, 6;<br/> the time to solve the second task (min): 18, 14, 10, 4, 16;<br/> the time to solve the third task (min): 22, 15, 16, 12, 8.<br/> It is necessary to determine whether there are statistically significant differences between the time of solving the tasks?</p> <p>8. Fifteen first-year students were selected. They were asked the question "How much time did you spend preparing for the standings?" Their answers (in hours): 8, 6, 3, 1, 0, 5, 9, 2, 1, 4, 6, 10, 0, 3, 6. It is necessary to find the coefficient of variation and draw an appropriate conclusion.</p> |

### RESUMO

**Objetivos.** A pesquisa teve como objetivo identificar os híbridos mais produtivos selecionados pelo Instituto *All-Russian* de Pesquisa de Milho para cultivar pela tecnologia de sementes de cereais nas condições naturais dos Cis-Urais. **Metodologia.** O milho foi cultivado para sementes e forragem verde para animais de fazenda nas condições dos Cis-Urais. A massa verde do milho, composta principalmente por caules e folhas, geralmente contém de 88 a 90% de água. A ensilagem preparada para isso possui menos matéria seca e proteínas. Essas forragens têm baixo valor nutricional e baixo retorno dos produtos pecuários. Os alimentos mais nutritivos e de alta qualidade podem ser recebidos a partir de sementes de milho ou de sua massa acima do solo, com grãos leitosos e maduros. Selecionar híbridos de maturação precoce com alto valor nutricional é a principal preocupação do estudo. **Resultados.** Os resultados demonstram que a produtividade dos híbridos de milho varia de 2,50 a 6,76 t/ha, dependendo do solo e das condições climáticas. Quando os híbridos de milho são cultivados por tecnologia de sementes, a massa acima do solo das culturas estudadas é de 30,68-68,80 t/ha. **Conclusões.** É necessário selecionar maturação anterior e híbridos altamente produtivos para aumentar a qualidade e nutrição da ração para milho. Os híbridos recomendados para a produção de grãos são Ural 150 (5,45 t/ha), Baikal (5,38 t/ha) e Mashuk 170 MV (4,98 t/ha); K-170 (56,7 t/ha), Shihan (55,67 t/ha) e Mashuk 170 MV (54,99 t/ha) que proporcionaram uma maior produção da massa verde na maturação grãos leitosos, melhores para produção de silagem. Os dados resultantes permitem selecionar híbridos de milho com alto rendimento e valor nutricional para fazendas com condições similares de solo e clima e desenvolver dietas para gado leiteiro e de corte altamente produtivo.

**Palavras-chave:** massa acima do solo; grão; híbridos; milho; produção.

### ABSTRACT

**Objectives.** The research aimed to identify the most productive hybrids selected by the All-Russian Research Institute of Maize to cultivate by the cereal seed technology in the natural conditions of the Middle Cis-Urals. **Methodology.** Maize was cultivated for seeds and green fodder for farm animals in the conditions of the Middle Cis-Urals. The maize green mass, consisting mainly of stems and leaves, usually contains up to 88-90% water. Silage being prepared for it has less dry matter and protein. Such fodder has low nutritional value and poor return from livestock products. The most high quality and nutritious feed can be received from maize seeds or its above-ground mass with seeds of milky-wax and wax ripeness. To select early-maturing hybrids with high nutritional value is the primary concern for the studied area. **Results.** The results demonstrate that the productivity of maize hybrids ranges from 2.50 to 6.76 t/ha depending on soil and climatic conditions. When maize hybrids are grown by seed technology, the above-ground mass of the studied crops is 30.68-68.80 t/ha. **Conclusions.** It is necessary to select earlier ripening and highly productive hybrids to increase the quality and nutrition of corn feed. The recommended hybrids for grain production are Ural 150 (5.45 t/ha), Baikal (5.38 t/ha) and Mashuk 170 MV

(4,98 t/ha); K-170 (56,7 t/ha), Shihan (55,67 t/ha) and Mashuk 170 MV (54,99 t/ha) that provided a higher output of the green mass at milky-wax ripeness of grain are best for silage production. The resulting data make it possible to select maize hybrids with high yields and nutritional value for farms with similar soil and climate conditions and to develop diets for highly productive dairy and beef cattle.

**Keywords:** above-ground mass; grain; hybrids; maize; yield.

## АННОТАЦИЯ

Цели. Данное исследование имело целью выявить наиболее высокопроизводительные гибриды кукурузы для выращивания в естественных условиях Среднего Предуралья среди отобранных Всероссийским научно-исследовательским институтом кукурузы образцов. Методология. Кукурузу выращивали на семена и зеленый корм для сельскохозяйственных животных в условиях Среднего Предуралья. Зеленая масса кукурузы, состоящая в основном из стеблей и листьев, обычно содержит в своем составе до 88-90% воды. Однако, в готовом силосе сухого вещества и белка содержится меньше. Соответственно, такой корм имеет низкую пищевую ценность и его использование влечет сокращение объемов производства продукции животноводства. Наиболее качественный и питательный корм можно получить из семян кукурузы в фазе молочно-восковой и восковой спелости. Выбор для изготовления корма раннеспелых гибридов с высокой питательной ценностью является основной задачей исследуемой агропромышленной области. Результаты. Результаты данного исследования показывают, что урожайность гибридов кукурузы колеблется от 2,50 до 6,76 т/га в зависимости от почвы и климатических условий. При выращивании гибридов кукурузы в соответствии с семенной технологией, надземная масса исследуемых культур составляет 30,68-68,80 т/га. Выводы. С целью повышения качества и питательности корма, необходимо выбирать более ранние и высокопроизводительные гибриды кукурузы. Рекомендованными для производства зерна являются гибриды Уральский 150 (5,45 т/га), Байкал (5,38 т/га) и Машук 170 MB (4,98 т/га); K-170 (56,7 т/га), Шихан (55,67 т/га) и Машук 170 MB (54,99 т/га), которые обеспечивали более высокую урожайность зеленой массы для производства силоса при созревании зерна молочно-восковой спелости. Полученные данные позволяют выбирать гибриды кукурузы с высокой урожайностью и питательной ценностью для ферм с аналогичными почвенными и климатическими условиями и разрабатывать рационы для эффективного функционирования молочного и мясного скотоводства.

**Ключевые слова:** надземная масса, зерно, гибриды, кукуруза, урожайность.

## 1. INTRODUCTION:

Maize growing is a traditional source of income and subsistence for many farmers and rural populations in rainfed areas. On an industrial scale, in large countries, maize is a cash crop with diverse applications (Novák *et al.*, 2019). It is grown for food, animal feed, as well as a raw material to produce industrial goods (Akinchin and Fedorov, 2015). This crop is cultivated on nearly 150 million hectares in about 160 countries with a wide variety of soils, climate, and management practices, contributing 36% (361.1 million tons) to world grain production (Dahlan *et al.*, 2014; Huato *et al.*, 2016). The United States of America (USA) is the largest maize producer in the world, accounting for about 35% of the total maize production. Corn growing is the driving force of the American economy. The United States has the highest productivity (9.5 tons per hectare) being twice as high as that in other countries. Thus, the average yield in India is 2.5 tons per 1 hectare.

Maize is the third most important food crop after rice and wheat in this country. Almost 80% of

India's cropland is used for maize growing. Maize provides 9% of the national food basket (Adedokun *et al.*, 2018; Barry *et al.*, 2017; Ismagilov *et al.*, 2019; Ngaboyisonga *et al.*, 2012). Russia ranks the twelfth among the world producers of maize with 11.3 million tons. The share of our country in cultivating this crop is just 0.9% of the total world production. North Caucasus and the Central Non-Black Soil Zone are the most productive regions to grow maize in open fields. The plants cultivated there to get enough sunlight and provide an abundant harvest. Some areas grow maize as a fodder crop. These are the Ural, Volga-Viatka, central regions, and Siberia (Sotchenko *et al.*, 2018).

Maize is the main crop with different applications. This cereal crop plays an integral part in agriculture. It enables us to address two challenges: to replenish grain stocks and produce nutritional feed for farm animals. This crop is also used to prepare silage well digested by animals. It is a good milk-making feed. Maize is used as green fodder as well (Akhiyarov *et al.*, 2018; Araya *et al.*, 2019; Lin *et al.*, 2019). The ten largest maize

producers accounted for 79.4% of the total world production in 2018. These are the USA, China, Brazil, Argentina, Ukraine, India, Mexico, Indonesia, South Africa, Romania (Barry *et al.*, 2017; Chung *et al.*, 2019; Venkatesha *et al.*, 2019). The share of the leading 30 producers of maize totals 92.4%. In 2018 this list included Canada, Russia, Nigeria, Hungary, Italy, Serbia, Philippines, Ethiopia, Tanzania, Turkey, Egypt, Vietnam, Germany, Thailand, Pakistan, Spain, Poland, Malawi, Kenya and Zambia (Chung *et al.*, 2019). The USA is a key producer and exporter of maize in the world. In 2018 the share of the country in the global production of this cereal crop accounted for 35.3%. The output was 361.1 mln tons. China is the second-largest maize producer in the world. In 2018 the share of China in the global production of the given cereal crop amounted to 21.1%. The output was 215.6 million tons. Brazil is the third world producer of maize. In 2018 its total output was 79.9 million tons. Argentina ranks the fourth among the largest maize producers in the world, its share in the structure of the global production was 3.2%, and the total output amounted to 33.0 million tons of maize. Ukraine is the fifth in the list of top five world producers of the very cereal crop, with 28.5 million tons.

The largest producers of maize in Russia were the Krasnodar and Stavropol territories, Rostov, and Voronezh regions (see Figure 1).

The area under maize amounted to 569.3 thousand hectares (23.2% of the total area) with an average yield of 64.9 kg/ha. The Stavropol territory (the area under maize is 197.5 thousand hectares with the share in the total cropland being 8.1%) has an average yield of 63.7 C/ha. The Rostov region (189.2 thousand hectares, 7.7%) harvests an average yield of 49.1 C/ha. The Voronezh region (184.6 thousand hectares, 7.5%) has an average yield of 77.2 kg/ha. The Kabardino-Balkar Republic (141.3 thousand hectares, 5.8%) gets, on average, 62.9 C/ha. In 2018, the maize yield for seeds in Russia amounted to 47.9 C/ha, which is 2.2% (1.1 C/ha) less than in 2017. It decreased by 4.4 % (2.2 C/ha) for five years. Over ten years, the yield growth was 24.1% (9.3 C/ha). The yield increased by 166.1% (29.9 C/ha) concerning 2001. The average annual yield of this type of cereal crop in Russia was 25.0 C/ha in 1991-2000. In 2001-2010 it increased to 32.7 C/ha. In 2011-2018 the average annual yield reached 47.6 C/ha (Sotchenko *et al.*, 2018; Ismagilov *et al.*, 2019).

The Food and Agriculture Organization of the United Nations (FAO) predicts that the cultivation of this grain crop will increase from year to year world-wide. Countries with the most favorable temperate climate will have the highest yields of maize (Kedir, 2018; Venkatesha *et al.*, 2019; Xu *et al.*, 2019b).

To produce maize seeds in the northern regions of Russia, it is necessary to develop ultra-early maturing and cold-resistant hybrids that can withstand the soil temperature below the biological minimum for a long time. In the northern zone of maize cultivation, more attention should be paid to the seed quality. Using seeds with low laboratory germination and spread resulted from their long-term storage can prevent the planned stand, delay the seedling emergence. It leads to the weak initial growth of plants and, consequently, to lower yields of seeds (Barry *et al.*, 2017; Pandurovic *et al.*, 2013). To get higher yields with a given population at the optimum sowing time, it is necessary to increase the seeding rate by 10-20% in conditions of the Maize Research Institute and by 20-30% in conditions of the northern parts of the region depending on the hybrid used. It requires taking into account the biological characteristics of maize hybrids to germinate in different conditions, seed reproduction, sowing qualities, and the seeding rate adjusted to specific growing conditions. Maize hybrid Nur turned to be the best hybrid to get guaranteed seeds at earlier sowing time in conditions of the Middle Cis-Urals. The stalk fragility below the ear is primarily determined by the hybrid's genotype and growing conditions. Ear infection with *Fusarium* varies differently from year to year. However, maize hybrid Nur is found to be resistant to this disease independently of other factors (Ismagilov *et al.*, 2019).

Maize hybrid productivity trends in the U.S. prove that the estimated annual improvement rates range from 1.2 to 2.4% (Barry *et al.*, 2017). Studies on the relationship between climate and human activities often place greater emphasis on the science of climate change. The savings were mostly due to temperature and precipitation. The phase transition of economic performance was positively affected by the long-term temperature change in combination with the trigger effect of short-term precipitation changes (Ismagilov *et al.*, 2019). From a more macroeconomic perspective, the climate movement for macroeconomic cycles has been mitigated by larger and slower processes such as social memory, spatial displacement of key economic areas, and socio-technological progress (Chung *et al.*, 2019).

These genetic changes are associated with improved management practices, including fertilizer use, irrigation, tillage, weed, and pest control, as well as crop rotation (Barry *et al.*, 2017; Chavas and Mitchell, 2018; Xu *et al.*, 2019a). The use of fertilizers eliminates the lack of nutrients in the soil, as the maize yield is very sensitive to nitrogen (Lamptey *et al.*, 2018). When possible, irrigation reduces soil water scarcity and drought. Pest and weed populations can be controlled and suppressed by tillage, crop rotation, and the use of pesticides (insecticides and herbicides). For centuries, farmers have used crop rotation to reduce pest and weed infestation and to restore soil fertility (Chavas and Mitchell, 2018).

One of the significant constraints in the middle Cis-Urals is the low nutritional value of feed (Ismagilov *et al.*, 2019). This issue can be addressed by developing new elements in conventional technologies to cultivate crops, paying particular attention to grain-forage crops (Mударисов *et al.*, 2019; Omokanye *et al.*, 2013; Xu *et al.*, 2019b). The main grain crops cultivated in the Russian Federation are maize, barley, oats, wheat, rye. The high concentration of digestible carbohydrates provides high grain energy nutrition for these crops. Maize occupies a special place among other cereal crops as a source of energy (12.2-12.8 MJ of metabolizable energy per 1 kg) (Araya *et al.*, 2019; Emmanuel and Mutimura, 2012).

The climate of the Middle Cis-Urals is sharp continental; the sum of active temperatures is 2000-2200 degrees. To produce high-quality maize fodder in the conditions of this region, it is necessary to cultivate early-maturing hybrids. The crop should have time to mature in a short summer. Maize is a heat-loving plant; it is not tolerant of the temperature decline. As a result of the work performed over many years, plant breeders have created hybrids that meet the requirements of the climate in the Middle Cis-Urals. Thus, the seeds of these hybrids after being sown withstand a decrease in temperature to minus 2° C. While maize seeds germinate within eight days in a warm climatic zone, early-ripening hybrids adapted to the natural conditions of the Middle Cis-Urals germinate at relatively low temperatures for the same time. To achieve milky ripeness, maize needs a period of effective temperatures above 10° C for at least 120 days, including about 70 days with an average daily temperature above 15° C (Sotchenko *et al.*, 2018).

To ensure a sufficiently high yield under variable weather conditions, it is recommended to grow several hybrids in each farm, being different in several properties (Barry *et al.*, 2017; Chung *et al.*, 2019; Emmanuel and Mutimura, 2012). The choice of varieties suitable for cultivation in this area, the correct selection and preparation of seed material are of great importance for the Middle Cis-Urals with its sharp differences in soil and climatic conditions (Akinchin and Fedorov, 2018; Chavas and Mitchell, 2018; Ngaboyisonga *et al.*, 2012). In recent years, several early-ripening hybrids have been created. They develop a seed of milky-wax ripeness even in adverse weather conditions of the Middle Cis-Urals (Sotchenko *et al.*, 2018).

In the conditions of the Middle Cis-Urals, maize is mainly cultivated for silage and green feeding of animals (Sotchenko *et al.*, 2018). However, the green mass of maize, consisting mainly of stems and leaves without ears, usually contains up to 88-90% water. Silage, being prepared from such a mass, has less dry matter and especially protein (Kedir, 2018; Xu *et al.*, 2019b). Such fodder has low nutritional value and relatively low return on livestock products (Lubova *et al.*, 2018). Maize seeds or a groundmass with seeds of milky-wax and wax ripeness can develop the most high-quality and nutritious feed (Hisse *et al.*, 2019).

A maize seed has a high starch content (up to 70%), compared with other cereal crops, it is rich in fat (up to 7%) (Kedir, 2018; Ngeno *et al.*, 2012; Omokanye *et al.*, 2013). Maize seeds contain less calcium (3,5 times less than oats and sorghum, three times less than barley and millet, two times less than rye and 1,5 times less than wheat) (Ngeno *et al.*, 2012; Wakili, 2012). Early-maturing hybrids on their morphological features do not differ in robust development, but they have a significant share of ears in the total harvest due to lack of heat (Barry *et al.*, 2017; Chavas and Mitchell, 2018; Kätterer *et al.*, 2019). When these hybrids are grown according to the cereal seed technology, farms receive high-quality raw material and prepare silage with nutrient content of 0.25-0.32 fodder units. It is found that in the conditions of the Middle Cis-Urals, it is advisable to grow varieties and hybrids with a period of 95-100 day germination-wax ripeness. It provides high yields of dry mass with ears of milky-wax and wax ripeness. Maize fodder with a high content of ears in the phase of milky-wax ripeness of seeds is characterized by a high content of metabolic energy, starch, and fat (Lin *et al.*, 2019; Ngaboyisonga *et al.*, 2012). Maize seed

digestibility is very high and reaches 90%. Digested nutrients are complete. It is not only the seed that is well digested but other parts of the plant as well. Thus, there are 30-40% of seeds, 10% of rods, and stalks without seeds, about 50% of the rest parts of the plant (Akhiyarov *et al.*, 2018; Kätterer *et al.*, 2019; Venkatesha *et al.*, 2019).

## 2. MATERIALS AND METHODS:

### 2.1. The research place

The study of hybrids was carried out on the territory of the Republic of Bashkortostan, occupying a significant part of the Middle Cis-Urals. There are six agricultural zones in the Republic: northern forest-steppe, north-eastern forest-steppe, southern forest-steppe, Cis-Ural steppe, trans-Ural steppe, and mountain-forest zone (Barry *et al.*, 2017; Chavas and Mitchell, 2018; Ismagilov *et al.*, 2019). Field studies of maize hybrids developed by the All-Russian research institute of maize were conducted in the northern forest-steppe ("Agro Tanyp" agricultural production cooperative, located in the Tatyshly district) and southern forest-steppe (scientific training center of the Bashkir State Agrarian University (BSAU)).

In the "Agro Tanyp" farm, the soil cover is represented by dark gray forest soils with medium loamy granulometric composition. The humus horizon depth is 18-22 cm, the humus content in the arable layer is 3.7-4.1 %. The soil medium reaction is slightly acidic pH (kcl) 4.8-5.2; the bulk unit weight of the soil in the arable layer is 1.10-1.14 g/cm<sup>3</sup>. The soil contains 70-80 mg/kg of easily hydrolyzable nitrogen, 111-118 mg/kg of mobile phosphorus, and 121-125 mg/kg of exchange potassium. The frost-free period is 120-125 days. The growing season precipitation is 236-284 mm, with the average annual rainfall being 587 mm. The soil cover in the scientific training center of the Bashkir State Agrarian University is represented by leached chernozem having medium loamy granulometric composition. The humus horizon layer is 58-69 cm; the humus content in the topsoil is 9.7-9.8%. The soil medium reaction is slightly acidic pH (kcl) 4.8-5.2; the bulk unit weight of the soil in the arable layer is 1.02-1.10 g/cm<sup>3</sup>. The soil contains 135-156 mg/kg of easily hydrolyzable nitrogen, 160-166 mg/kg of mobile phosphorus, 185-187 mg/kg of exchange potassium. The frost-free period is 110-135 days. The growing season precipitation is 225-275 mm, with the average annual rainfall being 523 mm.

During the growing season of 2019, meteorological conditions in the Republic of Bashkortostan as a whole, especially in May and June, were cold. The shortage of favorable temperatures amounted to 116 0C for these two months. Though the temperature was a bit higher than usual in the subsequent maize vegetation period, the heat shortage remained.

### 2.2. Equipment

Maize was cultivated according to the following management practice in experiments of the scientific training center of the BSAU: predecessor – spring wheat, tillage – autumn plowing with PN-4-35 to a depth of 26-28 cm, spring harrowing (3BZTS-1.0) and pre-sowing cultivation (CSO-4) to a depth of 5 cm, sowing was carried out on May 10-12 by seeder UPS-8. Row spacing was 70 cm, seeding rate – 80 thousand pieces of seeds per 1 ha to a depth of 5 cm.

### 2.3. Field experiments

In "Agro Tanyp" maize in the experiments was cultivated by the technology generally accepted for this zone. The registered area of plots is 150 m<sup>2</sup>, the number of replication is fourfold. The variants are arranged in a line in the experiment. The field experience was conducted on the following hybrids: Mashuk 140, K-140, K-150, Uralskii 150, Nur, Mashuk 150, Biliar 160, K-160, K-170, Shikhan, Katerina, Baikal, Mashuk 170, Mashuk 175, Mashuk 171, Mashuk 185, Newton, Mashuk 220, Mashuk 250. The variants are arranged in a line in the experiment. The registered area of plots is 150 m<sup>2</sup>, the number of replication is fourfold. The field scheme included hybrids: Mashuk 140, K-140, K-150, Uralskii 150, Nur, Mashuk 150, Biliar 160, K-160, K-170, Shikhan, Katerina, Baikal, Mashuk 170, Mashuk 175, Mashuk 171, Mashuk 185, Newton, Mashuk 220, Mashuk 250.

### 2.4. Data analysis

During the growing season, the height and weight of plants were determined. Yield accounting was performed by the continuous harvest method and weighing the mass of plants and seeds after maize ear threshing. To conduct laboratory analysis, seed samples were chosen. Seed moisture was determined with Wile-55 electronic moisture meter and the drying method in the drying chamber. The seed protein content

was tested with Infracum FT-10 infrared analyzer.

### 3. RESULTS AND DISCUSSION:

According to the results of field studies, it was revealed that maize hybrids mostly formed a pre-harvest height at the level of 160.0-280.0 cm. Better conditions for growth were in the BSAU's scientific training center in the Ufa district (Figure 2). Three hybrids had the maximum height: Mashuk 250 MV (275 cm); Mashuk 220 MV (260 cm), and Shikhan (250 cm). The hybrid K-140 had the minimum height indicators in this experiment (175 cm). In conditions of "Agro Tany" farm, located in the Tatyshly district, the highest height of plants was in hybrids Mashuk 250 SV (260 cm), Mashuk 175MV (250 cm) and Newton (250 cm). The minimum height was found in hybrid K-140 (185 cm).

Seed yield development in maize hybrids in the conditions of two zones were studied along with finding the above-ground mass of the crop in the phase of milky-wax ripeness of seeds. When maize is grown according to the cereal seed technology, the green mass yield of the studied hybrids in the conditions of the BSAU's scientific training center of the Ufa district ranges from 33.7 to 68.8 t/ha (see Figure 3). The top three hybrids in terms of yields included: Mashuk 175 MV (68.8 t/ha), Baikal (59.6 t/ha), and Shikhan (56.7 t/ha). The minimum yield was formed in Mashuk 140 hybrid (33.7 t/ha). There is a close correlation between plant height and yield of green mass ( $r=0.823$ ). In the conditions of the "Agro Tany" farm in the Tatyshly district, the green mass yield of maize hybrids varied within 32.8-56.7 t/ha. The top three hybrids in terms of yields included: K-170 (56.7 t/ha), Shikhan (55.67 t/ha), and Mashuk 170 MV (54.99 t/ha). The K-160 hybrid had the lowest yield (32.8 t/ha).

In the conditions of the Middle Cis-Urals, it is essential to evaluate hybrids by seed moisture at the time of maize harvesting in this zone. Hybrid seeds had different moisture content depending on the group of ripeness (28-63.5%). 2 hybrids, namely Mashuk 140 and K-140, had the lowest moisture content at harvesting. Other hybrids had high moisture content (Table 1). With the standard moisture content being 14%, the seed yield of maize hybrids in the conditions of the "Agro Tany" farm ranged from 3.17 to 6.3 t/ha. The highest yield was received from the hybrid Uralskii 150 (5.45 t/ha). The yields of Baikal (5.38 t/ha) and

Mashuk 170 (4.98 t/ha) hybrids were a bit lower. Under the conditions of the BSAU's scientific training center, the seed yield of hybrids at 14 % moisture content was 2.50-6.76 t/ha. The highest grain yield was provided by the Uralskii 150 hybrid (6.76 t/ha). Relatively high productivity rates were observed for Mashuk 150 (6.57 t/ha), Baikal (6.16 t/ha), and Shikhan (5.89 t/ha) hybrids.

Thus, different soil and climatic conditions made it possible to evaluate and identify highly productive maize hybrids for the conditions of the studied farms. Nur, Uralskii 150, Mashuk 150 MV, Mashuk 170 MV short-season hybrids (FAO 150-199) are the most suitable for the conditions of the northern and southern forest-steppe of the Republic in terms of ripening and yields. To get high-quality as well as high-energy silage, it is advisable to grow short-season hybrids Mashuk 171, Mashuk 175 MV, Mashuk 185 MV, and Katerina SV.

Academician Sotchenko V.S., professor Shlapunov V.N., cytogeneticist McClintock Barbara, plant breeder Borlaug Norman Ernest argue that a higher nutritional value of feed for cows requires hybrids adapted to a particular soil and climate conditions (Barry *et al.*, 2017; Ismagilov *et al.*, 2019; Omokanye *et al.*, 2013). When there is insufficient heat, it is necessary to use early-maturing hybrids. Their yield is not high, but the nutrient content is much higher. These are hybrids of 140-150 FAO (Lin *et al.*, 2019). In conditions with heat security, hybrids of 170-200 FAO can be sown. In Northern Kazakhstan, the average yield of dry matter was 4.8 t/ha (Sotchenko *et al.*, 2018). However, there can be a sharp decline in yields in dry years and when summers are short and cold.

Maize productivity depends not only on climatic conditions but on soil factors and mineral nutrition (Falade *et al.*, 2017; Pandurovic *et al.*, 2013). Under the conditions of Ogallala Aquifer, the maize seed yield ranged from  $5.2 \pm 1.0$  t/ha to  $7.4 \pm 0.7$  t/ha with the highest value when treated with mineral fertilizer and the lowest value when composted with 100% fertilizer (Ayhan *et al.*, 2013; Barry *et al.*, 2017; Lin *et al.*, 2019). The maize productivity largely depended on the level of nutrient supply. Maize programs run by private companies typically conduct extended product testing in multiple growing environments to better recommend new hybrids, as well as providing farmers with an opportunity to evaluate their products by DuPont Pioneer in Minas Gerais and Goias States. The yield of the new hybrids was at

the standard level exceeding the control variants in some conditions (Xu *et al.*, 2019a, 2019b).

To increase the nutritional value of maize silage, there were carried out tests on adding legumes. The latter is considered to be an important element of sustainable agriculture. Legumes provide biological nitrogen fixation that increases the protein content in the diet. Thus, depending on the local conditions, it is necessary to select the elements of technology that increase the productivity of maize hybrids, thereby increasing the nutritional value of feed, taking into account their economic efficiency.

#### 4. CONCLUSIONS:

The plant height of the studied maize hybrids selected by the All-Russian Research Institute in the conditions of the Middle Cis-Urals varies from 160.0 to 280 cm. The seed yield of maize hybrids studied in two soil-climatic zones of the Middle Cis-Urals ranges from 2.50 to 6.76 t/ha. Uralskii 150 (5.45 t/ha), Baikal (5.38 t/ha), and Mashuk 170 MV (4.98 t/ha) hybrids have relatively high seed productivity.

When cultivating maize hybrids on the seed technology, they develop a green mass at the level of 30.68-68.80 t/ha. The hybrids K-170 (56.7 t/ha), Shiha (55.67 t/ha), and Mashuk 170 MV (54.99 t/ha) showed the highest productivity with the milky-wax ripeness phase of seeds. The K-160 hybrid had the lowest yield (32.8 t/ha). The received data will allow selecting maize hybrids with high yield and nutritional value for farms with similar soil and climatic conditions and to prepare diets for highly productive dairy cows and beef cattle.

## RESUMO

A batata compreende uma cultura alimentar estrategicamente importante na Federação Russa. A quimiocalização aprimorada da produção de batata, protegendo-a de pragas e doenças, permite obter altos rendimentos, mas ao mesmo tempo afeta significativamente a qualidade biológica dos produtos. A cadeia varejista frequentemente recebe muitos tubérculos com excesso de nitratos, enquanto contém os chamados pesticidas "de longa duração". Ao entrar no corpo humano com produtos, as substâncias tóxicas causam doenças graves. Há um problema agudo de fornecer às crianças produtos ecologicamente corretos. Essa pesquisa desenvolveu uma importante tarefa de neutralizar o acúmulo de inseticidas e fungicidas tóxicos em tubérculos pelo início da colheita ao cultivar variedades de batatas de médio porte. Isto foi conseguido quando se utiliza o inseticida Celest TOP (Tiametoxame, classe de risco 2) em normas reduzidas em 25%, em combinação com o uso de preparações biológicas Siliplant ou Albit e reduzidas em 40% em normas de fungicidas. O sistema de proteção incluiu: para tubérculos: Celestino 0,3 l/ha + Albite TPS 0,1 l/t; para os tops: Ridomil ouro MC VDG 1,5 kg / ha primeiro, segundo e terceiro tratamentos; Shirlan SK 0,24 l / ha 4-5º tratamento + Albit TPS 2 vezes para vegetação 0,05 l / ha ou Siliplant BP 2 vezes para vegetação 1,0 l / ha. As análises laboratoriais revelaram quantidades residuais de pesticidas e nitratos em tubérculos. Os produtos resultantes, com o sistema de proteção de plantas desenvolvido, atenderam às exigências de nutrição infantil e dietética. O método voltamétrico invertido foi usado para determinar a concentração de pesticidas em tubérculos. Os nitratos foram determinados usando um eletrodo seletivo de íons. Está estabelecido que o Prestige (Imidacloprid, classe de risco 1) é impraticável de usar na produção de batatas ecologicamente limpas. O uso de Celest (Thiamethoxam, classe de risco 2) em combinação com Albit ou Siliplant aumentou o rendimento e reduziu o conteúdo de substâncias tóxicas nos tubérculos.

**Palavras-chave:** *pesticidas modernos, agentes biológicos, nitratos.*

## ABSTRACT

Potatoes comprise a strategically important food crop in the Russian Federation. Enhanced chemicalization of potato production, while protecting it from pests and diseases, allows you to get high yields, but at the same time significantly affects the biological quality of products. The retail chain often receives lots of tubers with excess nitrates, while containing the so-called "long-playing" pesticides. Getting into the human body with products, toxic substances cause severe diseases. There is an acute problem of providing children with environmentally friendly products. This research developed an important task of neutralizing the accumulation of toxic insecticides and fungicides in tubers by the beginning of harvesting when cultivating medium-early varieties of potatoes. This was achieved when using the insecticide Celest TOP (Thiamethoxam, hazard class 2) in reduced by 25% norms, in combination with the use of biological preparations Siliplant or Albit and reduced by 40% norms of fungicides. The protection system included for tubers: Celestine 0.3 l/ha + Albite TPS 0.1 l/t. For tops: Ridomil gold MC VDG 1.5 kg / ha first, second and third treatments. Shirlan SK 0.24 l / ha 4-5-th treatment + Albit TPS 2 times for vegetation 0.05 l / ha or Siliplant BP 2 times for vegetation 1.0 l / ha. Laboratory analyses revealed residual amounts of pesticides and nitrates in tubers. The resulting products, with the plant protection system developed by us, meet the requirements for children's and dietary nutrition. The inversion voltammetric method was used to determine

the concentration of pesticides in tubers. Nitrates were determined using an ion-selective electrode. It is established that Prestige (Imidacloprid, hazard class 1) is impractical to use in producing ecologically clean potatoes. Using Celest (Thiamethoxam, hazard class 2) in combination with Albit or Siliplant increased the yield and reduced the content of toxic substances in tubers.

## АННОТАЦИЯ

Картофель - стратегически важная продовольственная культура в Российской Федерации. Усиленная химизация производства картофеля при защите его от вредителей и болезней, позволяет получать высокие урожаи, но при этом значительно страдает биологическое качество продукции. В торговую сеть нередко поступают партии клубней с превышением нитратов, содержащие при этом, так называемые, «долгоиграющие» пестициды. Попадая в организм человека с продукцией, отравляющие вещества, вызывают тяжелые заболевания. Возникает острая проблема по обеспечению экологически чистой продукцией детей. Нашими исследованиями решена важная задача по нейтрализации накопления токсичных инсектицидов и фунгицидов в клубнях к началу уборки при возделывании среднераннего сорта картофеля. Это достигается при использовании инсектицида Селеста ТОП (по тиаметоксаму 2-й класс опасности) в уменьшенных на 25% нормах, в сочетании с применением биопрепаратов Силиплант или Альбит и сниженными на 40% нормами фунгицидов. Система защиты включала по клубням: Селест Топ 0,3 л/га + Альбит ТПС 0,1 л/т. По ботве: Ридомил Голд МЦ ВДГ 1,5 кг/га первая, вторая и третья обработки. Ширлан СК 0,24 л/га 4-5-я обработка + Альбит ТПС 2 раза за вегетацию 0,05 л/га или Силиплант ВР 2 раза за вегетацию 1,0 л/га. Лабораторными анализами выявлены остаточные количества пестицидов и нитратов в клубнях. Полученная продукция, при разработанной нами системе защиты растений, отвечает требованиям предъявляемым к детскому и диетическому питанию. Для определения концентрации пестицидов в клубнях использовали инверсионный вольтамперометрический метод. Определение нитратов проводили с помощью ионоселективного электрода. Установлено, что Престиж (по имidakлоприду 1-ый класс опасности) нецелесообразно применять в производстве экологически чистой продукции. Применение инсектофунгицида Селест (по тиаметоксаму 2-й класс опасности) в сочетании с биопрепаратами Альбит или Силиплант повышало урожайность и уменьшало содержания токсических веществ в клубнях.

**Ключевые слова:** *современные пестициды, биопрепараты, нитраты.*

## 1. INTRODUCTION:

Potatoes comprise a strategically important food crop in the Russian Federation. The population even calls it a "second bread". Pests and diseases may severely damage potatoes. The fight against some of them has become a routine in potato cultivation. These dangers primarily include the Colorado potato beetle, wireworm (elaterid larva), dangerous fungal diseases (late blight), bacterial rot, and various viral diseases. The annual under-harvest of potatoes because of these factors depends on the variety and ranges from 20 to 30%. In adverse years, the under-harvest can be exceeded by 50% (Tulcheev and Yagforov, 2014). An integrated system for the protection of potatoes from diseases, pests, and weeds is a set of measures, among which the chemical method is the primary one (Zeyruk *et al.*, 2019b). The enhanced chemicalization of potato production allows for getting high yields, but the biological quality of the product can suffer greatly (Butov, Zakharov, and Zubkova,

2019). Often the over-nitrated tubers containing so-called "long-lasting" pesticides arrive at shops and markets (Damodaran, Tarkin, and Fennema, 2012). These pesticides may cause serious illnesses in human beings when consumed (Kaplin, 2007). They also have an allergenic and carcinogenic effect and may destroy human immunity (Chernikov and Sokolov, 2014). Chemophobia is becoming more popular among the population. People are wary of products grown industrially and they do not tend to learn more about the technological processes, it is enough for them to know about the use of pesticides and fertilizers in agriculture (Edelev, Grebenkin, Baranov, and Royev, 2013). This may undermine not only the physical but also the spiritual health of a person (Lysenko and Dogadina, 2015). Another urgent problem is the poor preservation of tubers in the post-growing season (Simakov, Starovoitov, and Anisimov, 2013). A complete rejection of pesticides at the current level of agronomic science development is impossible. However, it is quite possible to reduce significantly their

negative impact (Fokina, Ogorodnikova, Olkova, Skugoreva, and Lyalina, 2015). Potato cultivation in the Central black-earth region of the Russian Federation is becoming increasingly complex from year to year and requires serious measures and financial influx to control pests and diseases (Fedotov, Butov, and Goncharov, 2005). The most dangerous is the Colorado potato beetle (*Leptinotarsa decemlineata*) and late blight disease. Without proper measures on protecting, these pests and diseases can cause huge damage to the yield of the crop. They may reduce the yield by 60-70%, and destroy it (Zeyruk *et al.*, 2019a). Recently, there appeared modern, highly effective pesticides with a hazard class lower than the previous generation. There is a need to develop a new system for protecting potato plants from diseases and pests with a reduced rate of pesticides in combination with biological agents (Zeyruk *et al.*, 2019a; Rabinovich and Fomicheva, 2018). Around thirty years ago, there was outstripping growth in population demand for ecologically clean products in Western Europe and North America (Kochurko, Abarova, and Zuev, 2013). Russian Federation does not have legislation, certification, and policy of financial support for ecologically clean products. Producers of biologically high-quality potatoes need clear recommendations for guaranteed production of a sufficiently good, ecologically clean tuber crop (Butov and Boeva, 2013).

The purpose of the study was to establish methods of effective protection of potato plants from pests and diseases. It is needed to reduce pesticides and get ecologically clean products. Besides, it was aimed to substantiate the methods of using Celest (with a hazard class lower than the previously used agent Prestige) in combination with Albit and Siliplant.

The scope of the research included the development of an effective and environmentally friendly system for the comprehensive protection of potatoes from economically significant pests and pathogens in the black-earth forest-steppe of the Russian Federation using modern plant protection products and methods.

The scientific novelty of the research is the development of combining Celest (a modern insectofungicide) with Albit, Siliplant at reduced pesticide rates to obtain ecologically clean, a good level of the potato harvest.

## 2. MATERIALS AND METHODS:

Field experiments were carried out in 2015-2017 at the educational experimental farm of Bunin Yelets State University (Lipetsk region, Russian Federation). The soil of the plots was leached black-earth, medium loamy with a 5.8% humus content (according to Tyurin). The area of the experimental plot was 54 m<sup>2</sup>, and the repetition of the experimental cases was 4-fold/ Potato variety is mid-season Nevsky. The planting density of tubers is 54–55 thousand/ha at potato spacing - 75 cm. Mineral fertilizers in a dose of N<sub>75</sub>P<sub>150</sub>K<sub>120</sub> were applied in the general background in spring, after separating the experiments following the research program. Nitrogen dose (N<sub>75</sub>) in full mineral fertilizer was reviewed in the previous studies on nitrates in experiments with fertilizers (Butov *et al.*, 2019). In the spring, the soil underwent the pre-planting treatment upon the onset of its physical ripeness. Potato planting during the years of the experiments depended on weather conditions and occurred from May 11 to May 14. Harvesting and accounting of the crop were in the third decade of August.

The inversion voltammetric method (GOST R 51301–99) was used to determine the concentration of pesticides in tubers. Nitrates were determined according to the procedure based on the extraction of nitrates from the analyzed material with a solution of aluminum-potassium alum, followed by measuring their concentration in the resulting extract using an ion-selective electrode (Mineev, 2011). The analysis-of-variance method by Dospekhov (2012) was applied to process the crops mathematically.

In the experiments, the following agents were applied: Ridomil Gold MZ (Mancozeb), which is a systemic fungicide against potato diseases, Revus (Mandipropamide + Difenconazole), which is a translaminar fungicide, Shirlan (Fluazinam), which is a contact fungicide, and Prestige SC (Imidacloprid + Pentacuron), which is an insectofungicidal agent. The Imidacloprid pesticide has the highest, first hazard class. Celest TOP, SC (Thiamethoxam + Fludioxonil + Difenconazole) has the second hazard class, which is less than that of Prestige. Prestige SC and Celest TOP are combined insecticidal fungicide protectants for seed potato tubers. Albit is an effective complex biological agent, a universal plant growth regulator, with the properties of a fungicide and

complex fertilizer. Siliplant is a complex fertilizer; its active substance is bioactive silicon in chelated form, supplemented with trace elements (iron, zinc, magnesium, copper, boron).

Spraying seed tubers with dressing agents was done directly in the combined seed planter "Grimme" during planting. Following the research scheme, knapsack sprayers were used to treat the studied agents in vegetating plants. Tuber samples were analyzed for residual fungicides in case 3, where full pesticide rates were applied.

### 3. RESULTS AND DISCUSSION:

Economically significant pests and pathogens of diseases can significantly reduce the potential yield of potatoes (Zeyruk *et al.*, 2019a). Account of the tuber yield in the harvesting experiment showed that the modern means and methods of plant protection had a noticeable effect on its value (Table 1). Thus, the first control case with plant protection only against the Colorado potato beetle (*Leptinotarsa decemlineata*) (fungicides were not used) delivered a yield of 23.5 t/ha. The yield increased to 34.1 and 34.9 t/ha respectively with an intensive system of plant protection against pests and diseases in combination at full rates of pesticides and new biological agents for cases 4 and 6. All other cases, except for the control case, envisage measures to control the Colorado potato beetle (*Leptinotarsa decemlineata*) by applying insectofungicides to tubers (in the planter's opener) when planting.

The modern insectofungicide Celest Top was more effective than Prestige. The yield increase in case 3 (Celest) was 1.7 t/ha compared with case 2 (Prestige). Adding Albit at full pesticide rates to the plant protection system in case 4 increased the yield by 3.4 t/ha, compared to the similar case 3, which did not have biological agents. Case 6 with Siliplant demonstrated a slightly higher yield (0.8 t/ha) than with Albit (case 4). However, this difference did not exceed the experimental error (1.6 t/ha) i.e. it is not reliable. The cases 5 and 7 with reduced by 40% rates of fungicides and Celest Top demonstrated yield decrease by 25%. The case 5 with Albit demonstrated yield decrease (in comparison with the case 4) by 2.6 t/ha. The case 7 with the Siliplant demonstrated

yield decrease by 1.8 t/ha (in comparison with the case 6).

However, despite a significant decrease, the yield level at reduced pesticide rates, but in combination with Albit or Siliplant biological agents, remained at a fairly high level - 31.5-33.1 t/ha against 23.5 t/ha for the control case. A slight decrease in yield can be neglected, when the production will be tasked with obtaining ecologically clean from pesticides potato products for baby and diet nutrition. The results of laboratory studies showed that the residual amount of insecticide in the tubers of the first (control) case was not detected when processing only on tops 40 days after the last spraying (Table 1).

Analyzes of the residual pesticide content in the tubers, according to the test cases, were done 4 times during the growing season with an interval of 10 days. The previously widely used Prestige (case 2), due to the Imidacloprid content, belongs to the first, highest class of danger. Besides, when determining Imidacloprid residual amounts in tubers, it turned out that its content was significantly higher in all cases of determination than the Thiamethoxam (Celest) content, which was used in case 3.

Thus, when determining 65-75 days after the treatment of tubers in the samples from the case 2, the content of Imidacloprid was 16.1% and 15.8% more than in the same periods for Thiamethoxam in the case 2 (Celest). In 95 days after the treatment of the tubers, at the end of the growing season and before harvesting, the content of Imidacloprid (case 2) in the samples was small, but it was 3 times higher than the content of Thiamethoxam in the case 3. This means that Prestige, in comparison with Celest, not only initially belongs to the first, highest hazard class, but it also significantly exceeds the toxicants content in tubers compared to cases with Celest throughout the growing season. This indicates that the Prestige (Imidacloprid) is a "long-lasting" pesticide. It is impractical to use it in the cultivation of potatoes to get ecologically clean products. Adding Celest, Albit, and Siliplant to the plant protection system effected positively not only by increased yields but also by a reduced content of toxic substances in tubers. Albit and Siliplant in combination with Celest effectively neutralized the level of toxic substances accumulation in tubers. This is especially noticeable when Celest's doses are reduced by 25% and when fungicides of various

classes are reduced by 40%. When treating seed tubers with Albit RP and then using it during the following two treatments at the vegetating plants as in the case 4, the level of the residual amount of Thiamethoxam decreased compared to the case 3, without Albit. Thus, Thiamethoxam content decreased by 2.7% on the 65th day after the treatment of tubers; and its content decreased by 15.4% on the 75th day after the treatment of the tops. Before harvesting on the 95th day after the completion of treatments with biological agents, the insecticide concentration in case 4 decreased by 47.8% compared to case 3, without Albit. A decrease in pesticide rates (by 25% of insecticide and by 40% of fungicides) in case 5 with Albit contributed to a more significant decrease in Thiamethoxam content in potato tubers. In the first stages of determination, 65 and 75 days after the treatment of tubers in the case 5, Thiamethoxam content was 25.4-25.9% less than with the full rate of insecticides in the same period in the case 4. A similar trend continued further in terms of determination. Thiamethoxam was not found in the tubers on the 95th day in case 5 with reduced Thiamethoxam rates. At reduced pesticide rates and with Albit RP, a complete absence of the Thiamethoxam insecticide in the potatoes is achieved at the time of harvesting. This fully complies with strict requirements (*SanPin 2.3.2.1078-01*, 2002) for ecologically clean potato products intended for children and medical institutions.

The plant protection system in cases 6 and 7 with Siliplant was the most successful, not only in terms of yield but also in terms of the lowest content of harmful substances in tubers at all times of determination. In case 7 with Siliplant and at reduced pesticide rates as well as in case 5, the insecticide in the tubers was reliably absent before harvesting (95 days after). As for case 6 with Celest and at full rates of pesticides, only traces of the Thiamethoxam insecticide were found in 2015 on the 95th day before harvesting. In 2016 and 2017, there was no insecticide in tubers in case 6 before harvesting. It should be noted that starting from a period of 75 days after the treatment of tubers with pesticides, the residual amount of insecticides (from 0.038-0.032 to 0.028-0.017 mg/kg) in almost all (2-7) cases did not exceed Maximum permissible level (MAL) of 0.05 mg/kg in raw tubers. However, before harvesting, their concentrations in cases 2, 3, and 4 were significantly lower than MAL - from

0.007 to 0.0012 mg/kg. The yield of crops obtained on the indicated cases corresponds to sanitary and hygienic requirements and standards (*SanPin 2.3.2.1078-01*, 2002), as ecologically clean potatoes suitable for the nutrition of the adult population. Toxic substances were not found by the time of harvesting in cases 5, 6, and 7. Therefore, the system of plant protection from pests and diseases studied in these cases can be recommended for the production of ecologically clean potatoes.

Figure 1 shows the dynamics of Thiamethoxam decomposition in tops and tubers when using Celest TOP. Figure 1 shows that Thiamethoxam persists in the tops of potatoes after processing the tubers when planted with Celest TOP at the level of 0.069-0.031 mg/kg for 85-95 days. This provides a long-term protective effect of Thiamethoxam against an economically significant pest - the Colorado potato beetle (*Leptinotarsa decemlineata*). Such protection of vegetating plants from the pest is quite enough for the medium early variety Nevsky.

At the same time, two fungicides that are part of Celest TOP protect young seeds from black speck and other crop diseases starting from the date of planting tubers. The dynamics of Thiamethoxam decomposition, as follows from Figure 1, was parallel to the toxicant's decomposition in the tops, although not strictly proportionally. Thus, for example, on day 95, the tops of case 6 demonstrated the presence of 0.031 mg/kg. However, it was already absent from the tubers.

In the first period of determination, 65 days after planting in the case 6 with full pesticide rates, the content of insecticide in tubers was 28.6% higher than the MAL values (0.05 mg/kg). At the same time, in the case 7 with the reduced by 25% Celest rate, the residual amount of Thiamethoxam (exceeding MAL only by 2%) was actually at the maximum allowable level (MAL). A positive difference towards a lower content of residual insecticide with reduced Celest rates (case 7) persisted throughout the growing season. When analyzing samples 95 days after treatment, Thiamethoxam was not found in the tubers in the cases presented in Figure 1, which indicates complete decomposition of the toxicant. Thus, the present studies have solved the important task of neutralizing the accumulation of toxic insecticides in tubers by harvesting time when cultivating a medium

early variety of potato. This is achieved by using Celest TOP in rates reduced by 25%, in combination with Siliplant or Albit and fungicide in rates reduced by 40%. Production of ecologically clean potatoes is guaranteed with the most acceptable plant protection system in cases 5 and 7.

During the growing season, three types of fungicides were used in the recommended (*Directory of pesticides ...*, 1917, 2015, 2016) and reduced by 40% rates following the experimental design to protect plants from diseases on tops. These included Ridomil Gold MZ WDG (systemic product), Revus SC (translaminar product), and Shirlan SC (contact product). Ridomil Gold MZ WDG is a toxic fungicide because of Mancozeb content: the second hazard class for humans and the third hazard class for bees. The residual amount of Mancozeb (Ridomil Gold MZ WDG) in the samples of tubers taken 5 days after the treatment of potato plants amounted to 0.024 mg. After 10 days, it amounted to 0.002 mg, and after 20 days, this fungicide was not found. In this case, the acceptable value for Mancozeb is 0.1 mg/kg. Revus fungicide containing two active Mandipropamide 25% and Difenconazole 25% is not dangerous for the environment, humans, and bees because of low toxicity. The hazard class for mammals is three and for bees is also three. There are no restrictions on using it in the sanitary zone around fisheries. It quickly decomposes in plants (7-10 days) (*Directory of pesticides ...*, 1917, 2015, 2016). No residual amount of this fungicide was tested due to its low toxicity and rapid decomposition. Shirlan with the active substance of Fluazinam (500 g/l) is hazard class 2 for humans and hazard class 3 for bees. However, the agent is harmful to the inhabitants of water bodies. MAL for potatoes is 0.05 mg/kg. In the present studies, the tuber samples were taken 5 days after treatment contained 0.031 mg/kg of Fluazinam, 10 days after - 0.003 mg/kg, 20 days after - no fungicide was found. The results of analyzes on the residual amount of fungicides indicate a relatively rapid decomposition in tubers. Already 10 days after the last treatment, the amount of fungicides is only 0.002-0.003 mg/kg, and after 20 days, they are completely absent. Besides, the fungicides, which were studied, belong to medium or low toxic hazard classes (2 and 3). As a result, the fungicides used in the experiments did not create an obvious strain in fulfilling the task of obtaining ecologically clean potatoes. However, for guaranteed quality of

products supplied to children and medical institutions, it is advisable to reduce the rates of fungicides by 40%, as it is done in cases 5 and 7. In general, the level of chemicalization of cultivation should be significantly reduced when performing such a task to avoid inconsistencies and errors arising in large-scale production.

Nitrates are a significant hazard to human and animal health. Nitrites are formed from nitrates in the gastrointestinal tract of humans and warm-blooded animals. Nitrites cause severe illness in people due to the formation of methemoglobin in the blood. This is especially dangerous for children. The approved MAL of nitrates in potatoes for children and medical institutions set by the Russian Federation standards is not more than 80 mg/kg per raw tubers. MAL for adults is set at 250 mg/kg (*SanPin 2.3.2.1078-01*, 2002). The World Health Organization (WHO) has established the maximum non-dangerous daily dose of nitrates for humans with their systematic intake in the range of 3.65 mg per 1 kg of body weight (Edelev *et al.*, 2013). Developed countries of the European Union set the maximum allowable level of nitrates in potatoes for baby food within 3 mg% (30 mg/kg) (Damodaran *et al.*, 2012). Some researchers predict in advance nitrate accumulation in tubers by analyzing their content in potato leaves during the growing season (Dreyer, Bohm, and Dresow, 2011). Tubers were sampled in the experiment for analyzing nitrate content along the diagonal of the plot. This related to the general background of mineral fertilizers in the experiments, which was the dose of  $N_{75}P_{150}K_{120}$ . In 2015, the average experimentally observed nitrate content was 71.7 mg, in 2016 - 65.4 mg, in 2017 - 78.5 mg/kg of raw tubers. On average, over three years, with a predominance of 2 times in the proportion of phosphorus and of 1.6 times in potassium over nitrogen in the mineral fertilizer ( $N_{75}P_{150}K_{120}$ ), the nitrate content in tubers was 71.9 mg/kg at MAL equaling to 80 mg/kg for children and medical institutions. The predominance of the proportion of phosphorus and potassium over nitrogen in the fertilizer in a ratio of N:P:K equal to 1:2:1.6 inhibits the accumulation of nitrates in potato tubers. This fact underlines the importance of introducing increased doses of phosphorus to obtain potatoes with low nitrate content. If being guided by the standards of the European Union in terms of the nitrates content in potato products intended for children and diet food, when the content should not exceed 3 mg% (30

mg/kg), it is recommended to follow the previous studies (2011-2013). These studies found that only the dose of  $N_{30}P_{90}K_{60}$  with a nitrate content of 20.8 mg/kg meets the EU requirements. Since the subsequent dose of  $N_{60}P_{90}K_{60}$  results in 47.7 mg/kg of nitrates (Butov *et al.*, 2019).

#### 4. CONCLUSIONS:

1. There is a system in the Central Black Earth region of the Russian Federation, which has been developed to protect plants from pests and diseases for the medium-early variety of potatoes and which ensures a good level of yield and ecologically clean products. This goal can be achieved by using modern plant protection agents, a hazard class lower than the previous ones, in combination with new Albit and Siliplant, and reduced pesticide rates.

2. The protection system should include the treatment of tubers when planted with Celest TOP insectofungicide at a rate of 0.3 l/t reduced by 25% in combination with Albit RP 0.1 l/t or Silipant WS 0.04 l/t. For vegetative plants, fungicide rates are reduced by 40%, in combination with biological agents, including Ridomil Gold MZ WDG 1.5 kg/ha - the 1st treatment; Revus SC 0.36 l/ha - 2nd and 3rd treatments; Shirlan SC 0.24 l/ha - 4th and 5th treatments; Siliplant 2 times during the growing season 1.0 l/ha or Albit 2 times during the growing season 1.0 l/t. Such a plant protection system is guaranteed to ensure the production of medium early potato products, which are ecologically clean from pesticides and which are intended for children and medical institutions.

3. A good yield of 31.5-33.1 t/ha, with a nitrate content of 71.9 mg/kg, not exceeding the MAL for children and dietary nutrition of 80 mg/kg, was obtained against the background of the application rate of mineral fertilizers in a dose of  $N_{75}P_{150}K_{120}$  kg/ha with a ratio of N:P:K equal to 1:2:1.6. Reducing the nitrate content in tubers to EU standards of 3 mg % (30 mg/kg) can be successfully achieved by reducing the dose of nitrogen ( $N_{75}$ ) in full mineral fertilizer by at least two times.

**RESUMO**

Os recursos de implementação do ciclo de vida para a maioria das plantas são específicos da espécie, o que se reflete em uma mudança nas esferas morfológicas, anatômicas e fisiológicas da planta. Um estudo da ontogenese das plantas permite uma compreensão mais profunda das características coenóticas da população e do grau de influência do meio ambiente na implementação da ontomorfogênese das plantas. Este trabalho é dedicado ao estudo do ciclo de vida de uma das espécies taxonomicamente controversas de Crimeia - *Scutellaria stevenii* Juz. O estudo da ontogênese de *Scutellaria stevenii* foi realizado na natureza e para mudas e indivíduos jovens em laboratório. Os princípios de identificação e contabilização de critérios qualitativo-quantitativos foram utilizados para identificar características morfológicas características de vários estados etários. O estudo da estrutura anatômica dos órgãos vegetativos (raiz, caule, brotação) foi realizado com preparações temporárias de um tecido vivo, com métodos padrão. Nesse estudo, o ciclo de vida de *Scutellaria stevenii* contém 4 períodos ontogenéticos e 10 estados etários, que são realizados na ontogenese total ou parcial. No caso de desenvolvimento normal, a ontogênese dos genetes dura de 10 a 16 anos. Em indivíduos virgens que crescem em ecótopos móveis, foi encontrado um tipo de desenvolvimento polivariável. Indivíduos polvariantes formam o arbusto primário com xilorzomas de diferentes comprimentos que exercem a função de fixação adicional no solo e a formação de arbustos parciais que perdem sua conexão com o indivíduo primário pela idade geradora. A capacidade de indivíduos pré-regenerativos de se estabelecer vegetativamente pode ser considerada como adaptação compensatória devido à alta morte de mudas em fitocenoses naturais. As características anatômicas do caule e da raiz de várias idades indicam a partição incompleta morfológicamente não expressa. Esses critérios são uma adição importante à identificação morfológica da idade.

**Palavras-chave:** ciclo de vida, tipo de desenvolvimento polivariável, Crimeia.

**ABSTRACT**

The life cycle implementation features for most plants are species-specific, which is reflected in a change in the morphological, anatomical and physiological spheres of the plant. A study of plant ontogenesis allows a deeper understanding of both the coenotic features of the population and the degree of influence of the environment on the implementation of plant ontomorphogenesis. This work is devoted to the study of the life cycle of one of the taxonomically controversial species for Crimea - *Scutellaria stevenii* Juz. Ontogenesis study of

*Scutellaria stevenii* was carried out in nature and for seedlings and juvenile individuals in a laboratory. The concept of a discrete description of ontogenesis was used to describe the life cycle of *Scutellaria stevenii*, under which to revealed a group of anatomical and morphological features characteristic of each ontogenetic state. The study of the anatomical structure of the vegetative organs (root, stem, flower-bearing shoot) was carried out using temporary preparations of a living tissue with standard methods. In this study the life cycle of *Scutellaria stevenii* contains 4 ontogenetic periods and 10 age states, which are realized in full or partial ontogenesis. In the case of normal development, ontogenesis of genets lasts 10-16 years. In virginal individuals growing on mobile ecotopes, a polyvariant type of development have been found. Polyvariant individuals form the primary bush with xylorizomes of different lengths which carry the function of additional fixation in the soil and the formation of partial bushes that lose their connection with the primary individual by the generative age. The ability of pregenerative individuals to vegetatively established in our study can be considered as compensatory adaptation due to the high death of seedlings in natural phytocoenoses. The anatomical features of the stem and root of various age states to identify morphologically unexpressed incomplete partition. These criteria is an important addition to the morphological identification of age.

**Keywords:** *life cycle, polyvariant type of development, Crimea.*

## АННОТАЦИЯ

Особенности реализации жизненного цикла для большинства растений видоспецифичны, что отражается в изменении морфологической, анатомической и физиологической сферах растения. Изучение онтогенеза растений проводится с целью более глубокого понимания, как ценотических черт популяции, так и для выяснения степени влияния среды обитания на реализацию онтоморфогенеза растения. Данное исследование посвящено изучению жизненного цикла одного из таксономически спорных для Крыма видов – *Scutellaria stevenii* Juz. Изучение онтогенеза *Scutellaria stevenii* проводилось в природе и частично (проростков и ювенильных особей) в лаборатории. Для описания жизненного цикла шлемника Стевена использована концепция дискретного описания онтогенеза, согласно которой выявляется группа анатомо-морфологических признаков, характерных для каждого онтогенетического состояния. Исследование анатомической структуры проводилось с помощью временных препаратов, изготовленных вручную с использованием живых растений стандартными методами. В жизненном цикле *Scutellaria stevenii* выделено 4 онтогенетических периода и 10 возрастных состояний, которые реализуются в форме полного или частичного онтогенеза; в случае нормального развития онтогенез генеты длится 10-16 лет. У виргинильных особей, произрастающих на подвижных экотопах, обнаружен поливариантный тип развития, при котором первичный куст образует различной длины ксилоризомы, несущие функцию дополнительного закрепления в почве и образования парциальных кустов, которые к генеративному возрасту теряют связь с материнской особью. Установленная в нашем исследовании способность особей прегенеративного периода к вегетативному размножению, может рассматриваться как компенсаторная адаптация, обусловленная высокой гибелью проростков в естественных фитоценозах. В анатомическом строении корня и побега наблюдается неполная, морфологически невыраженная партикуляция, ограниченная, главным образом, зоной корневой шейки и базальной части главного корня. Эти критерии являются важным дополнением к морфологической идентификации возраста.

**Ключевые слова:** *жизненный цикл, поливариантность развития, Крым.*

## 1. INTRODUCTION:

*Scutellaria* L. - the numerous polymorphic genus of the family Lamiaceae (Labiatae) has more than 460 species according to the APG II system (The Plant List, 2019). *Scutellaria* genus presented to 5 species *S. albida* L. subsp. *albida*, *S. albida* subsp. *colchica* (Rech. f.) J.R. Edm., *S. altissima* L., *S. galericulata* L. and *S. orientalis* L. subsp. *orientalis* in the Crimea (2,3). Species composition of the genus *Scutellaria* has always had controversial issues, some of which continue to the present, especially regarding the intraspecific structure of *S. orientalis* L. (Pichugin, 2011; Yena, 2012).

Five Crimea endemic species *S. heterochroa* Juz., *S. hypopolia* Juz., *S. hirtella* Juz., *S. taurica* Juz. and *S. stevenii* Juz. were described by S. Yuzepchuk independent of *S. orientalis* based on morphological differences in the structure of the leaf blade and the pubescent character (Komarov, 1954). Such an opinion was supported and reflected in the summary of the flora of the Crimea peninsula by E. V. Wulf (1966) and V. Golubev (1996). The opposite view was expressed by D. Dobrochaeva, M. Kotov (Mosyakin, Fedoronchuk, 1999), according to which, described by S. Yuzepchuk, species

should be considered a different geographical race of *S. orientalis* (Yena, 2012). A similar trend is also incorporated in the last review of the flora of Crimea, in which the species is listed as *S. orientalis* L. subsp. *orientalis*. However, recent studies have shown a more complicated composition of *S. orientalis* distributed in the peninsula and the possibility of isolating distinct species. Such disagreements indicate the need for detailed research of the genus *Scutellaria* in the Crimea and the search for more "strong" keys for the differentiation of species (Pichugin, 2012).

Biomorphological features act as additional taxonomic criteria for distinguishing species (Savinykh et al.; Notov and Kusnetzova, 2004). At present, the life cycles of *Scutellaria* species growing on the territory of the Russian Federation have been described for *S. baicalensis* Georgi (Banaeva, 2000), *S. tuvensis* Juz., *S. galericulata* L., *S. supina* L., *S. tuvensis* Juz. (Guseva, 2013a,b,c,d).

The goal of this study was to identify the anatomical and morphological features of the age states of the life cycle of a well-differentiated species *S. stevenii*. The data on this ornamental plant is scarce and mainly concerns its distribution on the peninsula (Pichugin, 2012). The keys proposed by V. Pichugin for identifying 6 disputed subtaxa, among which *S. stevenii* is also included, are not sufficiently convincing and need further clarification.

## 2. MATERIALS AND METHODS:

The classification of life forms of higher plants by I. G. Serebryakova (1954; 1964) and Savinykh (2015) was adopted as the basis for the identification of types of biomorphs. The definition of the type of ontogenesis and variants of polyvariant development was carried out according to the classifications proposed by L. A. Zhukova (1983; 1995; 2001; 2013). At the heart of the allocation of age groups was the idea of T.A. Rabotnov (1950) about the division of the life cycle into four periods: latent (dormant seed time); virginal (from seed germination to reproduction of an individual in a generative way); generative; senile (senile). Rabotnov's ideas were supplemented by Uranov (1975) and his followers (Coenopopulations of plants ..., 1976, 1988; Nukhimovsky 1997; Ontogenetic Atlas ..., 1997, 2000, 2002, 2004; Zlobin (2012) as a result the modern periodization of the life cycle includes 4 periods, 2 subperiods

(embryonic and latent) and 12 ontogenetic ages: seeds (se), juvenile (j), immature (im), virgin (v), early ( $g_1$ ), mature ( $g_2$ ), later ( $g_3$ ) generative states, subsenile (ss) and senile (s) states).

The life cycle of *S. stevenii* was monitored at the 3 years in two natural populations growing in the foothill Crimea. The sample of plants for each age group was 30 individuals. Morphological parameters were measured in the natural population (Cheremisina et al., 2017, 2018). Seedlings and partially juvenile plants were observed in conditions of artificial cultivation.

Before germination, the seeds were sterilized in 3% hydrogen peroxide solution for 10 min and 70% ethanol for 1 min and then washed in 3 times 45 minutes in sterile distilled water. Then the seeds were transferred to a moistened filter paper, 50 pieces each, in sterile Petri dishes, and placed in a thermostat at 20-30. Seed germination was conducted in 2-fold repetition. Seed germination was determined on the seventh day (GOST, 2011; Zaripova, 2016).

Conclusions about the age of plants were taken based on the degree of xylem development and the number of annual rings of the primary root and stem. Anatomical cuts were carried out on live drugs (preparations) with 3-5 multiples for each age condition. Floroglucin dye was used to stain xylem tissues (Lotova, 2001; Barikina, 2004; Serebryakova, 2006). The microscopy of permanent and temporary preparations was carried out using the Olympus CX31RTSF microscope. The objects were photofixed by the Olympus digital camera (Industrial Digital Camera TOUPCAMTM U3CMOS10000KPA).

## 3. RESULTS AND DISCUSSION:

*Scutellaria stevenii* is a erosulate dwarf-shrub growing in tomillars and petrophytic steppes of the foothills, where it can perform the function of a dominant, and often determining the structure of phytocoenoses (Abdulganieva, 2013). In the spatial and ecological distribution, this species is mainly found to sloping calcareous gravelly and marl ecotopes. *S. stevenii* is morphologically close to the species *S. taurica* and different from it short tomentose pubescence of the stem and petioles. The upper side of leaves is rarely tomentose gray-green and densely white-tomentose with completely hidden veins in the underside. Leaf margins have

shorter and broader straight teeth (Komarov, 1954).

### 3.1. Latent and Pre-generative periods

In connection with the arisen difficulties of finding the seedlings in the natural environment, observation of this age was carried out in artificial conditions. **Seeds (se)** are small (2x1 mm), oval in shape, compressed laterally. Seed peel densely pubescent with short hairs due to the seeds are gray. Seed germination was determined on the seventh day, and it averaged 10%, which explains the difficulty of finding the seedlings in the natural phytocenosis. This low percent of germination can be attributed to the lack of endosperm in the seeds of the Lamiaceae family. The **seedlings (p)** have rounded cotyledons (at the time of opening 0.4 x 0.4 cm), are painted green. The development of the 2nd pair of leaves occurs at 4-5 days after planting in the soil. They, in contrast to the cotyledons, have a peristolped form with 3 lobes on each side (Figure 1).

**Figure 1.** Seedlings of *S. stevenii*.

In seedlings formed 1-5 leaves of similar shape. The emergence of seedlings in nature is timed to the end of February - March of the spring period or the end of September - October of the autumn period of germination.

In the case of normal development, by the end of the first month, the seedlings acquire the features of a **juvenile age (j)**. Their distinctive feature is the absence of cotyledons and the active appearance of leaves with 3 toothed lobes, which then die off successively, and well-marked scars remain in their place. The duration of this age from 2.5 to 3 months (Figure 2).

**Figure 2.** *S. stevenii* juvenile individuals.

Plants of **immature age (im)** are distinguished by the appearance of leaves with 4 toothed lobes on each side of the leaf blade (Figure 3). The position of the epicotyl and hypocotyl is typically perpendicular to the soil surface, but they can greatly change the angle of inclination due to the peculiarities of the microrelief of the territory. At immature age the individuals of *S. stevenii* leave for the 1st wintering period.

**Figure 3.** *S. stevenii* immature individual.

At 2-3 years of the life cycle of the plant enters a **virginal age (v)**, (Figure 4).

**Figure 4.** Virgin *S. stevenii*.

In this age, all the vegetative features of the adult plant are already formed: the leaves are ovate, along the edge are deeply crenate-toothed, with wide, straight, 5-7 teeth on each side. Lateral growth branch are develop at this age - usually after winter (less often summer) dormancy. The first leaves of lateral branches are morphologically similar to the leaves of a seedling or juvenile plant.

There are signs of polyvariant development of life cycle. Individuals growing on a horizontal surface of the relief go through 2 stages of morphogenesis: 1) primary shoot ( $p \rightarrow j \rightarrow im$ ); 2) the primary bush ( $v \rightarrow g_1 \rightarrow g_2 \rightarrow g_3 \rightarrow ss \rightarrow s$ ). With the growth of individuals on movable soils of the slopes, virginal plants form different lengths (from 5-30 cm) xylorrhizoma, on which developing secondary bushes. In this type of life cycle, an individual has 3 stages of development: 1) primary shoot ( $p \rightarrow j \rightarrow im$ ); 2) primary bush ( $v$ ), 3) secondary bush ( $g_1 \rightarrow g_2 \rightarrow g_3 \rightarrow ss \rightarrow s$ ), resulting from the destruction of xylorrhizoma between primary and secondary bushes (Figure 5).

**Figure 5.** *S. stevenii* life cycle scheme  
1 – primary shoot; 2 – primary bush; 3 – partial bush.

The formation of this kind of rhizomes and secondary bushes provides a more vigorous fixation plant in the soil, the conquest of free

space. It compensates for the almost complete absence of sexual reproduction associated with the mass death of seedlings in a natural ecotope.

The general scheme of development of the pregenerative stage is shown in Figure 6, 7.

**Figure 6.** The scheme of the pregenerative period *S. stevenii*. a – seedling; b – juvenile plant; c – immature; d, e – virginal.

**Figure 7.** Variants of development of *S. stevenii* virginal individuals. a - formation of partial bushes on xylorrhizoma; b - virginal individual, preserving the structure of the primary bush.

### 3.2. Generative period

**Young generative plants ( $g_1$ )** are characterized by such an important feature as the loss of the connection of the parent plant with young bushes (particulas) that were formed in the virginal period of the life cycle.  $G_1$  usually has 2-3 woody branches of renewal, which can form 1-2 generative shoots (second-order growth axis). After flowering, the grassy part of generative shoots dies, and their woody bases begin to branch, giving the 3rd order growth axes.

*S. stevenii* generative shoots are monocyclic, and by the next spring, they die entirely until the lateral shoot but remain in contact with the parent plant. Therefore, in  $g_1$  individuals, shoots of the 2nd and 3rd orders remain capable of flowering, but the flowering shoots number is small (1-3). The flowers number in the inflorescence is 4-7. The main root is thickened, and the first signs of partitioning are noted in the anatomical structure. A large number of adventitious roots are formed. The root systems of young bushes are intensively developed, creating the secondary root system. The generative shoots formation and their transition to flowering in young bushes occur 1-2 years later than the primary individual. The duration of this age phase is 2-3 years (Figure 8).

**Figure 8.** Young generative individual.

**Mature generative (middle-aged) individuals ( $g_2$ )** are represented by a compact dwarf-shrub, composed of 18–20 mixed-age renewal growth axes, of which 1/3 (sometimes 1/2) are represented by generative shoots with 9–11 flowers. The lower parts of the perennial shoots begin to form the plagiotropic part, but at the same time, the compactness of the general structure of the dwarf-shrub is preserved. The function of the plagiotropic part is provided by dwarf-shrub regeneration and construction of the new above-ground growth axes. The fourth growth axes begin to appear. Some of the second-order shoots, in the basal part, acquires an oblique orthotropic position. On this part, a large number of renewal buds appear, from which can develop generative shoots or new renewal axes. The observed anatomical structure of the root shows the beginning of the particleon process in the mature generative plant. In this age, phase plant remains 2-4 years (Figure 9).

**Figure 9.** Mature generative (middle-aged) individual.

**Older generative plants ( $g_3$ )** are generally losing dwarf-shrub. At the base of vegetative and generative shoots, there is a distinctly pronounced plagiotropic part; therefore, spatially shoots acquire an ascending structure. The number of generative shoots decreases (less than 1/4 of the total), and the number of dead shoots of previous years increases, especially in the central part of the caudex. Also, the number of flowers in the inflorescence is reduced to 5-7. The degree of branching decreases only occasionally shoots of the 4th order of branching occur. The growth of shoots occurs mostly on the periphery of the dwarf-shrub. The bush becomes less dense, the main root twists along the central axis. In the root, anatomical partition processes continue. In this age phase, the plant remains 2-4 years (Figure 10).

**Figure 10.** Older generative plants individual.

In **sub-senile plants (ss)**, primary growth axes are intensively dying. Plant height is 15–20 cm. In this phase, dwarf-shrub is preserved by 4–6 principal axes along the periphery of the bush, branching only in the upper part (3–4 shoots). There are 1-3 generative shoots; buds contain no more than 2-3 flowers. The adventitious roots do not develop, which reduces the ability of reproduction of the new lateral roots. The particleoning process in the anatomical structure of the primary root is more progressive. The

duration of this age phase is 1-2 years (Figure 11).

**Figure 11.** Sub-senile individual.

In individuals of the **senile age (s)**, generative shoots are not formed. In this phase, processes of the elimination of primary aerial axes and lateral roots increase. A perennial woody base, up to 3-5 cm in diameter, is formed from the basal parts of dead shoots. The height of the aboveground portion is 8-12 cm. The size of the leaf blade is significantly reduced, but the number of teeth (5-7 tooth), which is typical for adult generative plants, remains the same (Figure 12). The duration of this age phase is 1 year.

**Figure 12.** Senile individual.

### 3.3. The anatomical structure of the stem and root.

The lower ligneous part of the generative shoot is covered with secondary dermal tissue - periderm. Phellem (cork cells) has longitudinal gaps and consists of 3-4 layers of dead cells. Under periderm, there are 5-6 layers of parenchymal cells of the cortex. Phloem with poorly developed mechanical tissue surrounds the xylem in a continuous layer. The conducting elements of xylem are represented by radial rows of vessels separated by thin medullary rays and xylem fibers. In the center - the pith with a well-

defined perimedullary zone, including elements of the primary xylem (Figure 13).

**Figure 13.** A – cross-section of the generative shoot of *S. stevenii*. sx – secondary xylem; cm – cambium; c – core, px – primary xylem; ppc – parenchyma of the primary cortex; pzc – perimedullary zone of the core; pr – periderm; fl – phloem, (15x20).

The main root is covered with a multilayer periderm of subepidermal origin, (Figure 14).

**Figure 14.** Cross-section of the main root of the generative individual *S. stevenii*. sx-secondary xylem; sfl – secondary phloem; cm – cambium; pc – primary cortex; px – primary xylem; pr – parenchymal ray; p – periderm (15x20).

The outer layers of the cork are formed of 3-6 rows of cells. Under the periderm, there are remnants of the cortex, formed by thin-walled cells elongated in the tangential direction (5-7 rows). After the inner layer of the cortex is functioning phloem. Narrow single-row rays

separate the xylem vessels in the radial direction. Between the conducting elements are located with non-woody fibers of the libriform

In the anatomical structure of the root of generative plants, signs of partition were found, the initial stages of which can be observed at 5-7 years of age in young generative individuals. In this age, the central cylinder in the cross-section becomes asymmetric, acquiring lobed outlines (Figure 15, A). The processes of xylem separation continue intensively along with the radial rays, and in the old generative individuals, they reach the middle of the stele. (Figure 15, B). The distance between the xylem segments is filled with parenchymal tissue. In some cases, the xylem is completely separating, forming small islands surrounded by parenchymal tissue (Figure 15, D). The processes of destruction of living tissues begin in the center of the cylinder and continue in the centrifugal direction, capturing the wood parenchyma and the parenchyma of radial rays. Dead tissue areas are don't coloring (Figure 15, C, E).

**Figure 15.** Anatomical features of root (A-E) and shoot (F) *S. stevenii* partition, (15x40).

Particle starts as a result of the spreading of traces of dead shoots to the root collar and further to the taproot. Partition of the shoot is visible in Figure 15 (F). The abundance of mechanical elements in the wood of the root and the long-term functioning of the growth axes determine the incomplete, morphologically unexpressed particularization, mainly limited by the root neck area and the basal part of the main root.

#### 4. CONCLUSIONS:

The leaf morphology and the teeth number of *S. stevenii* leaf blade are the main features of differentiation the preregenerative

period into 5 age states; the three age states ( $g_1$ ,  $g_2$  and  $g_3$ ) of generative period are differentiated by habitus, branch axes of 2-4th orders, the ratio of generative and vegetative shoots, and the number of flowers. In the senile period included two age-related states (s, ss) are differentiate according to the intensity of branching, partition and dying of the aboveground skeletal axes; the early stages of shrubs partition are clearly correspond to the anatomical features. The vegetative reproduction in the preregenerative period is a compensatory adaptation respond to the high flexibility of seedlings in natural phytocoenoses. This indicates a high ecological and morphological plasticity of the species due to a change in realization of ontogenesis. The primary taxonomic criteria for intraspecific differences between *S. stevenii* and *S. orientalis* are the presence of xylorizome, vegetative reproduction at virgin age and differences in the teeth number of leaf margin.

## RESUMO

Globalmente, as doenças cardiovasculares (DCV) são a principal causa de morte. Prevê-se que 23,6 milhões de pessoas morrerão em 2030 tendo como causa principalmente derrames e ataques cardíacos. Este estudo teve como objetivo investigar o novo tratamento da cardiomiopatia, uma doença cardiovascular que dificulta o fornecimento de sangue do coração para o corpo e pode causar insuficiência cardíaca. Embora o tratamento tradicional se concentre na reabilitação cardíaca, incluindo exercícios de aconselhamento e prescrições de estilo de vida, cirurgia na artéria coronária e medicamentos para aumentar o fluxo sanguíneo, o uso de células terapêuticas é uma nova forma para lidar com doenças cardiovasculares e infarto do coração. Pretende substituir efetivamente ou regenerar as células cardíacas mortas ou danificadas, de forma eficaz, como a principal vantagem deste tratamento. O uso de método alternativo para tratar as doenças cardiovasculares tem alto valor potencial, conforme encontrado no método de imunoterapia através do uso de "macrófagos regenerativos". Trata-se de um estudo qualitativo de pesquisa de relato de caso em que fornece uma exploração do fenômeno ou oportunidade de compartilhar esforços para intervir anteriormente na saúde de um único paciente com recursos de saúde não relatados. O resultado deste estudo mostrou que um homem de 71 anos foi hospitalizado no Hospital Central do Exército de Gatot Soebroto, em Jacarta, na Indonésia, pelo diagnóstico de doença arterial coronariana. Ele apresentou tosse crônica e edema periférico. Negava síncope, dispnéia, náusea, vômito e diaforese. A aplicação da ecocardiografia referente ao tratamento anterior indicou disfunção diastólica, hipocinesia do ventrículo esquerdo e hipertrofia ventricular esquerda com 44% de baixa ejeção na fração. Após a vacinação da terapia com Macrófagos Regenerativos (ReM), foram observadas melhorias significativas nos parâmetros ecocardiográficos, com cinética normal, fração de ejeção melhorada e disfunção diastólica que aumentou para 56%. Significativamente, os macrófagos regenerativos podem ser uma opção de imunoterapia em pacientes com cardiomiopatias com baixo risco de tratamento eficaz.

**Palavras-chave:** *Macrófagos Regenerativos, Cardiomiopatia, Ecocardiografia, Fração de Ejeção.*

## ABSTRACT

Globally, cardiovascular diseases (CVD) are the number one cause of death. It is predicted that 23.6 million people will die from it by 2030, mainly caused by strokes and heart attacks. This study aimed to investigate the new treatment of cardiomyopathy, a cardiovascular disease that hinders blood supply from the heart to the body and can cause heart failure. While the traditional treatment focus on cardiac rehabilitation, including lifestyle counseling and prescription exercise, surgery on coronary bypass artery, and medication of increasing the flow of blood, the use of therapeutic cells is a new way to deal with cardiovascular diseases and heart infarction. It intends to effectively replace or regenerate dead or damaged heart cells, as the main advantage of this treatment. The use of alternative methods to treat cardiovascular diseases has high potential value, as found in the immunotherapy method through the use of "regenerative macrophages." This study is a qualitative case report research study which provides an exploration of phenomenon or opportunity of sharing efforts to intervene single patient's health with unreported health features previously. The result of this study showed that a 71 years old man was hospitalized in Gatot Soebroto Central Army Hospital Jakarta, Indonesia, by the diagnosis of coronary artery disease. He presented for chronic cough and peripheral edema. He denied syncope, dyspnea, nausea, vomiting, and diaphoresis. The application of echocardiography regarding the previous treatment indicated diastolic dysfunction, left ventricle hypokinesis and left ventricular hypertrophy with 44% of low ejection on the fraction. After the vaccines of Regenerative Macrophages (ReM) therapy were given to the patient, significant improvements in the echocardiography parameters were observed, with normal kinetics, improved ejection fraction, and diastolic dysfunction increased to 56%. Significantly, regenerative macrophages could be an option of immunotherapy in patients with cardiomyopathies with low risk of effective treatment further.

## 1. INTRODUCTION:

As the leading cause in over budgeting for universal coverage in terms of health blanket insurance in developing countries, cardiovascular disease (CVD) gets its vital concern for years. Its symptoms appear mostly at middle age along with pathological features called atherosclerosis. Acute coronary and cerebrovascular events frequently suddenly occur, and are often fatal before medical care can be given. Modification of treatment risk factors has been shown to reduce mortality and morbidity in people with diagnosed and undiagnosed cardiovascular disease (CVD). Cardiovascular disease is characterized by its high prevalence as the leading cause of early morbidity in the population (Apetrei-Corduneau, Fildan, Radu, Statescu, Nemteanu, Lupusoru., 2020., Diaconu, 2019).

The devitalizing impediment found in CVD is usually seen in middle-aged or older adults and women. However, atherosclerosis, the principal pathological process leading to coronary artery disease, cerebral artery disease, and peripheral artery disease, begins early in life and progresses gradually through adolescence and early adulthood (Berenson *et al.*, 1989., Zieske, Malcom, & Strong, 2002., Mendis *et al.*, 2005).

Several factors cause an increased risk of the threat of someone suffering from cardiovascular disease, one of which is the rate of development of atherosclerosis. It is exacerbated by smoking habits, improper dietary patterns without being balanced with physical activity, diabetes, dyslipidemia, and hypertension which are risk factors as triggers for the blockage of blood flow, and narrowing of blood vessels because of continued effects of the development of atherosclerosis which can trigger severe illness such as; myocardial infarction, stroke, transient cerebral ischemic attacks, and angina.

There are some ways of therapy to halt cerebral, peripheral vascular, and coronary events without putting aside aspects of intensity and particular aversive action to predict any risks of vascular features as the guidance leading for decision.

The most current treatment applied for most patients with cardiovascular diseases is by having healthy living behavior continued by taking medicine when needed to reduce the occurrence of strokes and heart attacks which directly affect

the reduction in mortality, morbidity, and premature disability. Nearly most people are unaware or aware of their status against potential CVD attacks. With self-screening, it will be able to detect several risk factors that arise, such as blood pressure, blood glucose, and blood lipids (Tunstall-Pedoe, 2003). By the result of screening for the risk of their status in CVD, it can be used as a guide for further action, whether in the form of a healthy lifestyle program related to the type of food intake, or physical exercise that can cure patients at an affordable cost. (World Health Organization, 2003).

The pattern of prevention of CVD by being associated with existing risk factors will be very significant in the accuracy of the diagnosis and clinical action taken on patients. Other considerations, such as the type of food intake and physical body processing, should also not be ruled out because it is related to the type, dose, and time of medication given to patients for continued risk control. Efficiency and effectiveness in managing patients become a necessity amid limited resources through a risk stratification approach (Integrated cardiovascular management, 2002). Administration of drugs in patients with diastolic blood pressure above 90 mmHg, systolic levels above 150 mmHg, and blood cholesterol levels above 5.0 mmol/l can reduce the risk of cardiovascular disease by one third to a quarter (Lewington., & Clarke, 2005; Baigent *et al.*, 2005., Turnbull, 2003., Sever, 2003., Lewington *et al.*, 2002., Lawes *et al.*, 2003., & LaRosa, He, Vupputuri, 1999). To anticipate cardiovascular disease contributed by blood compulsion is in proceeding toward of overall risk of 5-8 mmHg (diastolic), 10-15 mmHg (systolic) and included blood cholesterol at approximately 20% integrated medication with antihypertensive and statins, then cardiovascular disease morbidity and mortality would be reduced by up to 50% (Wald ., & Law, 2003). People at very high CVD risk would bring more positive and significant results in the perspective of total circumstances as the declining risk of CVD toward higher diagnostic risk (MacMahon., & Rodgers, 1993).

However, the disadvantages of this regular or traditional treatment are at the cost of medicines. It is a significant component of total preventive health care costs, and particularly relevant to base drug treatment decisions on an individual's risk level, and not on arbitrary criteria, such as the ability to pay, or on comprehensive

preventive strategies. Also, the cumulative risk of CVD, which uses risk scoring methods, has been shown to be both expensive and less effective.

For people or patients who have a history or record of transient ischemic attacks, myocardial infarction, a stroke, which generally begins with atherosclerosis symptoms, it becomes an essential record in efforts to obtain other treatment methods. This is crucial because there is a very high risk of coronary, peripheral, and cerebral artery stability. The patient's history of the tendency of CVD symptoms will affect the type of care given to reduce mortality and or the cost of care for patients who recover. Stratification risk charts are unnecessary to arrive at treatment decisions for these categories of patients. They require another option of medical treatment, which not only to have healthy food but also an intervention in how to stop smoking, achieve ideal weight and have regular body exercise, which is highly cost and consuming much time (World Health Organization, 2003; Tunstall-Pedoe, 2003).

Therefore, this study aimed to investigate the new treatment of cardiovascular disease as occurred in cardiomyopathy in a less expensive and complicated procedure to reduce the risk of death to respond to the patients' needs for medication.

## 2. REVIEW OF LITERATURE:

### 2.1. Macrophages

Macrophages were first discovered by Ilya Metchnikoff in the late 19th century and are conserved phagocytes evolutionary that evolved more than 500 million years ago as the system against occurred injury (Yonggang, Merry., *et al.*, 2018). They belong to white blood cell digests cancer cells, foreign substances, cellular debris, and microbes, and any other substances that have specific proteins for the body's health on its surface, namely as phagocytosis.

They are found basically in all tissues by amoeboid movements to patrol for potential pathogens. The forms of these macrophages are varied (with various names) along the body (for example, Kupffer cells, microglia, histiocytes, alveolar macrophages) as part of the system in mononuclear phagocyte. They keep up their essential role as the protection by the mechanism of defense both in innate immunity and adaptive immunity by involving other immune cells such as lymphocytes (Yonggang, Merry., *et al.*, 2018., Gordon, 2007., Epelman, Lavine, Randolph, 2014).

In addition, to improve stimulation and inflammation towards the immune system, they can be functioned as reducing reactions on immunity and anti-inflammatory by releasing cytokines Ben-Mordechai., Palevski., Glucksan-Galnoy., Elron-Gross., Margalit., Leor, 2015). Macrophages which can lead into inflammation are labeled as M1, while others heading to declining on inflammation and supporting the repair on tissues are tagged as M2.10 The main difference between two of them are found in their metabolism where M1 includes unique ability to metabolize arginine into nitric oxide "killer" molecules. At the same time, M2 can metabolize arginine into ornithine "repair" molecules (Gombozhapova, Rogovskaya, Shurupov., *et al.*, 2017., Martine., Sica, Mantovani., & Locati, 2008).

### 2.2. Physical Examination

It is exposed that around 21 micrometers (0,00083 in) in the diameter of human macrophages are resulted by the categorization of monocytes' tissue (Gombozhapova, Rogovskaya, Shurupov., *et al.*, 2017., Martinez., Sica, Mantovani., & Locati, 2008). By applying cytometry flow or immune histochemical staining with a particular expression of their proteins such as lysozyme M, MAC-1 / MAC-3, and CD68, CD14, CD40, CD11b, CD64, F4 / 80 (rat) / EMR1 (human) (Pelegrin., & Surprenant, 2009). These characteristics are mentioned in table 1 (Bai, Adriani, Dang., *et al.*, 2009., Colin, Chinetti-Gbaugidi., & Staels, 2014). M2a and M2c macrophages are mainly undertaking to coordinate the response of adaptive, while M2b macrophages suppress (inflammation, fibrosis) and tissue remodeling (Lindset., & Saucerman, 2016).

### 2.3. Parameters Checked

The parameter or macrophages are the total number of viable cells, proportion of viable cells, proportion of TLR 2- Positive cells, the proportion of CD 274 positive cells, the balance of CD 80 positive cells, the proportion of CD11c positive cells. The required review result of each: the total number of viable cells  $\geq 1 \times 10^6$  cells proportion of viable cells  $> 50\%$  proportion of TLR 2- Positive cells  $\leq 40\%$ , the proportion of CD 274 positive cells  $\geq 50\%$ , the proportion of CD 80 positive cells  $\leq 75\%$ , the proportion of CD11c positive cells  $\geq 90\%$ .

Cardiomyopathy patient that refused CABG and PCI come to cell cure. The doctor that cell-cure qualified takes a medical history and do

a physical examination. Physical examination consists of head to toe checking and vital sign. After that, the patient received a series of examinations in the laboratory, such as complete blood count, liver function, renal function, and immunoserology (HIV, Hep B, and Hep C). After that, the cell cure takes whole blood with two techniques. First, it was done manually (without the device). The whole blood had been taken as much as 9 cc x 23 tubes. Total whole blood is 207 cc. Second, it was used leukapheresis to get monocyte from the leukocyte. After that, it was processed in a clean-room. To get the monocyte cell, a labeling system was used with a flow cytometer. Similar things to the monocyte that manipulated become macrophages were done. It was also used as a labeling system with flow cytometry until it gets macrophages that were wanted.

In contrary to recently used treatments, Therapeutic methods immunotherapy have the significant possibility to encourage and promote endogenous mechanisms of cardiac repair and give the main element for full regeneration of damaged heart tissue (Lemcke., Voronina., Steinhoff., *et al.*, 2018).

Most of the macrophages are located in the strategic point where the accumulation of microbial invasion may take place along together in the mononuclear phagocyte system. Each type of macrophage, determined by its location, has a specific name (Kara, Spiller., & Timothy, 2017). Macrophages can express the function of paracrine within an organ that is specific to the role of that organ. The viable cells of ReM that needed to stimulate a robust inflammation immune response is  $\geq 1 \times 10^6$  cells). ReM was administrated by intravenous therapy (IV) (Figure 1).

Macrophages are widely distributed in the human body. Macrophages play a role in the inflammatory process as the body's reaction to foreign matter or microbes. In neoplastic growth, macrophages are found in the extracellular space. These macrophages in the extracellular space are known as tumor-associated macrophages (TAMs). For years it has been known that TAMs are the main cellular component of cancer in humans. However, it is still difficult to understand how the process and mechanism. Macrophages phagocytose pathogens, dead cells, and some elements in the matrix extracellular. Macrophages also function to regulate organ and homeostasis remodeling. During tissue regeneration or healing, macrophages stimulate angiogenesis and facilitate tissue remodeling by protease secreting

and growth factors. Macrophages in tissue can be identified by the expression of several markers; in humans, the marker is CD68. The majority of macrophages are in the area perivascular wound healing area

In some cases, the pathogenesis of cardiomyopathy remains unknown and thus is classified into idiopathic cardiomyopathy. Previously, ischemic cardiomyopathy was also included in the category of cardiomyopathy but the current consensus separates it into coronary heart disease. The causes of cardiomyopathy are various, but the most common is inherited genetic factors, both autosomal dominant and recessive, and related to sex chromosomes. Other causes include toxins related to alcohol use disorder, cocaine and amphetamine use disorder, or the use of chemotherapy drugs.

The patient wanted an advance therapy, but he refused coronary artery bypass graft (CABG). The doctors want to increase survival rate with gave especially regenerative macrophages vaccine therapy. After this intervention approach, the patient had been checked by echocardiography. The result was significantly changed and increased. Echocardiography showed diastolic dysfunction, left ventricular hypertrophy, ejection fraction, and normokinetic, from 44% became 56 %.

Macrophages can migrate out of the vascular system by crossing cell membranes from capillaries and entering the area between cells that are being targeted by pathogens. Neutrophils are the most efficient phagocytes followed by macrophages and can digest large amounts of bacteria or other cells. Binding of bacterial molecules to the surface receptors of macrophages triggers the process of swallowing and destroying bacteria through "respiratory attack", causing the release of reactive oxygen species (ROS). The pathogen also stimulates macrophages to produce chemokines, which call other phagocytic cells around the infected area to give influence on the development of chronic inflammatory diseases such as cardiomyopathy.

### 3. MATERIALS AND METHODS:

It is a qualitative case report research study where provides an exploration of phenomenon or opportunity of sharing efforts to intervene single patient's health with unreported health features previously. As a qualitative methodology, it encompasses a great deal more complexity and incorporates of data combined in creative ways. It provides richness and depth description that helps

to understand the situation and whether findings from the case are applicable of a report from a 71 years old man by the diagnosis of coronary artery disease as the sample to be reported. The patient presented for chronic cough and peripheral edema of left ventricular diastolic function.

His parents and/or relatives in this participant study were informed related to the nature of the study and signed a consent for taking part in the study. It was approved by the Ethics and Bioethics Committee of the National Health Ministry of Indonesia and according to Helsinki Declaration (1975).

#### 4. RESULTS AND DISCUSSIONS:

According to the survey in 2013 to 2016 by National Health and Nutrition Examination, the generality of cardiovascular diseases (CVD), adjusting stroke, coronary heart disease (CHD), hypertension, and heart failure (HF) in  $\geq 20$  years of age by category of adults is 48.0% (121.5 million in 2016) and uplifting with progressing age in both men and women. Using Healthcare Cost and Utilization Project (HCUP) data for cardiomyopathy in 2014, there were 16,000 hospitalizations in America. Its system to be not transparent and understudied as underlying the changes that occurred (Roytberg, Sharkhun, Platonova., & Stepanova, 2020).

It showed that cardiomyopathy became the main diagnosis of 966.000 cardiovascular diseases, mostly found. Data from the National Heart, Lung, and Blood Institute, sponsored by some institutions covering; Chicago Heart Association Detection Project in Industry, ARIC (Atherosclerosis Risk in Communities Study), and CHS (Cardiovascular Health Study) indicate that incidence of HF approaching population to 21 per 1000 after the age of 65 years old (Benjamin. *et al*, 2019).

The cells in heart muscle cells or myocardiocytes are muscle cells that form heart's muscle consisting of sarcomeres. They expose something in common as found in skeletal muscle cells that may have as many as four nucleus producing adenosine triphosphate quickly, making it very resistant to fatigue.

The necrosis in cardiomyocyte is caused by external factors of cells or tissues, such as infection, toxins, or trauma that result in irregular digestion of cell components. Cellular death due to necrosis does not follow the apoptotic signal transduction pathway; various activated receptors result in loss of cell membrane integrity and

uncontrolled release of cell death products into the extracellular space. This event triggers an inflammatory response in the surrounding tissue, attracting leukocytes and phagocytes that are close to killing death cells with phagocytosis. However, destructive microbial agents released by leukocytes will create additional damage to the surrounding tissue. This extra damage is excessively inhibiting the healing process. Thus, untreated necrosis results in piles of tissue and debris that decompose dead cells at or near the location of cell death.

Macrophages originate from monocytes found in the blood circulation, which become mature and differentiated then migrate to the tissue. They can be found in large numbers, especially in connective tissue, such as those connected to the digestive tract, in the lungs (in body fluids or alveoli), and along certain blood vessels in the liver such as Kupffer cells, and in the entire spleen where the cells are damaged blood is recycled out of the body. This type of macrophage is called a resident who is fully differentiated. They are an integral part of innate immune response and leads to the main interest of research scientifically. As the key to respond inflammation, macrophages perform antigens on the surface on their cell by major histocompatibility complex II (MHC II) that result in cellular debris on resorption, anti and pro factors on inflammatory, and formation of granule tissue. They could also function as healing and remodeling the cardiac through growth factors, apoptosis, proteases, and proliferation (Gombazhapova, Rogovskaya, Shurupov., *et al*, 2017., Yona, Kim, Wolf, Mildner, Varol, Breker., *et al*, 2013).

The plasticity of myocardial infarction in macrophages and monocytes' function plays an essential role to control cardiac remodeling, inflammation, and acute coronary healing (Furth., & Cohn, 1968., Takahashi, 1994., Yona, Kim, Wolf, Mildner, Varol, Breker., *et al*, 2013., Sica., & Mantovani, 2012).

A 71 years old man was taken to Gatot Soebroto Central Army Hospital Jakarta, Indonesia, by the diagnosis of coronary artery disease. The patient presented for chronic cough and peripheral edema. He denied syncope, dyspnea, nausea, vomiting, and diaphoresis. His medical history was notable for hypertension and diabetes mellitus type II. On admission, the patient was afebrile; his heart rate was 86 beats per minute, respiratory rate was 20 breaths per minute, blood pressure was 140/90 mmHg, oxygen saturation was 98% on room air. He was alert and in no acute distress, without notable

jugular distension. Cardiac examination revealed normal S1 and S2, with no murmur or extra heart sounds. His lungs are clear to auscultation bilaterally. Peripheral edema was noted.

The patient performed a series of investigations covering; echocardiography, chest X-ray, and electrocardiography. Chest X-ray was abnormal with CTR 50% (Cardiothoracic ratio), fibrosis in right basal lung, without infiltrate, and haziness in the costophrenic angle, with differential diagnosis of pleuritis. The electrocardiogram showed multiple ventricular extrasystoles. The echocardiography performed diastolic dysfunction (impaired relaxation type), hypertrophy on left ventricular, and hypokinetic on the left ventricle with low ejection fraction 44% (Figure 1). The diagnosis of hypertrophic cardiomyopathy was established.

The patient refused the coronary artery bypass graft (CABG). Furthermore, the doctors want to increase survival rate with gave especially Regenerative Macrophages vaccines therapy. After this intervention approach, the patient had been checked by echocardiography. The result was significantly changed. Echocardiography showed left ventricular hypertrophy, normokinetic, diastolic dysfunction, and ejection fraction became 56 %.

In this case, the patient treated by the method of immunotherapy was chosen by regenerative macrophages of human origin from the patient. In regenerative macrophages of human origin vaccine therapy, blood's monocytes were split out from others' components and programmed as regenerative macrophages of human origin. The human macrophages cultures were established by treating peripheral blood monocytes and complete for four days.

The measurement of pulse wave Doppler sample volume on the transmittal inflow shows an E / A ratio, a marker of the function of the left ventricle of the heart. It represents the ratio of peak velocity blood flow from left ventricular relaxation in early diastole (the E wave) to peak velocity flow in late diastole caused by atrial contraction (the A wave), of less than 1, showing a grade 1 diastolic dysfunction (Figure 2).

Visualization of the left ventricle in PLAX, Mmode at the mitral tips level that works by transducing image marker directed toward the patient's right ear and the sound beam directed to the spine. Slight adjustments in angle and rotation maybe necessary to demonstrate all the structures for this view optimally, quantify LVEF with the Teicholz equation is 44%, with myocardial

thickening as measured by interventricular septum was 13.4 mm at diastolic and 16.6 mm at systolic and also 267 g/m<sup>2</sup> in LV mass (Figure 3).

Quantitative assessment of Right Ventricular function with Tricuspid Annular Plane Systolic Excursion (TAPE) was 23.7 mm, reveal the normal value of RV function (>20mm means RV EF >50%) (Figure 4). The left ventricular ejection fraction increased with the calculation of the Teicholz formula obtained by 56% (Figure 5).

By using RPMI-1640 (Lonza), adherent cells were accomplished with additives with 5% CO<sub>2</sub> at 37°C. The recombinant of human macrophage colony-stimulating factor (50 ng/mL) was used to gain M2-like macrophages and the deprivation conditions of its serum (autologous plasma in low percentage). PBS (Phosphate Buffer Saline) is used to have macrophages in four days, followed by EDTA (Lonza), washed with Triple Express Tripsine (Gibco), and counted in 4 days (Table 1). M2-like macrophages were generated and resuspended in 2 mL of 3x 10<sup>7</sup> sodium chloride 0.9% plus Albumin 20% and the end infused into IV of the patient. Therapeutic methods immunotherapy and their combination are the major promising strategies. The modes of immunotherapy were classified as conventional and rush immunotherapies. In contrast to currently applied treatments, immunotherapy has the potential to stimulate and support endogenous mechanisms of cardiac (Table 2).

## 5. CONCLUSIONS:

CVD is characterized by its high prevalence as the leading cause of early morbidity in the population. The suffered patient with cardiomyopathy found no alternative for medication recovery performed positive progress on echocardiography and clinical after treated with immunotherapy by the Regenerative Macrophages vaccine. In some pathological conditions, it has the function to force tissue homeostasis and innate immunity. Macrophages degrade and ingest foreign materials, dead cells, and debris. They support homeostasis by responding to external and internal changes within the body. It is not only as phagocytes, but also repair functions, regulatory, and trophic.

## RESUMO

Uma das tarefas prioritárias para a indústria aeronáutica moderna é elevar a eficiência econômica das aeronaves. No contexto da solução deste problema, ao criar novas aeronaves, os materiais compostos de polímeros (PCM) são cada vez mais utilizados. É dada especial atenção aos elementos estruturais, cujos danos podem levar a diminuição da resistência geral da estrutura. Portanto, uma tarefa essencial no projeto, manutenção e operação do teste é estudar o efeito de defeitos entre camadas na resistência e no comportamento das estruturas de PCM sob a influência de cargas instáveis. Este trabalho foi dedicado a análise numérica do comportamento de uma placa feita de material compósito de polímero (PCM) sob carga instável, considerando defeitos intercamadas de forma elíptica, bem como uma avaliação da resistência de uma embalagem compósita de acordo com várias fraturas critério. O problema foi resolvido pelo método dos elementos finitos usando o pacote de *software* LS-DYNA. Em seguida, utilizando o método de modelagem matemática, analisou-se a separação entre camadas de uma forma elíptica, que permitiu avaliar a resistência da placa e da fibra de acordo com os critérios de Hashin, Puck, Chang-Chang e LaRC03 e comparar os resultados. Verificou-se no estudo que os índices de falha e os fatores de segurança, obtidos através de vários critérios (Hashin e Chang-Chang), têm a mesma distribuição, desde a dependência do modo de fratura implementado (compressão da fibra na direção longitudinal) foi idêntico. Os materiais de análise podem ser levados em consideração ao desenvolver requisitos técnicos e montar estruturas de aeronaves.

**Palavras-chave:** *placa composta, critérios de falha em compósitos, defeito interlaminar, método dos elementos finitos (MEF), material compósito polimerico.*

## ABSTRACT

One of the priority tasks of the modern aviation industry is to increase the economic efficiency of aircrafts. In the context of solving this problem, when creating new aircrafts, polymer composite materials (PCM) are increasingly used. Particular attention is paid to structural elements, damage to which can lead to a decrease in the strength of an airframe as a whole. Therefore, an essential task in the design, maintenance, and operation of the test is to study the effect of interlayer defects on the strength and behavior of PCM structures under the influence of unsteady loads. This work is devoted to a numerical analysis of the behavior of a plate made of a polymer composite material (PCM) under unsteady load considering interlayer defects of an elliptical shape, as well as an assessment of the strength of a composite package according to various fracture criteria. The problem is solved by the finite element method using the LS-DYNA software package. Then, using the method of mathematical modeling, the interlayer separation of an elliptical shape was analyzed, which allowed to evaluate the strength of the plate and fiber according to the criteria of Hashin, Puck, Chang-Chang, and LaRC03 and

compare the results. It was found in the study, that the failure indices and safety factors, which were obtained using various criteria (Hashin and Chang-Chang), have the same distribution, since the dependence of the implemented fracture mode (fiber compression in the longitudinal direction) is identical. Analysis materials can be taken into account when developing technical requirements and assembling aircraft structures.

**Keywords:** *composite plate, composites failure criteria, interlaminar defect, finite element method (FEM), polymer composite material.*

---

## 1. INTRODUCTION

Appropriate calculations and full-scale tests must support the structural strength of the PCM in the aviation industry. Particular attention is given to the structural elements, damage which can lead to a decrease in airframe structural strength in general. The result of such damages may be interlayer defects such as bundles (Nia *et al.*, 2020; Shen *et al.*, 2020; Tian *et al.*, 2020).

Interlaminar defects can occur at various stages, both at the production stage and during operation. Among the main reasons that can cause defects, we can distinguish the following: a collision with a bird, hit stones on takeoff, non-localized dispersion of the engine rotor, hit fragments pneumatics, hit hail, collision when towing or steering with aerodrome infrastructure facilities, falling tool or replacement part (Koh and Madsen, 2018; Valverde *et al.*, 2020).

The resulting defects at selected non-destructive testing methods (including ultrasonic flaw detection, x-ray, current-vortex, optical holography, acoustic monitoring) are divided into undetectable, detectable with any form of control, reliably detected within several flights by technical personnel and evident to the crew (Miranda Guedes, 2019). The presence of defects in the structure of the PCM elements can lead to cracking of the binder, fiber destruction, and loss of strength of the composite packet (CP) (Kulkarni *et al.*, 2020). It follows that an essential task for the design, maintenance, and operation of the test is to study the influence of interlaminar defects on the strength and behavior of PCM constructions under the influence of unsteady loads (Ershova *et al.*, 2018; Medvedskiy *et al.*, 2019; Medvedsky *et al.*, 2019a; Medvedsky *et al.*, 2019b; Medvedsky *et al.*, 2019c; Medvedsky *et al.*, 2019d; Medvedsky *et al.*, 2019e). This paper shows the results of numerical simulation of the behavior of a rectangular plate made of a layered composite in the presence of interlayer defects of the bundle type. The impact of a spherical blast wave formed after the detonation of a point source is considered as an external non-stationary load. In solving the problem, we used the finite element method (FEM)

implemented in the LS-DYNA software package using an explicit time integration scheme for the complete system of FEM equations (Bento Rebelo and Cismaşiu, 2017; Trajkovski, 2017a; Trajkovski, 2017b; Erdik and Uçar, 2018; Teng, 2018; Bisyk *et al.*, 2019). The distribution of pressure on the outer surface of the plate, deflections in the zone of defects at different times were obtained, as well as the analysis of the operating stresses and deformations in the layers of the plate, and based on this analysis, the maximum failure indices and minimum safety factors in the most loaded layer were determined according to various failure criteria for composite materials (Chen *et al.*, 2020; Rena *et al.*, 2020). A comparison of the considered failure criteria for a point with a minimum safety factor is performed, and a graph of changes in the failure indices at various points in time is presented. A quantitative assessment of the degree of reduction of the minimum safety factor in the presence of multiple elliptic defects between the layers of the plate is made. The proposed method allows us to take into account the presence of interlayer defects of various shapes, sizes and layouts between the layers of the package under the action of a wide range of non-stationary loads: the action of pressure fields distributed according to different laws, the impact of a striker with different speed and energy, the action of acoustic and explosive waves generated by different sources, the impact of temperature fields.

The consideration of interlayer effects with allowance for temperature factors was considered. This work is devoted to the numerical analysis of the behavior of the plate of a polymer composite material (PCM) under unsteady load considering interlayer defects elliptical shape, as well as evaluating the strength of the composite package according to various failure criteria.

## 2. MATERIALS AND METHODS

The object of this research is a rectangular plate made of PCM length  $a = 500$  mm and a width  $b = 200$  mm (Figure 1). The plate is made of carbon fiber using autoclave technology based on

prepreg HexPly M21/34%/UD194/IMA (IMA carbon tape-based high-strength fiber HexTow IMA-12K and modified epoxy binder M21) manufactured by Hexcel Composites (USA). The thickness of the mono-layer is assumed to be equal to  $h = 0.184$  mm. Laying plate has the following scheme:  $[+45^\circ/-45^\circ/90^\circ/0^\circ/+45^\circ/-45^\circ/-45^\circ/+45^\circ/0^\circ/90^\circ/-45^\circ/+45^\circ]$  (total of 12 mono-layer, 2.208 mm total thickness of the package).

The problem is solved by the finite element method (FEM) in the software package LS-DYNA. Each mono-layer modeled a separate set of finite elements with the wording "16: Fully integrated shell element" and property "COMPOSITE". It is assumed that between all layers, there are defects in the form of interlaminar delamination of elliptical shape with axes of 60 and 40 mm. The layers, except for the defect zones, are connected by a glue contact "Automatic One-Way Surface to Surface Tiebreak". The "Automatic Surface to Surface" contact is taken into account between defects.

As an external unsteady load, an explosive impact with a spherical blast wave is used, which is modeled using the "Load Blast Enhanced" function based on the Kingery-Bulmash model (Le Blanc *et al.*, 2005; Tabatabaei and Volz, 2012; Schwer *et al.*, 2015). The epicenter of the explosion is located above the defects at a distance of 300 mm, and the detonation energy is  $E = 33.47$  kJ. As boundary conditions, the hinge support along the long edges of the plate is used. To assess the strength of a PCM plate, the following failure criteria are used to evaluate the strength of the matrix and the fiber separately: Hashin (1980), Puck (Puck and Schurmann, 1998), Chang and Chang (1987), LaRC03 (Sebaey *et al.*, 2011; Muizemnek and Kartashova, 2017). Appropriate depending is shown below. Criteria Hashin. Fiber strength for plane stress state is determined by the following Equations (1)-(2).

The strength of the matrix (Equations 3-4), where  $f_f$  – fiber failure index,  $f_m$  – matrix failure Index,  $\sigma_1$  – normal stress acting in the longitudinal direction,  $\sigma_2$  – normal stress acting in the lateral direction,  $\tau_{12}$  – shear stress acting in the plane,  $X_T$  – tensile strength in the longitudinal direction at a stretching,  $X_C$  – tensile strength in the longitudinal direction at a compression,  $Y_T$  – tensile strength in the transverse direction at a stretching,  $Y_C$  – tensile strength in the transverse direction under compression,  $S_{12}$  – shear strength in the plane. Failure occurs when one of the Equations (1)-(4) becomes equal to unity. Hashin failure index can be written as (Equation 5).

2. Criterion Puck. Fiber strength is determined by the following Equations (6)-(7). The strength of the matrix (Equations 8-13), where (Equations 12-13),  $f_{mA}$ ,  $f_{mB}$ ,  $f_{mC}$  – form of failure of the matrix. For carbon fiber reinforced plastics  $p_{12}^{(+)} = 0.3$ ,  $p_{12}^{(-)} = 0.35$ ,  $p_{22}^{(+)} = p_{22}^{(-)} = 0.25-0.3$ .

3. Criterion Chang-Chang. Strength fibers for plane stress state are determined by the following Equations (14)-(18). Fiber strength was determined using Equations (14), (15). The strength of the matrix was determined using Equations (16)-(18), where  $\beta$  – taken equal to 0.1.

4. Criterion LaRC03 (Chen *et al.*, 2018) Equations (19)-(25), where  $\varepsilon_1$  – the deformation is exerted in the longitudinal direction by stretching;  $\varepsilon_1^T$  – limiting deformation in the longitudinal direction at a stretching,  $\sigma_{22}^m$ ,  $\tau_{12}^m$  – stresses in areas of misalignment,  $\eta^L$  – longitudinal friction coefficient,  $Y_{is}^T$ ,  $S_{is}^L$  – the limits of local strength,  $g$ ,  $(G_{IC}/G_{IIC})$  – fracture stiffness coefficient,  $\tau_{eff}^T$ ,  $\tau_{eff}^L$  – effective shear stress in compression of the matrix calculated based on the Mohr-Coulomb criterion, which binds effective shear stress in the disk Mora failure plane (Equation 26), where  $\alpha_0 = 53$  – fracture angle.

Material mono-layer has the following mechanical characteristics:  $X_T = 2830$  MPa,  $X_C = 1500$  MPa,  $Y_T = 54$  MPa,  $Y_C = 271$  MPa,  $S_{12} = 96$  MPa,  $E_1 = 178$  GPa,  $E_2 = 8.6$  GPa,  $G = 3.0$  GPa,  $\mu_{12} = 0.32$ ,  $\rho = 1580$  kg / m<sup>3</sup>. Here  $\mu_{12}$  – Poisson ratio, which characterizes the lateral contraction in the longitudinal direction,  $G$  – shear modulus in the plane of the sheet,  $\rho$  – density,  $E_1$  – elasticity module in the longitudinal direction,  $E_2$  – modulus of elasticity in the transverse direction. Characteristics mono-layer received PKM manufacturer experimentally according to European standards EN samples for RTD mode (Room Temperature Dry): normal temperature +23 °C and the humidity – in the delivery state (Antufev *et al.*, 2019; Kuznetsova and Rabinskiy, 2019).

### 3. RESULTS AND DISCUSSION:

Figure 2 shows the variation of the external pressure on the surface of the plate in the center location of the defects as a result of the detonation wave. Figures 3-4 shows the stress distribution in the longitudinal direction and shear stresses in the layer No. 10 (90°) at a time 0.59 ms in cases of presence and absence of defects between the layers. Figures 5-7 show the distribution of safety factors in layer 10 (90°) at the time of 0.59 m s for

cases of presence and absence of defects between layers according to various failure criteria. Figure 8 shows the distribution of pressure from the blast wave action on the surface of the plate at a time 0.59 ms. Figures 9-10 show displacement along the major axis of the defect in the layer No. 10 at different time points for the plate in the presence and absence of defects, respectively. Figures 9-10 show that for layer 10, the maximum displacement values differ slightly, but the behavior is different. This is due to the presence of defects between layers. Figure 11 shows the variation of failure index at the point with a minimum safety factor for any failure criteria.

Thus, from Figures 3-7, it is seen that in case of a defect, the maximum-acting guides longitudinal stresses above about 1.68 times compared with the case of absence of defects. Analysis of the distribution failure indexes and safety factors obtained by different failure criteria showed that criteria Hashin and Chang-Chang have the same distribution because the dependence of the realized form of destruction (fiber compression in the longitudinal direction) is the same. The minimum safety factor was calculated from LaRC03 criterion (" $\eta = 0.87$ ") decrease in strength of the structure in case of the presence of defects LaRC03 criterion is 2.46 times.

#### 4. CONCLUSIONS:

Thus, the behavior of a laminate plate made of a polymer composite material under non-stationary load taking into account interlayer defects of an elliptical shape was studied, as well as the strength of the composite package according to various fracture criteria was assessed. The pressure distribution on the outer surface of the plate under the influence of an air blast wave is determined. The deflections of the plate along the defect are also determined in the presence and absence of interlayer defects. The analysis of these dependencies shows a difference in the behavior of the plate in the defect zone. The dependences of the failure indices on the considered failure criteria at various moments in time are determined. An analysis of distribution failure indices and safety factors obtained using different failure criteria showed that the Hashin and Chang-Chang criteria have the same distribution since the dependence of the realized fracture shape (longitudinal compression of the fiber) is the same. For the design under consideration, the presence of a defect reduces the strength by 2.46 times, the minimum safety factor is implemented using the LaRC03 criterion

and is 0.87. The results of the analysis can be taken into account when developing technical requirements and assembling the structures of an aircraft including when exposed to temperature fields.

#### 5. ACKNOWLEDGMENTS:

The work was conducted at the Moscow Aviation Institute with financial support from the Russian Foundation for Basic Research, project No. 18-08-01153.

## INSTRUCTIONS FOR AUTHORS

We ask authors always to visit the online instructions for the use of the latest instructions available. Manuscripts must be submitted using the template available on the Journal's website.

## PREPARATION OF MANUSCRIPTS

1. PREPARATION OF MANUSCRIPTS
2. THE FIRST PAGE OF THE MATERIAL
3. THE CENTRAL TEXT PART OF THE MATERIAL
4. GUIDELINES FOR REFERENCES
5. FIGURES
6. TABLES
7. MATHEMATICAL EXPRESSIONS
8. SUPPLEMENTARY MATERIAL

---

1. PREPARATION OF MANUSCRIPTS (TEMPLATE):

Please, observe the following points in preparing manuscripts. Papers not conforming strictly to these instructions may be returned to their authors for appropriate revision or may be delayed in the review process.

**Readability:** Manuscripts should be written in clear, concise, and grammatically correct English (British or American English throughout). The editors can not undertake wholesale revisions of poorly written papers. Every paper must be free of unnecessary jargon and readable by any specialist of the related field. The abstract should be written in an explanatory style that will be comprehensible also to readers who are not experts in the subject matter.

**General format:** The complete paper has to be written, preferably in Rich Text Format either in an MS-Word (.doc) or a Br.Office (.odt) compatible file. Page size: A4, margins: 2 cm on each side, line spacing: single, font type: Arial. Please leave headers and footers unchanged, since the editors should fill it. Please check guidelines for accurate information based on all different categories (review articles, technical notes, etc.) available. A single file of the whole manuscript should then be submitted through TQJ's email (journal.tq@gmail.com). The Journal no longer accepts submissions in any other form.

The order of the material should be as follows: Title, Author(s), Abstract, Keywords, Main text (Introduction, Review of Literature, Definitions (if any), Materials and Methods, Results, Discussion), Acknowledgements (if any), References, Appendix (if any). This structure of the main text is not obligatory, but the paper must be logically presented. Footnotes should be avoided. The main text must be written with font size 11, Arial, justify. Within each main section, three levels of subheadings are available, and the titles must be bold, bold, and italic, italic, respectively.

The manuscript should contain the whole text, figures, tables, and explanations according to the followings (we suggest using the template file):

---

2. THE FIRST PAGE OF THE MATERIAL SHOULD BE AS FOLLOWS:

**Title:** (both in Portuguese and English). The editors can provide the title in Portuguese for those whose Portuguese is not the first language. It should be brief and informative. The title should reflect

the essential aspects of the article, in a preferably concise form of not more than 100 characters and spaces. Font size 12, Arial, capital letters, center alignment.

**By-line:** Names (size 12, Arial, small capital) of the authors. No inclusion of scientific titles is necessary. In the case of two or more authors, place their names in the same row, separate them with a semicolon (;) and please indicate the corresponding author with \* in superscript. The corresponding author should be the one submitting the article online and an e-mail given (only one e-mail) below the addresses of all authors. Authors from different institutions must be labeled with numbers in superscript after the names. Addresses of the authors, phone, and fax number should also be given (size 10). Authors should be grouped by address.

**Abstract:** (both in Portuguese and English). The editors can provide the translation of the abstract to Portuguese for those whose Portuguese is not the first language. Required for all manuscripts in which the problem, the principal results, and conclusions are summarized. The abstract must be self-explanatory, preferably typed in one paragraph, and limited to max. 200 words. It should not contain formulas, references, or abbreviations. The name ABSTRACT should be written in capital letters, Arial, size 12, bold, left alignment. The abstract should be written font Arial, size 10, justify.

**Keywords:** (both in Portuguese and English. The editors can provide the keywords in Portuguese for those who Portuguese is not the first language). Keywords should not exceed five, not including items appearing in the title. The keywords should be supplied, indicating the scope of the paper. Size 10, italic, justify, only the word Keywords must be bold, left alignment.

The authors should include Abbreviations and Nomenclature listings when necessary.

---

### 3. THE CENTRAL TEXT PART OF THE MATERIAL SHOULD BE AS FOLLOWS:

The words Introduction, Materials, and Methods, Results and Discussion, Conclusion, Acknowledgements, and References must be written in capital letters, Arial, font size 12, left alignment, bold.

**Introduction:** The introduction must clearly state the problem, the reason for doing the work, the hypotheses or theoretical predictions under consideration, and the essential background. It should not contain equations or mathematical notation. A brief survey of the relevant literature so that a non-specialist reader could understand the significance of the presented results.

**Materials and Methods:** Provide sufficient details to permit repetition of the experimental work. The technical description of methods should be given when such methods are new.

**Results and Discussion:** Results should be presented concisely. Also, point out the significance of the results and place the results in the context of other work and theoretical background.

**Conclusion:** Summarize the data discussed in the Results and Discussion showing the relevance of the work and how different it is from other researches. Also, point out the benefits and improvements that can be observed to develop new scientific standards that can change something in the related field.

**Acknowledgments:** (if any) These should be placed in a separate paragraph at the end of the text, immediately before the list of references. It may include funding information too.

**References:** In the text, references should be cited in Harvard style (Author, year). Alternatively, the author's surname may be integrated into the text, followed by the year of publication in parentheses. Cite only essential resources, avoid citing unpublished material. References to papers "in press" must mean that the article has been accepted for publication, at the end of the paper list references alphabetically by the last name of the first author. Please, list only those references that are cited in the text and prepare this list as an automatically numbered list. The word References with size 12, Arial,

bold, capital letters, left alignment.

---

#### 4. GUIDELINES FOR REFERENCES:

- The Journal uses the APA (American Psychological Association) FORMAT CITATION as follows:

**Author's surname, initial(s).** **(Date Published).** **Title of Source.** **Location of publisher:**  
**publisher.** Retrieved from URL

##### Author Rules:

1. Initials are separated and ended by a period.

Examples: Goldani, E.  
De Boni, L.A.B.

2. Multiple authors are separated by commas and an ampersand.

Examples: Goldani, E. & De Boni, L.A.B.  
Goldani, E., De Boni, L.A.B. & Casanova, K.

3. Multiple authors with the same surname and initial: add their name in square brackets.

Example: Goldani, E. [Eduardo]

##### Date Rules:

1. Date refers to date of publishing
2. If the date is unknown 'n.d' is used in its place.

Example: De Boni, L.A.B (n.d)

##### Title Rules:

1. The format of this changes depending on what is being referenced

##### Publisher Rules:

1. If in the US: the city and two letter state code must be stated.

Examples: San Diego, CA  
Houston, TX  
New York, NY

2. If not in the US: the city and country must be stated.

Examples: Sydney, Australia  
Lisbon, Portugal  
Rome, Italy

**Retrieved from URL:** This is used if the source is an online source

## 5. FIGURES:

The number of pictures (including graphs, diagrams, etc.) should not exceed 10 and should be submitted either in JPG or PNG formats. All photographs, charts, and diagrams should be numbered consecutively (e.g., Figure 1) in the order in which they are referred in the text. Caption must appear below the figure (size 11, bold, italic) and should be sufficiently detailed to enable us to understand apart from the text. Explanation of lettering and symbols should be also given in the caption and only exceptionally in the figures. Figures should be of good quality and preferably in black and white. (Color figures will appear in the downloadable files, but all papers will be printed in black and white.) Scanned figures should be at a resolution of 800 dpi/bitmap for line graphs. Diagrams containing chemical structures should be of high graphical quality and always be of the same size so that they can be uniformly reduced. Figures should have a maximum width of one Journal column (8.5 cm) to be inserted on the body of the text so that they can be applied to the standards of the Journal. If the figures exceed 8.5 cm, they will be placed at the end of the article. Also, authors may be requested to submit each figure also as an image file in one of the following formats: jpg or png. For pictures, graphs, diagrams, tables, etc., identical to material already published in the literature, authors should seek permission for publication from the companies or scientific societies holding the copyrights and send it to the editors of TQ along with the final form of the manuscript.

---

## 6. TABLES:

Tables should be self-explanatory. They should be mentioned in the text, numbered consecutively (e.g., Table 1) and accompanied by title at the top (size 11, bold, italic). Please insert all the tables in the text, do not enclose huge tables which cannot be fit within the page margins.

---

## 7. MATHEMATICAL EXPRESSIONS:

In general, minimize unusual typographical requirements, use solidus, built-up fractions. Avoid lengthy equations that will take several lines (possibly by defining terms of the equation in separate displays). For drawing equations, please use the Equation Editor of Word, if possible. Make subscripts and superscripts clear. Display only those mathematical expressions that must be numbered for later reference or that need to be emphasized. Number displayed equations consecutively throughout the paper. The numbers should be placed in parentheses to the right of the equation, e.g. (Eq. 1).

---

## 8. SUPPLEMENTARY MATERIAL:

Any Supplementary material (other figures, tables, diagrams, etc.) should be placed at the end of the manuscript and indicated as such. A single.PDF - document, including the supplementary material, should be submitted.

**Editors, at any time of the editing process, may ask authors to split off part of the manuscript, presenting it as supplementary material.**

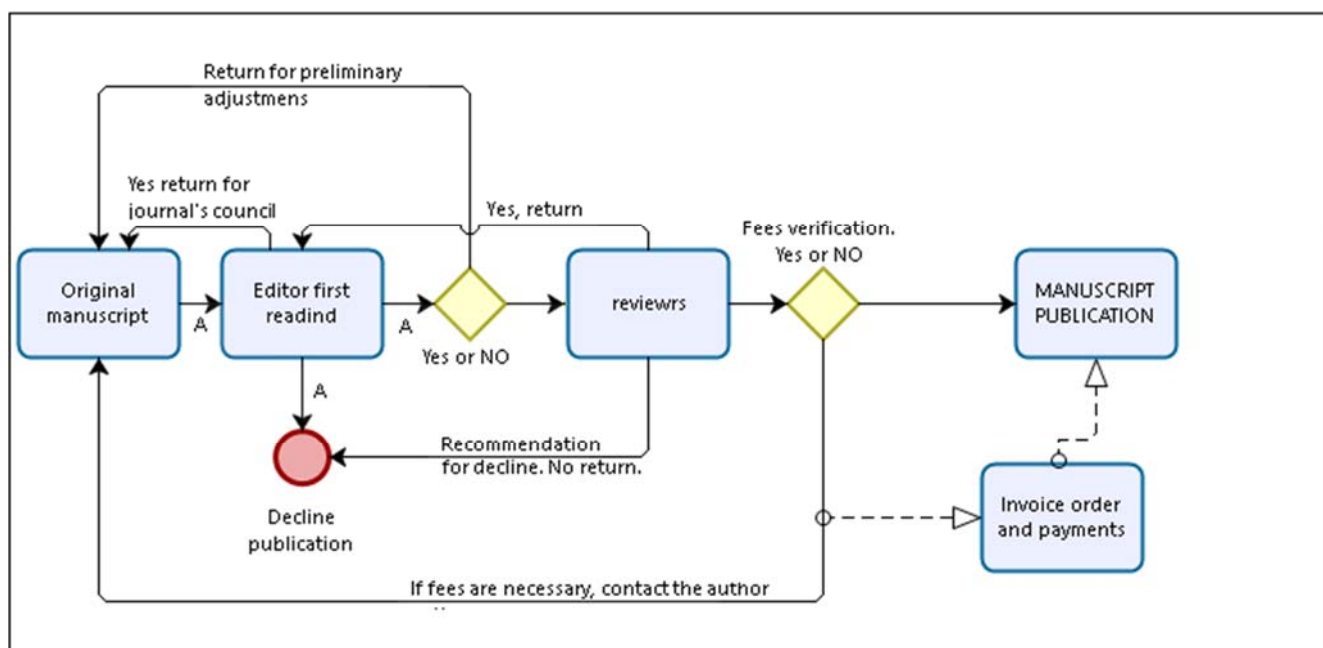

---

## PUBLICATION FEES (1), ADDITIONAL FEES FOR PUBLICATION (2), DISCOUNTS (3), AND FREE PUBLICATION OPPORTUNITIES (4)

Authors are required to pay a publication fee to share in the costs of production. The fee will be asked **if, and only if, the article is accepted for publication**. Once full payment has been made (PayPal, Bank Transfer, or Western Union Services), the paper will be published at the Ahead of Print and scheduled for the next available issue.

All waivers (as well as the publication fee requests) are **applied to the accepted papers after successful peer-review only**.

Please observe the flowchart below to understand how we work.

### 1. PUBLICATION FEES

\*Brazilian authors, USD 200

\*Other countries income groups:

High income (or nuclear-capable countries) - USD 300

Upper middle-income USD 250

Lower middle-income USD 120

Lower middle income (Heavily indebted poor countries (HIPC)) USD 100

Low-income USD 100

Low income (Heavily indebted poor countries (HIPC)) USD 80

- ✓ In order to improve the services of the journal, starting from the NOVEMBER issue of 2020, the Journal will adjust the scope in the area of Education. In this area, we will publish only Chemistry Education manuscripts. The publication fee for approved manuscripts will be unique for all nations, USD 300.
- ✓ (\*) Classification according to the World Bank list of economies (June 2017)
- ✓ \*\* Optional page formatting fee + USD 80. If you don't have time or the proper conditions to execute the formatting of your manuscript, we will find someone to do it for you.

## 2. ADDITIONAL FEES FOR PUBLICATION

### a) Proofreading and / or plagiarism

If the submitted manuscript has more than 100 grammatical errors or plagiarism greater than 5%, a fee of USD 200 will be charged. This fee does not guarantee publication of the manuscript and is non-refundable.

### b) Alteration of PDF files

After undergoing the final check of the manuscript file and Pre-Print PDF generation, a USD 100 will be charged with the authors in case they want to change something. For each new change, the fee is charged again.

### c) Acceptance Letter for article publication

The acceptance letter is an optional service of the Journal. If the authors need a document to prove that their article has been peer-reviewed and accepted for publication, they may request, upon payment of an additional fee of USD 40, an acceptance letter for publication of the article.

NOTE 1: THE LETTER OF ACCEPTANCE may be issued if, and only if, the article has undergone a complete peer-review and is considered ACCEPTED for publication. Letters will NOT be issued for newly sent articles that have not yet been appropriately evaluated and peer-reviewed.

NOTE 2: The Journal does not agree with the trade-in documents that can attest to the publication of articles that have not gone through the due process of peer-review and are legitimately considered approved for publication in the subsequent edition.

NOTE 3: Bearing in mind that the pre-printing PDF is generally already considered as proof of publication, authors must, via e-mail, justify the request for a letter of acceptance for purposes of general registration by the Journal.

- If there is no need, additional fees are not charged.

## 3. DISCOUNTS

a) **50% discount** for authors who support other journals from the team (*Southern Brazilian Journal of Chemistry* (this is a 100% free journal)), with 1 manuscript approved for publication;

b) **100% discount** for authors who support other journals from the team (*Southern Brazilian Journal of Chemistry* (this is a 100% free journal)), with 2 manuscripts approved for publication;

c) **Volume discount**, if you are an author/collaborator of the journal, that has published with us 4 manuscripts (paid your full corresponded price), your fifth manuscript will be free of charge. Later the counting cycle restart.

#### 4. FREE PUBLICATION OPPORTUNITIES

- a) Young scientists publishing the first manuscript of their career with us. Requirements: Copy of the curriculum with no publications; maximum of 2 authors;
- b) All personal related to the production of the journals, from Brazil and abroad;
- c) Longtime collaborators. Authors who have published four (4) articles with us during the past decade will be rewarded with one (1) free publication. After that, this cycle starts again, that is, for every 5 articles published, one will be free of publication fees. Thank you for choosing and trusting the Journal to publish your research.
- d) Paper considered by the Editors of high quality, priority, and relevance for the development of the society shall pay no fees. Note that this condition is a small recognition prize, not something that you may request. Thank you for your comprehension.
